The Oliver-Sharpey Lectures

ON

NEW FACTS IN RELATION TO THE PROCESSES OF NERVOUS DEGENERATION AND REGENERATION.

Delivered before the Royal College of Physicians of London on April [illegible]

BY W. D. HALLIBURTON, M.D. LOND., LL.D., F.R.S., F.R.C.P. LOND.,

PROFESSOR OF PHYSIOLOGY, KING'S COLLEGE, LONDON.

LECTURE I.

Delivered [illegible]

MR. PRESIDENT AND FELLOWS,—I have first to thank the College for the honour conferred upon me in selecting me as the Oliver-Sharpey lecturer for the present year. The College has always recognised, from the days of Harvey onwards, that scientific medicine must be grounded on physiological knowledge. The founder of this lectureship has exemplified this precept in his own lifework, and Sharpey, the great master whom the lectureship commemorates, always recognised the importance of physiology as the institutes of medicine.

Many years ago, when I was a first years student at University College, I remember Sharpey's commanding figure; for, though he had then relinquished his professorship, he continued to haunt the laboratory which had been the scene of his teaching and of his investigations. I well recollect the sad day on which his remains started from the precincts of University College to their last resting place. His name still lives not only in the memory of those whom he inspired but will be remembered in relation to his discoveries and is commemorated at his college by the foundation of the Sharpey Scholarship. Being myself one of the early Sharpey scholars, the invitation to deliver these lectures was one which was especially acceptable, and I can only trust that what I have to say will be considered worthy both of the great memory to which I have alluded as well as of the high traditions of this College.

In the days of Harvey the subject of physiological chemistry, chemical physiology, or bio-chemistry, as some prefer to term it, did not exist. The late *Sir Michael Foster* in his "History of Physiology," when speaking of Vesalius, said: "The great anatomist would no doubt have made use of his bitterest sarcasms had someone assured him that the fantastic school which was busy with occult secrets, and had hopes of turning dross into gold, would one day join hands in the investigation of the problems of life with the exact and clear anatomy so dear to him." Almost the same words might be used in reference to Harvey's attitude. The scientific men of his time paid no heed to chemical learning; they ignored or even despised the beginnings of that branch of knowledge which in later years was to become one of the foundations of physiology and the mainstay of the art of medicine. It was the work of Lavoisier in France, of Mulder in Holland, and of Liebig in Germany that first placed bio-chemistry on a sure basis, but even in Sharpey's time the disciples of this branch of science might have been counted on the fingers of one hand. Sharpey himself retained to the end the anatomical conception of physiological advance. How different things are to-day; how great have been the strides made in chemical physiology and in its sister science, chemical pathology, can be realised by even a superficial survey of modern medical literature.

A few years ago, when I had the honour of delivering before this College the Croonian lectures, I selected as my subject the chemical side of nervous activity, in which I hope I was successful in showing how chemistry has invaded even the difficult country we call the nervous system. I then indicated that although some progress had been made, even in the practical applications of that knowledge, much still remained to be done. The same is true to-day, but in the few years that have elapsed since I uttered these words a little progress has been made, and it is to some of this new work that I propose to devote the present lectures. One great charm of physiology to the investigator is that fresh facts are always being discovered, and new light is thus shed on the problems of living matter. In so far as I myself have had any small share in such work, my energies have been mainly directed into a bio-chemical groove, and it is one of these questions—nerve degeneration—to which I shall devote the first of the two lectures. That bio-chemistry is not a narrow specialism, and research on such lines usually branches out in many directions; this will be illustrated by the circumstance that for the subject of my second lecture I shall take that of nerve regeneration, in which at present there is but little to be said from the chemical point of view. In relation to both of these subjects it would have been impossible to speak at all if it were not for the assistance of certain of my colleagues. Among these I would particularly mention Dr. F. W. Mott, to whose loyal coöperation and helpful advice I owe so much. Mr. Arthur Edmunds, Dr. Rosenheim, and Miss Tebb are others to whom both Mott and myself are indebted for great assistance in several portions of our conjoint work.

One more word of introduction, and only one, before I pass to the subject proper of my first lecture. It is impossible in our present state of knowledge to avoid controversial questions. I have to-day to deal with one and to-morrow with another. Polemics are always distasteful to me and I trust that I may deal with both without a single note of personal feeling. The proverbial disagreement among doctors is especially true of physiologists, and this is really as it ought to be. Whilst knowledge is in the making there must be divergencies of opinion, and it is only by a full and free discussion of these and by the renewed research of which criticism is the stimulus that any certainty in the way of truth can be arrived at.

NERVE DEGENERATION.

It is more than 50 years ago that the elder Waller described the degeneration that occurs in nerve fibres which are cut off from the cells of which they are outgrowths. So complete and exact was his description of this phenomenon, now known as Wallerian degeneration, that in the intervening years but little has been added from the anatomical and histological standpoint to what he taught. But in order to understand completely the chemical transformations which lead to these anatomical appearances it is first necessary to know the chemical composition of the healthy nervous structures involved. It is just at this fundamental point that we meet with a great hiatus in knowledge. We know something of (because we can easily estimate it) the proportions between water and solids in the various districts of the nervous system. We know, further, that among the solids protein matter, and especially nucleo-protein, largely predominates, particularly in grey matter, but it is in relation to the phosphorised fatty constituents, the presence of which forms such a striking characteristic of all nervous material, that our ignorance is greatest. Thudichum did yeoman service in his attempts to unravel this problem, and the value of his investigations is only just beginning to be appreciated. His work is marred, it is true, by too hasty generalisations, and by such faults as are always seen in a new endeavour—faults which subsequent observers should be grateful for, as they profit by them and avoid them. No one who has not attempted to work at the chemistry of the brain can imagine the difficulties that meet one at every turn. In America Waldemar Koch, and Gies may be mentioned among those who have had the courage to enter this thorny field, and in my own laboratory Dr. Rosenheim and Miss Tebb are prosecuting similar researches. The phosphorised fats are not the only complex substances which are present. The crystalline monatomic alcohol called cholesterin is present in a free condition in considerable amount; this cannot be devoid of physiological moment, and yet absolutely nothing is known either of its mode of origin, its destination, or its function. Then there are complex nitrogenous glucosides, called the cerebrins or cerebrosides, here, again, although some of them have been separated in a fairly pure condition, analysed, and labelled with fantastic names, we have no certain knowledge either of their constitution or of their use. One notes with some regret the final disappearance of the substance originally termed "protagon" by Liebreich. This is one of the few materials that can be obtained in a crystalline form from nervous structures by cooling a warm alcoholic extract of brain, for instance. It has passed through many vicissitudes, being alternately regarded as a mixture and as a chemical individual. The work of Gies in New York and that of the workers in my laboratory have, however, finally demonstrated that it has no independent existence.

It will, however, be beside my purpose to dwell too long on the lack of the knowledge we hope to obtain some day, or to go any more fully into incomplete researches now in progress. When the day arrives of perfect knowledge in such matters there may be a very different story to tell. We must, however, take things as they are, and at any rate I think we are pretty safe in taking lecithin as a type of the phosphorised fats, and we are acquainted both with its composition and with the products of its decomposition. It is present in considerable amounts in nervous tissues and it is owing to its presence that the black staining with osmic acid of the fatty sheath of nerve fibres is mainly due. The use of osmic acid as a reagent for the detection of fat depends on the presence in the fat of oleic acid and its compounds. Oleic acid is the only representative of the acrylic series of fatty acids found in the body, and all the acids of this unsaturated series possess the power of taking oxygen from osmic acid—osmium tetroxide—and so reducing it to the condition of a lower oxide which has a black colour. Fats which are compounds of acids of the acetic series —such as palmitin and stearin—do not give the reaction. When Wallerian degeneration occurs the degenerated fatty sheath is stained much more readily with osmic acid than the healthy medullary sheath. It will strike the black colour with osmic acid even in the presence of chromic salts, and it is this circumstance that has led to the adoption of a mixture of the two acids, known as Marchi's reagent, for the detection of degenerated fibres. The intense black staining which the degenerated myelin gives is due either to an increase of the oleic acid radical or more probably to a loosening of its combination with other atomic groups, so that it is able to exert its reducing action more forcibly. Lecithin is a fat which yields on hydrolytic decomposition four groups of material. They may be represented in the following simple way:—

Lecithin + water.

(1) Fatty acids; oleic acid among the number.
(2) Phosphoric acid
(3) Glycerin
(4) Choline.

Glycero-phosphoric acid.

An ordinary fat yields only two—namely, fatty acid and glycerin. The phosphoric acid obtained contains all the phosphorus of the original lecithin, and unites with glycerin to form glycero-phosphoric acid. The fourth decomposition product—choline—is an ammonium-like base, and contains all the nitrogen of the lecithin. I dealt with these points more fully in my Croonian lectures, but it may be necessary to remind my hearers of these main facts in order to pave the way to what we are coming. I would further remind you that Mott and I showed that in degenerative diseases of the nervous system, as well as in the degeneration artificially produced in animals by the cutting of nerves, the products of degeneration pass into the circulating fluids, and can be detected there. We further showed that in a certain stage of the degenerative process in a nerve all traces of phosphorised fat disappear and the fat or fatty acid which is absorbed more slowly remains in the nerve sheath for a considerable time, and while it is present it continues to give the Marchi reaction.

THE DETECTION OF CHOLINE.

In our work we laid special stress on the importance of the discovery of choline in the blood and cerebro-spinal fluid. If this is found, there is available a definite proof of the breakdown of nervous tissues. We further indicated that the detection of choline in such situations might be of practical service in diagnosing organic nervous diseases, for functional disturbances are often difficult to distinguish from these by the observance of mere symptoms. This discovery has been confirmed by numerous subsequent observers and the expectation that the test would be diagnostically useful has also been fulfilled. On the other hand, our methods for the detection of choline have been subjected to criticism, and it has been this criticism which has stimulated us to further work on the subject and has led us to modify the tests we previously published, and also to rectify some of our conclusions. As the invention of the choline test has been hitherto the main practical outcome of our work from the clinical point of view, I take this opportunity, when I am addressing physicians, of amplifying this part of my subject by mentioning the main objections that have been raised to our work, the further examination to which we have in consequence subjected our methods, and the present conclusions at which we have arrived. I think you will find that we have succeeded in confirming all our main previous statements, and what is more important, rendering the means of detecting choline absolutely trustworthy.

The tests for choline which Mott and I chiefly dealt with were two in number. The cerebro-spinal fluid or the blood was first extracted with absolute alcohol; the alcoholic extract was evaporated to dryness and the residue again taken up with alcohol, and this operation was repeated several times in order to avoid any contamination with potassium salts. We imagined at the time that potassium salts were quite insoluble in absolute alcohol. The final residue was dissolved in alcohol again and an alcoholic solution of platinum chloride added; the yellow precipitate so produced was washed with alcohol by decantation and finally dissolved in 15 per cent. alcohol; on evaporation of this at a fairly low temperature yellow crystals (prisms and octahedra) separated out, and these consist of the double chloride of choline and platinum. The same test with slight modifications was also adopted by Donath in Germany, who was one of numerous others to confirm our results.[1]

The second test was a physiological one. It consisted in taking the final residue after alcoholic extraction and dissolving it in salt solution. When this solution is injected into the blood stream of anæsthetised animals it produces a temporary fall of arterial blood pressure; if, however, the animal has been previously poisoned with atropine the fall is either absent or replaced by a rise. This action is characteristic of choline and is quite different from the effect produced by the substances most likely to be confused with choline, which are the chlorides of ammonium and of potassium. It is, however, a test which is not available for ordinary clinical use and so special interest attaches to the chemical test which can be obtained with smaller quantities either of the cerebro spinal fluid or of the blood.

It is the chemical test which has been mainly the cause of the criticisms to which I have alluded. Some of our critics seem to have thought that we had been content to diagnose the crystals of the choline platinum compound by mere inspection, which is usually a fallacious method of identifying any crystalline substance. If our original papers are consulted it will be seen that this is not the case; in some cases where we were successful in obtaining a large supply of material we examined other properties of these crystals (their solubilities, the amount of platinum in them, &c.) and, moreover, found that on heating they gave out the odour of trimethylamine, and we further supported our statement that choline was present by performing other tests in addition. Some critics—for instance, Vincent and Cramer—regarded our contentions as "*a priori* improbable" and "scarcely conceivable," but they did not examine either pathological blood or cerebro-spinal fluid in order to determine whether the facts as we had stated them were correct or not.

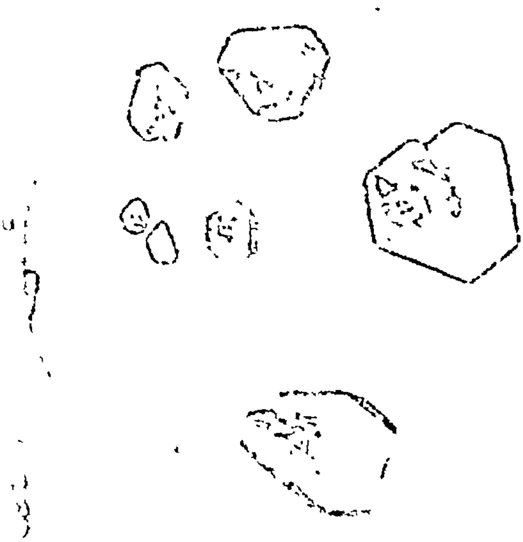
The first serious piece of criticism came from Guy's Hospital. Allen and French pointed out that the treatment with absolute alcohol did not get rid of potassium salts entirely; and as the platino-chloride of potassium is exactly similar in form to that of choline platino-chloride inspection of crystals obtained by our method was insufficient to distinguish them. Inspection of crystals is usually the only test which a clinical observer has time for; and if the amount of material is small it is probably the only available test. On account of this uncertainty Allen and French abandoned the platinum test entirely and adopted instead a modification of the iodine test for choline in which there is no risk of such confusion. By the help of this reaction Allen subsequently confirmed our statements concerning the presence of choline in the blood of patients suffering from acute degeneration of nervous structures

The accompanying drawing from a photograph (Fig. 1) will illustrate the impossibility of identifying the two platino-chlorides in question by their crystalline form. At this lapse of time I cannot remember which of the crystals are those composed of the choline and which of the potassium compound. They are quite indistinguishable by mere inspection; but they can be distinguished, as I shall presently show, and were actually distinguished in the specimen from which the photograph was made. Shortly after Allen and French published their observations a paper by Mansfeld appeared in one of the German journals criticising Donath's results on much the same lines. I thought, therefore, it was high time for us to take up the matter once more, and I therefore placed it in the hands of Dr. Otto Rosenheim, whose knowledge of chemistry and chemical technique is much superior to my own, and he carried out the research in my laboratory. In the course of his work he came to the conclusion that the solubilities of potassium and ammonium salts in absolute alcohol and of their platino-chlorides in 15 per cent. alcohol, though small, were nevertheless such as to make a contamination of the final choline platino-chloride, with platino-chlorides of potassium or ammonium, a possible source of error. It was therefore necessary to search for other tests for choline which are not given by these inorganic salts. As an outcome of his work he discovered three such tests, but I shall be content here with describing one only, since it is simple and easily applied, and, moreover, is absolutely decisive. Like Allen's, it is a modification of the iodine test and it is performed in the following way. A strong solution of iodine in potassium iodide is added to a preparation of the choline platino-chloride crystals; these then alter in a characteristic way, and the change may be watched with the microscope. In the course of a minute or so the yellow crystals shown in Fig. 1 disappear and their place is taken by dark-brown plates and prisms in large quantities. They show marked dichroism, they are doubly refracting, and have a superficial resemblance to the well-known hæmin crystals. Their appearance is depicted in Fig. 2. They are composed of a periodide of choline ($C_5H_{14}NOI.I_4$), but are extremely unstable, and if the slide is allowed to stand so that the liquid gradually evaporates the crystals begin to disappear, and their place is taken by brown oily droplets, or sometimes clear spaces showing the skeletons of the crystals are seen. This indicates the formation of a lower iodide and the appearance is depicted in the next figure (Fig. 3).

---

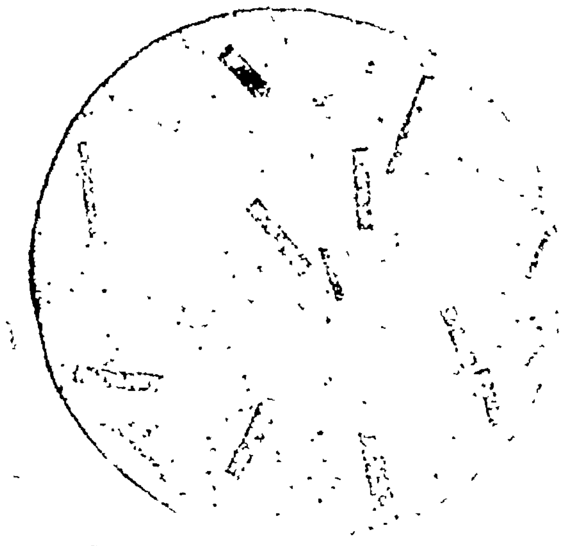
[1] Donath's statement that choline is similarly also found in the fluids of epileptics requires confirmation. If the diagnosis of epilepsy in these cases was correct, and the existence of choline is confirmed, it appears necessary to remove epilepsy from the list of functional diseases.

FIG. 1.



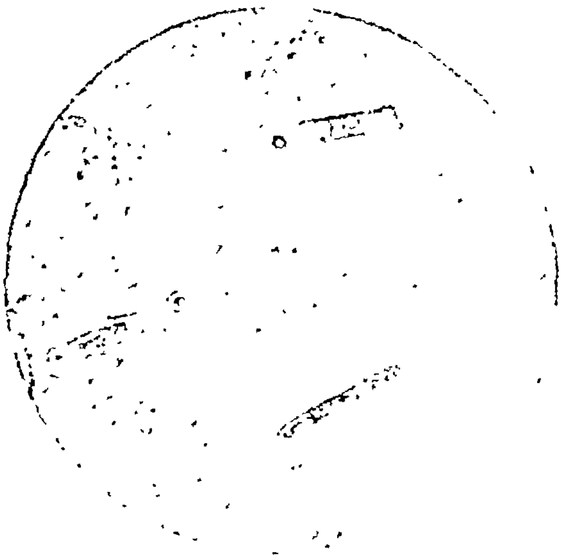
Crystals of platino-chloride of choline and platino-chloride of potassium on the same slide. (From a photograph by Otto Rosenheim.)

FIG. 2.



Photomicrograph of the crystals of choline periodide. (O. Rosenheim.)

FIG. 3



This shows the disintegration and the formation of oily droplets which occurs when the choline periodide slide is exposed to the air. (From a photograph by O. Rosenheim.)

If, now, a fresh drop of the iodine solution is added the crystals gradually form once more and their formation and disappearance can be watched repeatedly. If platino-chlorides of potassium or ammonium are present on the same slide they remain unchanged under the action of the iodine solution. It was possible by this simple test to detect choline in 20 cubic centimetres of blood when choline had been added in the proportion of 1 to 20,000. When five cubic centimetres of blood containing choline in the proportion of 1 to 2000 were used the whole field was covered with crystals which could be seen with the naked eye.

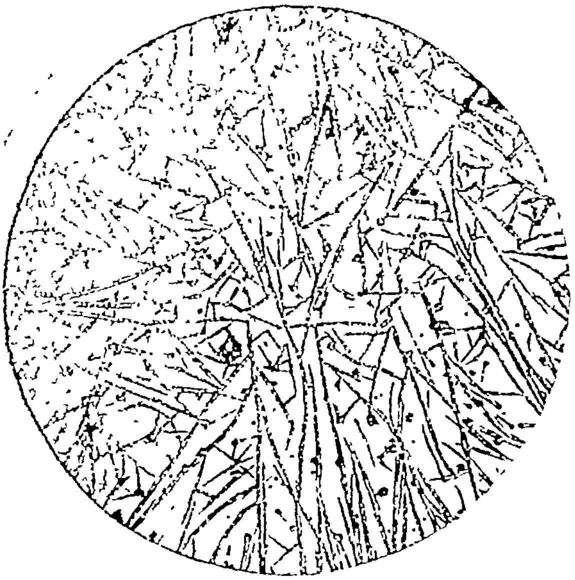
In the same number of the *Journal of Physiology* in which Rosenheim published these interesting and striking results Donath answered his critics by publishing another distinctive character of the crystals of the platino-chloride of choline. They are doubly refracting and so appear bright in the dark field of the polarising microscope and show changes in illumination when they are rotated in the field. In this way every microscopic fragment of the choline platino-chloride is rendered visible which by ordinary microscopic methods might escape detection owing to their transparency. The platino-chlorides of potassium and ammonium do not exhibit this phenomenon. Donath puts his case very well when he says:—

> The occurrence of inorganic chlorides which have hitherto interfered with the testing for choline by the platinum reaction on account of their slight solubility in absolute alcohol is a circumstance which

has lost its terrors, so much so that an actual addition of potassium-chloride has become part of my method, and causes no difficulty when the polarisation test is applied.

He then proceeds to give a list of cases where he has examined the cerebro-spinal fluid removed by lumbar puncture from patients suffering from various nervous diseases, and illustrates his results by a series of photomicrographs showing the crystals under various positions in the field of the polarising microscope. Dr. Rosenheim has confirmed these statements and the next figure (Fig. 4) illustrates the appearances observed.

FIG. 4.



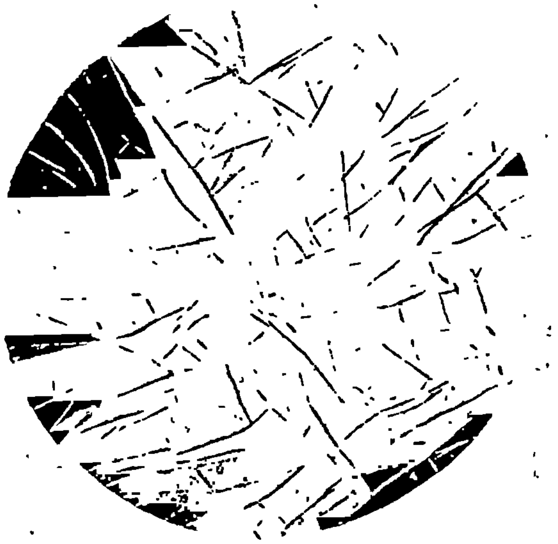
Preparation of crystals of the platino-chlorides of choline (needles) and of potassium (octahedra) obtained from a specimen of cerebro-spinal fluid from a case of general paralysis of the insane. (O. Rosenheim.)

In Fig. 4 the crystals of the platino-chloride of choline are seen as separated from an actual case of pathological cerebro-spinal fluid. In this case they were crystallised from an aqueous solution and have taken the needle-like form they usually exhibit when crystallised in this way. Mixed with them are seen a number of small octahedra of the platino-chloride of potassium. Fig. 5 shows the same preparation under polarised light; the crystals of the choline salt show up as bright needles, but the crystals of the potassium salt have disappeared from view. The crystals of the choline salt in this case further gave Rosenheim's new iodine reaction. In some cases Rosenheim made out another fact which is not devoid of significance. If he obtains from cerebrospinal fluid which contains choline a slide of the crystals of the mixed platino-chlorides and places it under the field of the polarising microscope, the inorganic platino-chlorides exhibit no double refraction but a large proportion of the crystals present show the phenomenon. If he then subjects the same slide to his iodine test many of the doubly refracting crystals are transformed into the brown crystals of the periodide of choline, but some remain unaltered and others yield crystals of different form from the choline periodide. In other words, some of the doubly refracting crystals are not choline compounds but probably crystals of other organic platino-chlorides. This is only what one would expect. Mott and I were always from the first careful to point out that choline is not the only product of nervous breakdown; the complex chemical structure of nervous material to which I have alluded in some of the earlier passages of this lecture would lead one to suppose that the cleavage products which are liberated during the degenerative process would be exceedingly numerous. We called attention, among other points, to the great increase of the nucleo-protein which passes into the cerebro-spinal fluid in such circumstances. The importance of the detection of choline arises because [illegible] numerous substances be detected with comparative ease. Its presence indicates the breakdown of one of the best known of the constituents of nervous matter (lecithin), but suggests that it must be accompanied by the presence of numerous other similar and even dissimilar compounds.

During the last year Dr. Mott has sent from Claybury Asylum a great number of specimens of cerebro-spinal fluid to Dr. Rosenheim, and the latter has subjected them to his new tests. The number of specimens of blood similarly sent has been small, and hitherto choline has only been detected in one of these; they were in the main from cases where choline would hardly be expected to occur, for, as Mott pointed out, active degeneration must be recent for the test to be a decisive one. But the examinations of the cerebro-spinal fluids have been fully satisfactory and a sufficient number of positive results have been obtained to corroborate the views of Mott and myself. I do not propose to anticipate any further Dr. Rosenheim's full paper on the subject except to say that it has ultimately been found better to shorten the procedure of testing by applying the iodine reaction direct to the alcoholic extract of the fluid. There is no necessity to prepare the platino-chloride first and apply the iodine test to those crystals. It was found that some of the other bases already referred to, the identity of which is still uncertain, often by their presence interfere with the iodine reaction when it is applied to the mixtures of the crystalline platino-chlorides. This is an additional reason for using the test in the direct manner.

I had, happily, kept a considerable number of the preparations of crystals which Mott and I had made years ago and from which we drew our previous conclusions. On examining these afresh by the new means of identification we now possess I have found that without doubt they do not consist wholly of the choline compound but contain a considerable admixture of inorganic platino-chlorides, especially the platino-chloride of potassium. We, however, still hold that the obtaining of a large crop of crystals, whether they be those of the choline salt or a mixture of the potassium and choline salts, is diagnostic of extensive breakdown in nervous tissues. The contrast between such cases and the insignificant yield from normal blood is most striking. This is quite intelligible when we take into account the very high percentage of potassium that nervous tissues contain. This has been amply demonstrated by the microchemical work of Macallum and of Macdonald. The rôle which Macdonald assigns to the potassium salts in nervous phenomena it is unnecessary to discuss here, interesting and important as his views are. This has suggested to us a new piece of work which has only just been started—namely, the actual estimation of the potassium in the cerebro-spinal fluid and [illegible] of acute degenerative diseases of the nervous

FIG. 5.



The same preparation in the dark field of the polarising microscope; the crystals of the choline salt are bright; but the crystals of the potassium salt have become invisible. (O. Rosenheim.)

system in comparison with the normal. I am sorry I cannot at present give any final figures but, so far as the preliminary work goes, it indicates a considerable increase of the potassium in those cases where disintegration has occurred and where choline is also discoverable.

THE PHYSIOLOGICAL TEST FOR CHOLINE.

I have devoted so much time to the chemical test for choline because that is the one so obviously suitable for clinical work. The physiological effect on the blood pressure that choline exercises is, however, not devoid of interest, and a brief mention of some recent work in this direction will conclude what I have to say. Swale Vincent, in his earlier work on the physiological action of extracts of nervous tissues, found that the intravascular injection of such extracts caused in anæsthetised animals a considerable fall of blood pressure. I had simultaneously published similar results and attributed the fall to the presence of choline. Vincent, however, denied that choline was present. He subsequently, with Cramer, amended this statement, but was of opinion that the choline present was in the form of dicholine anhydride. The existence of this compound is very problematical and the analytical evidence presented is not very convincing; still the suggestion that compounds or modifications of choline may exist is not devoid of interest. Vincent and Cramer also found what I had missed—namely, that there are other substances present in such extracts which are readily soluble in ether and which produce a much more powerful depressor effect on the blood pressure than choline, and that in the case of such substances the depressor effect is not abolished by atropinisation. The identification of these other materials was not attempted. It is quite possible that these substances are absolutely distinct from choline; and, on the other hand, the view is permissible that they are choline derivatives. This second view gains point from a study of some experiments which Reid Hunt and Taveau brought forward at the meeting of the British Medical Association in Toronto last year.

Dr. Hunt is one of numerous American pathologists who have repeated and confirmed the original statements of Mott and myself and has thrown himself into the choline controversy with characteristic transatlantic enthusiasm. He has prepared and studied the physiological action of as many as 19 compounds of choline and suggests the possibility that some of these may be formed in the body. Some of them are more and others less active than choline itself, the most powerful is acetylcholine; this is one hundred times more active in producing a fall of blood pressure than adrenalin is in producing rise; the injection of a few cubic centimetres of a solution containing it, diluted with one hundred million times its volume of water, produces a distinct effect in a rabbit. The action of acetyl choline is not annulled by atropine, and it is capable of overcoming the effect of adrenalin. On the other hand, some of the choline derivatives examined were less powerful than choline itself; the introduction of a phenyl group, for instance, diminishes its depressor effect. As an outcome of his work Dr. Reid Hunt recommends two new tests for choline; one is the formation of the acetyl compound to render the physiological test more sensitive, the other is the formation of the benzoyl compound; this gives a distinctive crystalline platinum salt which cannot be confused with the platino-chlorides of ammonium or potassium. I have not actually tested these methods myself but I think I have said sufficient to show that in the future those engaged in research will have no lack of methods to render the testing for choline a matter of no difficulty.

The bibliography of this subject up to 1905 will be found very completely given in my article on Die Biochemie der Nerven in the *Ergebnisse der Physiologie*, vol. iv., p. 23, 1905. The principal papers which have appeared since are the following:—J. Donath: *Journal of Physiology*, vol. xxxiii., p. 211; Rosenheim: Ibid., p. 220. Reid Hunt and Taveau: *Brit. Med. Jour.*, 1906, vol. ii., p. 1783. Several observers have surmised that the breakdown of lecithin is due to the activity of a ferment; the ferment has, however, not been isolated. Marinesco (*La Presse Médicale*, Feb. 16th, 1907) suggests that the ferment is formed by the neurilemmal cells, which actively multiply during Wallerian degeneration.

HOSPITAL SUNDAY IN CARDIFF.—April 28th was observed in Cardiff as "Infirmary Sunday." As the result of last year's collection £777 were raised for the funds of the Cardiff Infirmary.

A Lecture

ON

CEREBRO-SPINAL FEVER.

Delivered at the London Hospital on March 21st, 1907.

BY CECIL WALL, M.A., M.D. OXON.,
M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE HOSPITAL AND TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

GENTLEMEN,—The study of cerebro-spinal fever is always interesting; at the present time it has become exceptionally important owing to the increase in the number and severity of the cases occurring in various parts of the country. I propose, therefore, to discuss with you certain points which are of value in the clinical diagnosis and will preface my remarks with a few words on the morbid anatomy and the nomenclature of the disease.

Cerebro-spinal fever is the result of an acute meningo-encephalitis; in the very early stage at the post-mortem examination *little abnormal may be seen save an intense*, perhaps hæmorrhagic, inflammation of the pia mater and arachnoid covering the brain and spinal cord with evidence of inflammation of the cortical grey matter of the brain. At a later stage a more characteristic condition may be found, the inflammation of the pia mater and arachnoid being associated with a purulent exudate between them; this exudate is most marked where the subarachnoid space is widest, so that purulent collections are formed on the sulci of the cortex, in the lymph cisterns at the base of the brain, and in the spinal cord. If death occurred at a late stage of the disease an extensive serous exudate might be found distending the basal cisterns, the subarachnoid space surrounding the spinal cord and the lateral ventricles of the brain (with which the subarachnoid space communicates through the foramen of Majendie), the fourth ventricle, the iter, and the third ventricle. The distension of the ventricles leads to flattening of the cortical convolutions and obliteration of the subarachnoid space. The purulent exudate is thus driven from the surface of the brain to the base and is found in large quantities only there and in the spinal canal.

It is thus possible to distinguish three stages in the disease. In the first stage, when the patient has died in less than 48 hours from the onset, there is an acute, possibly hæmorrhagic, meningo-encephalitis without exudation. In the second stage the meningo-encephalitis is associated with a purulent exudate into the subarachnoid space. This condition is usually found if the patient has died within about 14 days from the onset. In the third stage there may be an extensive serous effusion distending the subarachnoid space and the cerebral ventricles. The purulent exudate may be collected in the wider arachnoid spaces or may have disappeared more or less completely. This condition may be found as early as 18 days from the onset and may persist for weeks or months and sometimes is the cause of the condition known as chronic hydrocephalus. Other morbid conditions may be present but need not be detailed here.

Acute general meningo-encephalitis is, without doubt, always the result of infection by some micro-organism; the meningococcus, the pneumococcus, and streptococci are those most usually present. In the disease known as epidemic or sporadic cerebro-spinal fever the meningococcus is said to be the causal agent though the proof is not yet quite complete. Cerebro-spinal meningitis due to the meningococcus is an endemic disease of which we are seldom without some examples in this hospital; under the name of posterior basic meningitis or cervical opisthotonos of infants it is by no means rare. Posterior basic meningitis is the term applied to a comparatively mild form of the disease occurring in children in which a fatal result tends to occur in the third stage. It is, perhaps, unfortunate that the name still persists seeing that it suggests but one of the accidental characters of a general acute meningitis. At times, especially in the spring, the cases occur much more frequently and occasionally the increase in number and severity of the symptoms seems to justify the term epidemic.

The word epidemic suggests in the minds of most that the infection may be transmitted from person to person by contact or by fomites. We read of past epidemics of a disease presenting symptoms similar to those produced by infection with the meningococcus, in which evidence of transmissibility by contagion was strong, but since the introduction of the bacteriological methods of diagnosis no epidemic has occurred where such evidence has been forthcoming. In 1905 there was an outbreak of cerebro-spinal meningitis at Irthlingborough, in which spread by contagion was probable. This was investigated by the Local Government Board, but unfortunately the bacteriological evidence that the meningococcus was responsible was based on the examination of the nasal secretion of two cases only and can scarcely be deemed conclusive. In the sporadic cases with which we are familiar instances of infection by contact are practically unknown; there seems to be no clue to the mode of infection, though the nasal mucosa is commonly suspected. Hence we are driven to the conclusion that either the meningococcus may at times, owing to unknown circumstances, become more virulent, or some other organism may be responsible for those epidemics where transmissibility by contagion is a marked feature of the disease. Further information upon this point is urgently required; it is to be hoped that the action of the London County Council in requiring notification of the disease may determine the question.

The recognition of the disease at the bedside is the point to which I wish particularly to draw your attention. It is convenient to group the symptoms and signs according to the underlying pathological state. In the first place, cerebro-spinal fever is a general disease with definite local manifestations. Of the incubation period we know nothing; the invasion is usually sudden, with fever, vomiting, rapid wasting, and general febrile symptoms; in the malignant type, as with other specific fevers, a purpuric rash may develop which has led to the name "spotted fever" and in the past has frequently led to confusion of the disease with typhus fever. Other symptoms and signs are referable to the local disease: acute encephalitis occurring after development of the cortex cerebri leads to headache and profound alterations of consciousness, such as delirium or coma, and to spontaneous movements of the limbs, convulsions, and paralysis. Dissociation of movements of the eyeballs is common in the young and can be explained as reversion to a previous stage of development consequent upon the removal of the recently acquired cortical control. Blindness without alteration of the pupillary light reflex and deafness may develop and persist for a long time; the usual cause seems to be the encephalitis. In the young child up to the end of the first year of life the functions of the cortex are so little developed that their abolition or impairment by encephalitis may escape notice; many cases of the so-called posterior basic meningitis of infants afford examples in proof of this statement.

Inflammation of the meninges can only be recognised by the reflex muscular contraction which tends to prevent any mechanical disturbance and by the implication of sensory nerves with consequent referred pain. There are two situations where movements of the body lead to movements of the meninges; in flexion and extension of the head the cerebellum slides up and down the posterior surface of the medulla and unfolds or folds the arachnoid which forms the bridge between them. If the arachnoid be inflamed the muscles at the back of the neck contract to prevent such movement; resistance against antero-posterior movement of the head without resistance to movements of rotation about a vertical axis is a sign very commonly present when there is inflammation of the meninges at the base of the brain. Sometimes the contraction is so extreme that the occiput actually touches the skin between the scapulæ and there is a general spinal opisthotonos with great rigidity. The other situation in which mechanical disturbance of the meninges results from movements of the body is in the lumbar and sacral regions; if the sciatic nerve be stretched the traction is transmitted to the spinal meninges. This is the explanation of the sign of spinal meningitis described by Kernig; if one hip joint be flexed to a right angle, the other being kept extended to prevent a fallacy from tilting of the pelvis, and the knee-joint be then passively extended, the hamstrings will reflexly contract and prevent extension of the knee-joint beyond a right angle and a half (135°) when there is acute inflammation of the spinal meninges. These two signs are very frequently present in cases of acute cerebro-spinal meningitis. Referred pain due to implication of the nerve roots in the inflammatory process explains the remarkable cutaneous tenderness which may be present in those patients sufficiently conscious to appreciate it.

We can now pass on to the consideration of the signs by which we can recognise a marked increase in the cerebro-spinal fluid which may occur in the third stage of the disease. Increased intracranial pressure leads to vomiting, spasmodic retraction of the upper eyelids, impairment of the cerebral functions, and not infrequently to swelling of the optic discs; if the fontanelle be still patent its tenseness may give direct evidence of the rise of pressure; in very young infants before the sutures between the skull bones have united there may be separation of the bones.

We have now discussed in general the symptoms and signs likely to be present in a case of acute cerebro-spinal meningitis: the etiological diagnosis remains to be considered. This can only be established absolutely by the identification of the infecting organism. The method employed to obtain material for examination is to perform lumbar puncture in the early stages; the fluid thus obtained will probably be scanty, moderately albuminous, and containing many polymorphonuclear leucocytes. The meningococcus, if present, may be identified by cultivation and may be seen within the cells in smear preparations. In the later stages the fluid may be under considerable pressure and a large quantity may be obtained; the albumin will be less in amount and the cellular elements more scanty and the meningococci more difficult of identification and cultivation. In this stage symptoms due to increased intracranial pressure may be remarkably alleviated by lumbar puncture.

I will now recapitulate the chief clinical characters of the disease. Patients of any age may be attacked but it is much more common in children. In sporadic cases there is no evidence of spread by contagion, and the proof of such spread in epidemics proved to be due to the meningococcus is inconclusive. The onset is usually sudden, but in young children the presence of symptoms due to the encephalitis may be difficult to recognise. The common mode of invasion is by headache, vomiting, cutaneous and muscular tenderness, convulsions with delirium, or other profound mental disturbance; there is usually some fever, the temperature being from 102° to 105° F. Rigidity of the neck, retraction of the head, and Kernig's sign are frequently present; dissociated movements of the eyeballs may occur; optic neuritis is uncommon. Wasting is rapid, and petechial or herpetic eruptions may develop. Lumbar puncture performed at this stage may be unsuccessful or a small quantity of turbid fluid may be withdrawn. This first period of the disease corresponds with the first and second stages of the pathological development; it lasts from two to ten days and the pyrexia often terminates by crisis, and a convalescence, generally tedious, may be established. Frequently the first stage merges, with or without a brief period of apparent improvement, into the stage of internal hydrocephalus. If this occurs on about the eighteenth day from the onset of the disease vomiting, spasmodic retraction of the upper lids, and a recrudescence of the mental disturbance, perhaps with convulsions, will develop and the temperature will become irregular. In young babies these symptoms may be absent and the increase in cerebro-spinal fluid may be recognised only by the rapid enlargement of the skull with bulging of the fontanelle and starting of the sutures. Death may occur during this stage of internal hydrocephalus or the condition may become chronic, or recovery, partial or complete, may be the result. With partial recovery the possible after-effects are numerous: persistent blindness or deafness with consequent mutism, a dementia akin to that of general paralysis, imbecility, epileptiform convulsions, spastic paraplegia, or diplegia may be the legacy of the disease.

In the early stage the diagnosis has to be made most usually from influenza, typhus, and typhoid fever. Influenza may closely simulate meningitis in the suddenness of onset, in the headache, and in the pyrexia; the absence of evidence of abolition of the cerebral function and of the signs of basal and spinal meningitis are points upon which stress should be laid. Lumbar puncture may be necessary to settle the diagnosis. In former days typhus fever and meningitis were frequently confused; in modern times typhus fever is so rare that the difficulty in diagnosis does not often arise. The gradual onset of typhoid fever, the apathetic state, and the development of the typical signs and symptoms with the agglutination reaction usually serve to distinguish the condition. I have known meningitis incorrectly suspected when the neck has become rigid owing to inflamed cervical

TABLE OF 63 DETERMINATIONS OF THE OPSONIC POWER OF THE SERUM IN CEREBRO SPINAL FEVER.

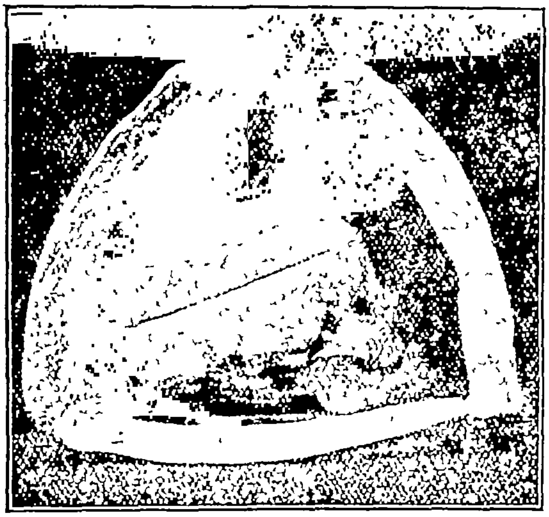
In only a limited number of these patients were cultures made from the cerebro-spinal fluid or blood. The positive results are given in the column headed "Remarks."

The chest was flattened in front but wide antero-posteriorly and on deep inspiration was raised as a whole, expansion being very slight. At the level of the nipples it measured in full inspiration 33 inches and in forced expiration 32 inches. The normal curvatures of the spine were diminished rather than increased and the spine was only a little more rigid than normal for his age. Both humeri were thickened and curved forwards and outwards; the bones of the forearms seemed curved with the convexity dorsal. These changes were more marked in the left arm than in the right. The bones of the hands appeared natural and there was no clubbing of the fingers. The femora were exceedingly curved outwards and forwards, the right rather more than the left. The tibiæ likewise were curved forwards and were very massive in their whole length and overhung the ankles. The antero-internal surfaces were very wide and the margins rounded. There was œdema of the shins with pitting on pressure. The curvature of the bones of the lower extremities caused a bowing of the legs so that the internal condyles were separated by three and a half inches as he stood with feet together. The distance from the anterior superior iliac spine to the internal malleolus was 31¼ inches on the right and 32¼ inches on the left.

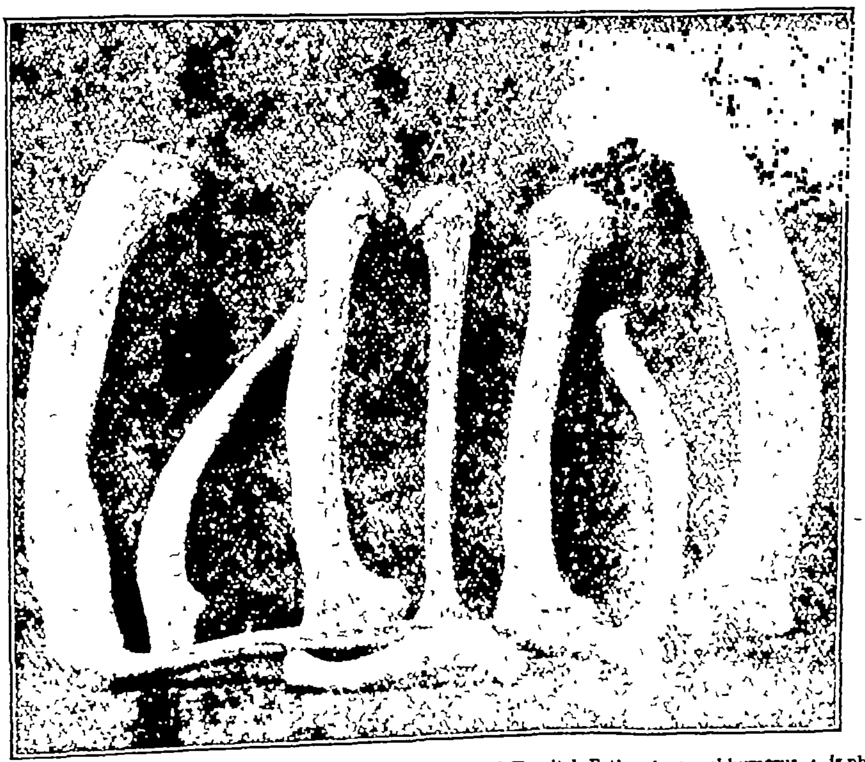
FIG. 2.



Skull and longitudinal section of tibia and humerus in the Museum of the Royal United Hospital, Bath. Typical osteitis deformans.

There was a crackling grating to be felt in the knee-joints on movement. The knee-jerks were present and not exaggerated. The pupils were equal and reacted normally to light and on convergence. There was a faint systolic murmur at the heart's apex not conducted to the axilla and the heart did not appear to be enlarged. The lungs were slightly emphysematous and whilst in hospital a cough developed and a few scattered râles could be heard in the chest, chiefly posteriorly. The abdomen was short and broad and crossed inferiorly by a deep sulcus. The liver and spleen could not be felt. There were double incomplete inguinal hernia and a hydrocele on the right side. The superficial lymphatic glands were not enlarged. His speech was slow and monotonous and his gait clumsy and waddling. The urine was clear and contained neither albumin nor sugar. The red blood cells numbered 3,416,000; the white cells 8000 per cubic millimetre. A differential count of the leucocytes showed: polymorphonuclears, 61 per cent.; lymphocytes, 24 per cent.; large mononuclears, 14 per cent.; eosinophiles, 1 per cent.; basophiles, none; and myelocytes, none. The x rays showed very beautifully the thickening and curvature of the long bones which had been discovered by inspection and palpation. The bones of the hands did not appear to be affected.

FIG. 3.



Bones from same collection of specimens in the Museum of the Royal United Hospital, Bath. A normal humerus, A, is photographed in the centre for comparison.

This patient's pains continued with varying severity during the seven weeks' course of hydrotherapeutic treatment that he underwent here but on the whole were not at all relieved. In a letter which I had from him in November he writes: "I am sorry to inform you that I feel the pains in my legs very much of a night; when I am lying in bed my knee-joints and my ankle-joints ache so much so that I scarce know where to lay them."

Sir James Paget[2] in a second communication on osteitis deformans five years after his first, having in the meantime seen seven additional instances of the disease, sums up his conclusions as follows: "In all the cases I have seen the general appearance, postures, and movements of the patients have been so alike that these alone might often suffice for diagnosis of the disease. The most characteristic are the loss of height indicated by the low position of the hands when the arms are hanging down, the low stooping with very round shoulders, and the head far forwards and with the chin raised as if to clear the upper edge of the sternum; the chest sunken towards the pelvis, the abdomen pendulous; the curved lower limbs held apart and usually with one advanced in front of the other and both with knees slightly bent; the ankles overhung by the legs and the toes turned out. The enlarged cranium, square looking or bossed, may add distinctiveness to these characters and they are completed in the slow and awkward gait of the patients and in the shallow costal breathing, compensated by wide movements of the diaphragm and abdominal wall and in deep breathing by the uplifted shoulders."

Professor Osler,[3] in the sixth edition of his "Principles and Practice of Medicine," mentions that about 67 typical cases are on record and that he himself has seen four. He says the disease is characterised by "enlargement and forward projection of the head, dorso-cervical kyphosis, prominence of the clavicles, spreading of the base of the thorax, a relative increase in the width of the hips, and an outward and forward bowing of the legs"—a definition taken from an exhaustive paper on the subject by Packard Steele and Kirkbride in the *American Journal* of 1891.

Except for the absence of kyphosis and forward projection of the head the case just related agrees very well with these descriptions and may be regarded as a typical example of the disease. In the case of some of the bones the x rays showed that the thickening and curvature were greater than had been suspected, and examination in this way might be of diagnostic value in the early stages of the disease.

In the Museum of the Royal United Hospital is a collection of bones which was presented by the late Mr. R. T. Gore, surgeon to the hospital, in the year 1863, nine years before Sir James Paget published the description of his cases. These were labelled, "From a man aged 60, the subject of rickets in early life," and comprise a skull, a scapula, clavicle, two humeri, a radius and ulna, femur, tibia and fibula. They show very typically the changes wrought by the disease which now goes by the name of osteitis deformans. The circumference of the skull is 58·7 centimetres and the distance from nasion to inion over the top of the skull 38·2 centimetres. The outer surface of the bones of the skull, including those of the face, is finely porous. In the region of the bregma there is a raised keel-like thickening of bone and there is a rounded boss on the vertex in the right occipital region. The lacrymal bones are missing. There are traces on the external aspect only of the coronal suture for about one and a half inches on each side. The fronto-malar suture is distinct but the other articulations of the malar bones have disappeared. The naso-frontal and naso-maxillary sutures are fairly well marked and part of the inter-nasal remains. With these exceptions all the sutures are obliterated. A horizontal section of the skull above the temporal fossæ and three and a half inches above the inion shows that the thickness of the bone varies from half an inch at the sides to three-quarters of an inch at the occipital end and in front of each temple. Towards the internal aspect the bone is dense and white, but towards the outer table it becomes in parts loose and friable. The facial bones do not appear to be much thickened and the orbital and nasal cavities are not encroached upon, though the hard palate and interior of the orbits are rougher and coarser than natural. Inside the cranium the bones do not present the fine porous appearance but the number of nutrient foramina is greatly increased and the grooves for the arteries are much deepened. The scapula and the long bones are much thicker and more curved than normally. As an illustration it may be mentioned that each humerus weighs more than twice as much as a healthy bone of the same length and the girth of the bone at its middle is four and a quarter inches, instead of the normal two and a half. The girth of the shaft of the femur at its middle is five and three-quarter inches and the bone is so curved outwards and twisted in its long axis that the upper and lower articular surfaces face in almost parallel directions. The shafts of all the long bones are white, nodular, and massive, and present an appearance of rugged strength and hardness which causes them at a short distance to look as though hewn out of stone. The nodules are in the main smooth and rounded, but in parts, as, for instance, the upper end of the humerus, are craggy and irregular. The nutrient foramina are increased in size and on close inspection numerous other foramina are to be seen, whilst in places, especially towards the extremities, are patches where the surface of the bone is finely porous. The articular surfaces and extremities are also increased in size, but not quite in proportion to the increased thickness of the shafts. Longitudinal sections of a humerus and tibia show that the medullary cavities are very irregular and dilated, that the cancellous tissue has almost completely disappeared from the ends of the bone, and that the walls of the shaft are dense and thick. In the museum there is also a portion of one radial artery from the same man showing its conversion into a rigid calcareous tube. Sir James Paget mentions that in the first case which he described "in the arteries of the lower limbs there was extensive atheromatous and calcareous degeneration."

Bath.

A CASE OF PRIMARY SARCOMA OF THE LIVER IN A CHILD AGED FOUR MONTHS.

BY E. W. SCOTT CARMICHAEL, M.B. EDIN., F.R.C.S. EDIN.,
ASSISTANT SURGEON, ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH
AND
HENRY WADE, M.B. EDIN., F.R.C.S. EDIN.,
CONSERVATOR, ROYAL COLLEGE OF SURGEONS MUSEUM, EDINBURGH; ASSISTANT PATHOLOGIST, ROYAL INFIRMARY, EDINBURGH.

THE rarity of undoubted cases of primary sarcoma of the liver seems to us to warrant the publication of the present one. Arnold has recorded two and has collected the particulars of 26 other cases of possible sarcoma in the liver. The true nature of the majority of these is, however, as he has pointed out, extremely doubtful from the scanty clinical history given, and the absence in many of them of any record of a microscopical examination. Since the publication of the above article we have been able to obtain records of 11 other cases in which the examination of the tumour left no doubt as to its being a primary sarcoma of the liver.

The interest of the case recorded by us consists in the occurrence of an extensive and diffuse primary sarcoma of the liver in a child, aged four months, who was apparently healthy at the time of birth, but subsequently manifested signs of extremely rapid enlargement of the organ owing to the growth of the neoplasm, such as clinically to favour the diagnosis rather of an inflammatory condition than the development of a new growth. The history of the present case was as follows:—

A male child, aged four months, was admitted to Charteris Ward of the Royal Hospital for Sick Children, Edinburgh, on Sept. 10th, 1906, under the care of Dr. T. M. Burn-Murdoch. Swelling of the abdomen had been noticed previously for a fortnight, and although the child had been inclined to vomit since his birth, he was well nourished and healthy. He was the youngest of 12. A week before admission the abdomen was observed to enlarge rapidly and the child seemed to suffer considerable pain. He did not sleep well and constantly drew up his legs. On admission there was marked distension of the abdomen, especially in the upper part, the left hypochondriac region being somewhat more prominent than the right. The superficial abdominal veins were much distended. The temperature was normal, the pulse being 130. The abdominal circumference at the umbilicus was 52½ centimetres. An examination of the blood showed that the red blood corpuscles numbered 4,000,000 per cubic millimetre and the white blood corpuscles 24,000. There was no relative increase in any individual form of leucocyte. After admission the condition of the child became rapidly worse, the abdominal swelling increased, so that in three days the circumference measured 57 centimetres, and was associated with severe respiratory embarrassment. The liver extended downwards into the right iliac fossa, the lower margin of dulness passing from this position upwards and to the left below the umbilicus. A well-marked notch could be felt to the left of the umbilicus, which seemed to separate the left lobe from an enlarged spleen.

---

[2] Transactions of the Royal Medical and Chirurgical Society, vol. lxv.

[3] The Principles and Practice of Medicine, [illegible], Appleton.

An exploratory laparotomy was performed on Sept. 13th, the abdomen being opened in the right linea semilunaris, above and below the umbilicus. The liver appeared of a purple mottled colour, soft and elastic in consistence, but homogeneous throughout. A trocar and cannula were pushed deeply into the liver substance through the two incisions on the right side, as well as through corresponding incisions on the left side. The enlargement, however, was solid throughout. The child died 12 hours afterwards unrelieved of his symptoms.

The clinical history and subsequent course of the child's illness suggested the possibility of the rapid enlargement of the liver being of an inflammatory nature. The exploration of the liver at the time of operation, however, seemed to point to the condition being one of a rapidly growing neoplasm.

The post-mortem examination was conducted 20 hours after death. The body was that of a well-nourished male infant in which no rigor mortis was present. A trace of post-mortem lividity was evident over the dependent parts of the trunk and limbs. The abdomen was very much distended. The subcutaneous fat was normal in amount and appearance. On opening the abdomen a large mass, evidently the liver very much enlarged, was seen occupying the greater part of the abdominal cavity; it extended for five and a half inches below the tip of the xiphoid cartilage, reaching to within half an inch of the upper border of the symphysis pubis. In the right mammillary line it extended for six inches below the costal margin. The notch between the two lobes was situated in the left mammillary line. The spleen was not visible. The thoracic cavity was encroached upon, the upper limit of the diaphragm reaching to the fourth interspace in the right lateral sternal line. The serous covering over the anterior aspect of the right lobe of the liver was ruptured transversely in two places. The organ had a mottled appearance; dark livid coloured areas with darker points throughout were seen. These were of varying size and were mostly confluent. Where these areas were discrete they were seen to be separated by zones of yellow coloured tissue which possessed the characteristic appearance of liver substance which had undergone an advanced fatty change. On removing the organ it was found to have a uniform firm consistence and the upper surface of the right lobe presented an area irregular in outline and of a yellow colour similar to that described above.

On section the organ was found to be of a firm fleshy consistence. On examination the mottled appearance apparent on the surface was found to be explained by the presence of numerous nodules varying in size from that of a shilling to that of a crown piece. These possessed a central darker area of soft consistence which appeared to be due to hæmorrhage, and outside this a peripheral border of a slate grey colour with numerous red vascular points throughout it. The amount of liver substance recognisable on section was scanty, and this was evidently undergoing a fatty change and was being invaded and compressed by the surrounding nodules which were confluent in the greater part of the organ. The gall-bladder contained thin fluid green bile and the larger biliary passages showed no evidence of disease.

The thoracic viscera were found on examination to be healthy. The spleen was of normal size, structure, and appearance. The kidneys, except for the presence of some cloudy swelling of the tubules, appeared healthy. The pancreas and remaining abdominal and pelvic organs showed no evidence of disease. Examination of the cranium showed at the left inferior extremity of the anterior fontanelle a small nodule of the size of a pea situated in the diploë. The outer table of the skull was thinned over it, the inner table being also eroded considerably but not perforated. The contents of this cavity were of an opaque white colour and of a cheesy consistence. There was a slight increase of fluid in the subarachnoid space. The brain showed no evidence of disease on dissection. The lymphatic glands and bone marrow showed also no evidence of disease. At the conclusion of the post-mortem examination it appeared that the case was one of primary sarcoma of the liver of extremely rapid growth, with possibly a secondary focus of disease in the diploë of the skull.

Microscopical examination showed the structure of the liver to be entirely absent throughout the greater number of the portions of that organ examined. The nodules of apparent new growth were seen to possess a stroma of delicate blood-vessels and fibrous tissue, with here and there a degenerating liver cell present and proliferating bile capillaries. In the spaces formed by the stroma numerous small cells were present. These were irregular in outline, being usually somewhat spherical and possessed a large deeply staining nucleus which occupied the greater part of the cell, the membrane of which could be made out only faintly. Between the cells a delicate fibrillary substance was apparent. In the centre of the space it was as a rule customary to find numerous red blood corpuscles with an occasional polymorphonuclear leucocyte and lymphocyte lying free. At certain areas hæmorrhages larger in size could also be seen. Evidence of active cell division was also very apparent, many tumour cells being seen in various stages of mitosis. No abnormal variety of cell division could be

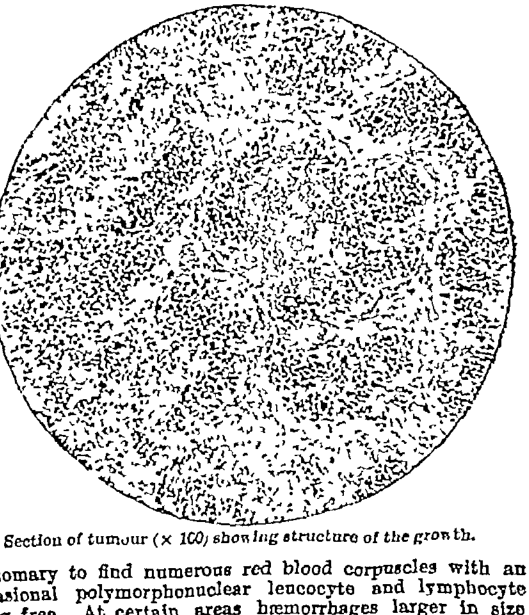
Fig. 2.



Section of tumour (× 100) showing structure of the growth.

detected. At the outer margin of the nodules the cells of neoplasm extended by direct intercellular spread between the surrounding liver cells, the majority of which showed very advanced fatty infiltration and degeneration.

A microscopical examination of the other organs showed nothing especially noteworthy except in the case of the kidney, where the convoluted tubules and the ascending limbs of Henle showed cloudy swelling of their parenchyma. The glomeruli were swollen and contained a recent fibrinous exudate. Swelling of the endothelial lining of Bowman's capsule and an increase in the number of nuclei of the glomerular tufts were also apparent. The microscopical examination of the minute pea-like nodule in the diploë showed it to consist of cells which from their structure and arrangement indicated a chronic inflammatory focus with commencing caseation in its centre, such as would be explained by the effect of tuberculous disease. The microscopical examination of the liver confirmed the diagnosis made at the post-mortem examination of primary sarcoma.

The extreme rapidity of the growth of the neoplasm had been responsible for the retention of many of the interlobular septa and the formation of the stroma described thereby. The hæmorrhage present in the majority of these alveolar spaces is readily capable of explanation on the same ground. It is of interest that, despite the extreme rapidity of growth and the presence of many tumour cells inside blood capillaries in the liver, no secondary metastatic foci could be detected on careful examination by the naked eye and microscope. Whether the changes present in the kidneys indicative of a recent acute toxic absorption are to be explained merely as the result of a terminal infection or are due directly to the products of the neoplasm we do not at present intend to discuss. The appearance of the cells forming the tumour suggested that they were derived from connective tissue and their point of origin had been intralobular, the tumour being thus a true sarcoma and not, as de Haan has suggested, an endothelioma.

The points of interest in this case deserving special note are as follows. The occurrence of a primary round-celled sarcoma of the liver in a child aged four months. The rapid enlargement of the organ, as shown by an increase in the abdominal circumference at the umbilicus—an increase of 4½ centimetres taking place in three days. No associated emaciation, diarrhœa, or vomiting. A marked degree of infiltration of the whole organ by the neoplasm, the few liver cells which remained being in an extreme degree of degeneration. Jaundice and ascites were entirely absent. The late appearance of the clinical symptoms with such gross pathological changes is of interest.

So far as we have been able to ascertain only two recorded cases exist of this condition in children younger than the patient in the present case—namely, those of Heaton and Hewlett, whose patients were aged eight weeks and 14 weeks respectively. The clinical characteristics of these correspond very largely with the present case—namely, rapid enlargement of the liver associated with no other signs or symptoms. Necropsy in both cases revealed diffuse infiltrating sarcoma of the organ. Another case has been recorded by Lendrop, in which the child was four months old. It was also characterised by rapid development of abdominal swelling due to enlargement of the liver, which post mortem was found to have the appearance and structure very similar to that recorded by us. In his case, like the present one, the abdominal enlargement took place with special rapidity in the last two weeks of life.

Another case has been recorded with great accuracy and detail by de Haan. The age of the child was, like that recorded by us, four months. The clinical signs and symptoms were almost identical with those of the present case, the child being admitted with marked abdominal swelling. The liver could be palpated with ease, the lower border extending to the umbilicus. Extreme rapidity of growth took place after the child's admission to hospital so that the enlargement extended into the right iliac fossa in a fortnight. During this period, also, pressure symptoms on the diaphragm and thoracic viscera supervened. Exploration of the liver was carried out as in our own case, in the supposition that the enlargement might be due to the presence of an acute inflammatory condition. The child died four days after operation, the post-mortem examination revealing a diffuse neoplasm of the liver with no secondary deposits throughout the body. Microscopical examination showed numerous hæmorrhages, large thin-walled blood-vessels supported by connective tissue forming spaces filled by tumour cells, which he believed to be of endothelial or connective tissue origin.

The other cases, recorded by Bossowski, Tooth, Pert, Dudgeon, and others, occurred in older patients. The clinical characteristics of these correspond closely with those already referred to in the rapid increase in the size of the growth. Ascites, however, was present in one case, while a trace of jaundice was present in another. In only five of these recorded cases was, as far as can be ascertained from the literature, the lesion entirely confined to the liver.

The investigation of this case seems to show that from the clinical standpoint primary sarcoma of the liver in children, although of rare occurrence, presents definite characteristics, which, although simulating an acute infective condition of that organ, are sufficiently distinctive to warrant a diagnosis of a malignant condition being made.

Our thanks are due to Dr. Burn-Murdoch, senior physician to the hospital, for permission to publish this case, also to Dr. R. J. Mackessack, resident physician, for the photograph taken at the post-mortem examination.

NOTE ON THE LIFE CYCLE OF THE PARASITE OF SLEEPING SICKNESS.

BY J. E. SALVIN-MOORE, A.R.C.S., F.L.S.,
PROFESSOR OF EXPERIMENTAL AND PATHOLOGICAL CYTOLOGY, LIVERPOOL;

AND

ANTON BREINL, M.U.DR. PRAG.,
ASSISTANT LECTURER, RUNCORN RESEARCH LABORATORIES, LIVERPOOL.

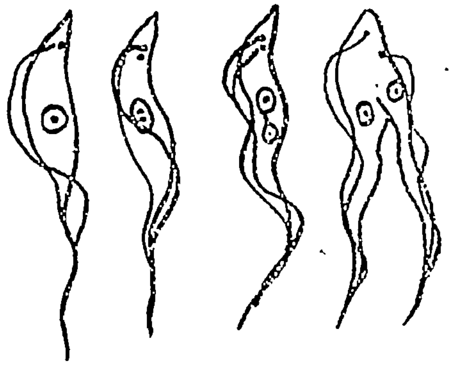
(*From the Cytological and Runcorn Research Laboratories, University of Liverpool.*)

THE observations upon the life-history of trypanosomes to which we desire to call attention in this preliminary note relate chiefly to *Trypanosoma gambiense*. But in order to bring them into their true perspective it is desirable to refer briefly to certain facts already more or less familiar in relation to several other forms. In the case of dourine it is known that the disease can be transmitted directly from animal to animal, contact in this case being the normal mode of transmission. It is clear, therefore, that the life-history of any particular trypanosome need not be necessarily complicated by any transmission through two or more different hosts. The observations of Bruce seem to show that in the case of *Trypanosoma brucei* infected flies cease to be able to infect after 48 hours and it consequently follows that in this instance it is at least possible that transmission is only effected directly as in an ordinary inoculation experiment. *Trypanosoma gambiense* can be transferred directly from animal to animal for many years, the strain utilised in the present work having been propagated artificially for two and a half years. Consequently, if the sexual stage exists in the body of some other host, this stage can be altogether dispensed with for a countless number of generations.

In rats infected with *Trypanosoma gambiense* the disease runs a fluctuating course with respect to the number of parasites to be found upon examination of the peripheral blood. During its course there are a succession of periods when no trypanosomes are to be found in the blood at all. If the blood of rats infected with *Trypanosoma lewisi* be filtered through a Berkefeld filter it has been found to be capable of infecting other rats into which it is injected; though not conclusive in itself, this last observation directly suggests the presence in the infected animals of some minute form of the parasite not hitherto elucidated. During the phases of the infection of rats with *Trypanosoma gambiense* when the number of the parasites is *rising* in the peripheral blood we have encountered only amitotic division of the macro- and micro-nuclei, this process being accompanied by longitudinal fission of the animals. The double and unequal individuals produced, although often at first sight suggesting conjugation, we find to be much more readily explained as stages in the simple process of bipartition, no nuclear changes being seen at all suggesting conjugation as it appears in other protozoa.

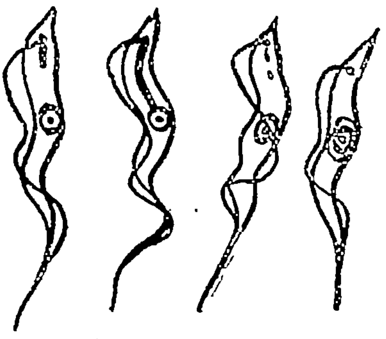
In the case of *Trypanosoma gambiense* we are unable to distinguish any marked dimorphism—the so called males and females of many authors, Prowazik, Minchin, and others, appearing to be arbitrarily chosen extremes in a continuous series of dimensions. As the increase in the number of trypanosomes in the blood proceeds towards any particular maximum we have encountered no other phenomena than that of fission worth recording. At the height of the maximum, on the other hand, numbers (from 5 to 20 per cent.) of trypanosomes may be found wherein a thick stainable band may be seen growing out from the micro-nucleus and extending through the animal's body towards the nucleus. It is at least twice as thick as, and quite distinct from, the stainable margin of the undulating membrane. This band extends backwards until it reaches or even passes beyond the nucleus. In some cases it enters directly into contact with the nucleus. In other cases it reaches the nucleus only indirectly, after passing round one or other side of this body. At this stage of the increase of the parasites in the peripheral blood the nucleus and the micro-nucleus thus become connected; at a subsequent period the connecting band disappears.

FIG. 1.



Stages in the growth and division of *Trypanosoma gambiense.*

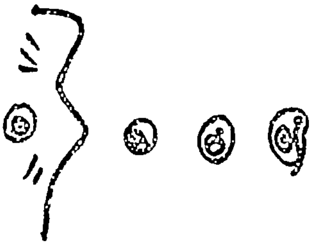
FIG. 2.



Stages in the formation of the "black line" and the "resistant body."

At the time the number of parasites in the blood is falling rapidly another series of phenomena may be encountered in the lungs, spleen, and bone marrow. Here we find trypanosomes in which the nuclei are surrounded by a clear space with a distinct margin encircling the nucleus. Along with these we find in the bone marrow and the spleen numbers of forms in which the body of the trypanosome has disintegrated and the flagellum, together with the remains of the micro-nucleus, is detached. The nucleus in these stages, together with the surrounding hyaline substance, however, remains intact. During the absence of the trypanosomes in the blood these bodies, which we term "resistant forms," undergo no further change. They undoubtedly correspond to the bodies figured by Plimmer and Bradford and erroneously regarded by them as the nuclei of a plasmodium. So, also, they equally unquestionably represent the so-called "free nuclei" described by Holmes[1] and apparently correctly regarded by him as a stage in the development of *Trypanosoma evansi.* During the negative period of the infection they appear to decrease in size, but at the time of the reappearance of the trypanosomes in the blood they are seen, however, to have grown considerably. At this period the nucleus of each resistant form buds off a small, micro-nuclear granule and from this at a later stage there grows out a flagellum.

FIG. 3.



Development of the "resistant body."

It appears, then, that from the spore-like resistant bodies, produced after the connexion of the macro- and micro-nuclei, small trypanosomes are formed directly and thus the life cycle begins over again. Starting from the resistant form the micro-nucleus originates from the macro-nucleus, and in the subsequent division (whereby both kinds of nuclei are indefinitely multiplied) there is a process which may be analogous to the separation of two kinds of nuclei destined to conjugate. A pair of such differentiated nuclei is retained in each trypanosome and unites during the period when the number of parasites in the blood is at a maximum. Viewed in this way the formation of the stainable band and the ensuing union of the substance of the macro- and micro-nuclei may correspond to a sexual act. In the parasite of sleeping sickness we have a life cycle which appears to be complete within the body of one animal just as in the instance of dourine. In this way it appears to be suggested that contagion may be only effected by a mechanical transference of blood in accordance with the results of Bruce in relation to *Trypanosoma brucei.*

Finally, we find when rats infected with *Trypanosoma gambiense* are treated with atoxyl that although large numbers of the parasites are rapidly killed, some become rounded, form a distinct membrane, throw off the flagellum, and apparently remain unchanged for a prolonged period.

It will be observed that the present observations upon *Trypanosoma gambiense* open up a wide field for further inquiry; but it should be pointed out that for these studies we have found it necessary to depart from the usual method of making dry preparations, and to utilise a mode of procedure whereby blood films, or "organ-smears," are fixed wet and afterwards stained and mounted in the usual manner.

The figures are from specimens fixed in Flemming's fluid and stained with a modification of the ordinary iron-alum hæmatoxylin, or with a combination of two basic stains.

ON THE EFFECT OF THE EXPOSURE TO TOBACCO SMOKE ON THE GROWTH OF PATHOGENIC MICRO-ORGANISMS.

BY MILES B. ARNOLD, M.D. VICT., D.P.H. CAMB.,
SENIOR ASSISTANT MEDICAL OFFICER, MONSALL FEVER HOSPITAL, MANCHESTER.

THE belief that smoking decreases the risk of contracting the infectious diseases is so widely held that all whose work provides opportunity for meeting men exposed to the danger must have noted the hurried lighting of a pipe or cigar immediately after any such exposure. One is appealed to frequently to give an opinion as to the efficiency of the procedure and as some references in medical literature gave vague support to the belief, I began a series of experiments to determine the bactericidal power of tobacco smoke. I am indebted to Professor S. Delépine for the helpful suggestion that it would be well to compare the effect of smoke from some dried vegetable matter not containing similar toxic organic bodies; hay was selected for the control experiments. I may say at once that the smoke from both tobacco and hay was found to be bactericidal. The apparatus used will be readily understood from the illustration. A is a large pipe bowl. B is a sloped nutrient agar tube with a side tube let in and during the experiment a perforated rubber bung with glass tube replacing the cotton-wool plug. After the experiment the rubber bung and the rubber tube shown attached to the side tube were removed and replaced by sterile cotton-wool plugs. C is a large glass syringe used to draw air through the apparatus.

---

[1] Journal of Comparative Pathology and Therapeutics, 1904, p. 213.

The method of experiment was as follows. A tube such as shown in the illustration and a plain nutrient agar tube as a control were inoculated from the same pure culture. A having been filled with the substance to be burned, the rubber tubes were connected and a light applied to A. The syringe was then worked and smoke came readily through the tube B. A timed exposure, five minutes, of the inoculated tube to the smoke having been given, the rubber tubes were disconnected, cotton-wool plugs replacing them, and the tube B and the inoculated control tube were placed in the incubator and observed.

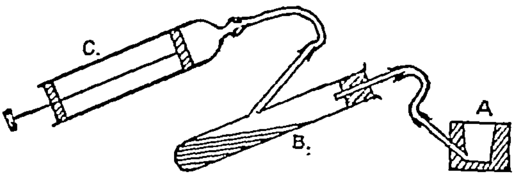


Diagram of arrangement for aspirating tobacco smoke over a culture.

There may seem at first sight considerable danger of air contamination. This, as a matter of fact, only occurred once. The organisms tested were: bacillus diphtheriæ, bacillus typhosus, bacillus coli communis, staphylococcus pyogenes aureus, and on one occasion a streptococcus isolated from the blood of a case of scarlet fever. All the experiments were repeated five times, with the exception of those on the streptococcus. The tobaccos used were of different kinds from a cheap navy cut to one of the more expensive mixtures. No difference was observed in their action. They were well dried and about one-twelfth of an ounce was used for each tube. The exposure of each tube was five minutes. All the control tubes grew typically and when growth occurred in the smoked tubes films were made and the organism examined to eliminate error from contamination.

The results observed in the smoked tubes may be summarised as follows:—1. The bacillus of diphtheria was always markedly affected. Sometimes it failed to grow at all, but in some cases there was a slight growth. This was the case both with the tubes smoked from tobacco and with those smoked from hay. 2. The typhoid bacillus grew but very much less than in the control tubes. In some instances there was no macroscopic growth at the end of 24 hours. 3. The bacillus coli communis grew fairly well though distinctly less than the control tubes. 4. The staphylococcus pyogenes aureus was hardly affected except in one experiment with smoke from hay. 5. In the experiment made with a streptococcus no growth took place in the smoked tubes. I have therefore come to the conclusion that tobacco smoke as drawn into the mouth is very probably detrimental to the growth of some pathogenic organisms, but not more, indeed rather less so, than smoke from other sources. I should like to make it clear that I state this simply as a fact observed and not as an argument in favour of the use of tobacco.

The following paragraph from Rideal's book[1] on disinfection refers to experiments on the subject. "It is recorded that Tessinari found that tobacco smoke, on being passed through tubes containing a nutrient gelatine and pathogenic germs for from 10 to 30 minutes destroyed the bacilli of Asiatic cholera and of pneumonia. Tobacco smoke passed through water killed the yellow bacillus." Trillat[2] has made a very large number of experiments on the disinfecting power of various smokes, including that of tobacco. His work has been chiefly chemical. He attributes the action to formaldehyde, the smoke from 100 grammes of tobacco yielding 0·063 gramme of formaldehyde. Cigars gave a much higher result—0·118 gramme from the 100 grammes. I have recently come across an interesting pamphlet[3] written 50 years ago, the writer of which writes enthusiastically in favour of tobacco, and in his introduction asks: "Shall we seek and ultimately find an explanation in the undoubted existence of countless millions of microscopic animalculæ which surround and penetrate us on all sides—agents of disease, whose more visible congeners we so easily exterminate for a time by the aid of fuming narcotics, especially tobacco?" The introduction to the pamphlet is a very spirited reply to a paper condemning the use of tobacco by Mr. Solly in THE LANCET of Feb. 10th, 1857.

I am much indebted to Professor Delépine for his suggestion, and to Dr. A. Knyvett Gordon, medical superintendent of Monsall Hospital, Manchester, for permission to use the hospital laboratory and publish the results.

Manchester.

THE USE OF ANIMAL BLOOD SERUM IN SURGERY: PRELIMINARY NOTES.

BY W. STUART-LOW, F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, AND JOINT TEACHER OF PRACTICAL OTOLOGY, POLYCLINIC COLLEGE.

FOR some time I have been employing a method of dressing wounds that has long passed from favour with surgeons—viz., the use of oiled silk as a dressing coming into intimate contact with the healing surface. If the healing process is hanging fire and the wound is ready to heal but will not, either from some surface sepsis or from mere sluggishness of circulation and healing action, it is remarkable how soon with the immediate oiled-silk dressing improvement begins. I have watched this over and over again. In one of the first cases in which I resorted to the oiled-silk dressing the change for the better was very marked indeed. A young man on whom I had performed an extensive operation for acute mastoiditis, opening a large Bezold's abscess low down in the neck, made a very satisfactory recovery up to a certain point. The mastoid bone had been nearly completely ablated, with the result that at the end of three weeks a very large and deep excavation remained, which stubbornly refused to heal over, and where healing did occur it rapidly gave way again every few days. On applying the oiled-silk dressing the parts rapidly came under healing action, with a result that in a week what had been quite recalcitrant to every agent used was completely healed over with sound cuticle.

A number of such cases impressed me very much. In endeavouring to explain the reason why I came to the conclusion that it must be the blood serum (or lymph) and the assistance given to the surface circulation. Dry dressing in contact with a healing part absorbs the normally exuding serum and becomes adherent to the growing tissues, and thus blocks the exudation and therefore the surface circulation and dries the granulations. The oiled silk does not, but allows a constant exudation of serum from the surface vessels, and being itself non-absorbent keeps the wound always bathed in serum. Such a surface serous bath prevents sepsis and aids superficial circulation in the healing region. In the one case the growing tissues are continuously having the blood serum sucked from their surface, whereas in the other case this is not so, there being always a layer, even though sometimes only a thin one, of blood serum maintained upon the healing area. It is proverbial in surgery that too dry wounds do not mend well and this, I venture to think, is the explanation. One naturally asks why such a dressing as an oiled-silk protective ever went out of favour but the reason is not far to seek. It cannot stand sterilisation by boiling or immersion in spirituous or strong antiseptic solutions, and it therefore soon fell under the ban of most surgeons. I simply wash the protective in sterilised water or in boric solution before applying it over the wound; it is not necessary to do more, because the blood serum and lymph that rapidly collect under it keep the wound sufficiently aseptic.

---

[1] Disinfection and the Preservation of Food, by S. Rideal, 1903, p. 255.

[2] Annales [illegible] t Pasteur, 1905, vol. xix., p. 722.

[3] Tobacco: Its History, Cultivation, Manufacture, and Adulteration, by Andrew Steinmetz, 1857.

Having observed and reflected upon these facts about wounds and studied the theories on opsonins and the wonderful practical application of them by Sir Almroth E. Wright, I argued thus. If so much depends upon the blood serum, why not try to increase the amount of it in and about healing parts by employing animal blood serum as the fluid with which to sluice, to irrigate, and to dress wounds? Pure healthy blood serum would seem to be ideal for this purpose, as it is essentially non-irritating and, in fact, has a soothing, cooling effect on injured parts. It is alkaline in reaction and from albuminous matters held in solution has a slight viscosity that gives it to a considerable degree air-excluding, and to a lesser degree adhesive, covering and protective properties which are all conducive to healing. It is now admitted by all pathologists, too, that normal blood serum possesses restraining influences on bacterial growth because of the antibodies it contains, and Sir A. E. Wright's researches have proved that blood serum also contains those substances which have the marvellous power of preparing micro-organisms for ingestion by the white blood corpuscles—viz., opsonins.

Here, then, in normal blood serum we have, I think, the best substance and the natural substance for perfect and rapid repair of wounds. The chief objection to even mild antiseptics has ever been that they have always some degree of irritative and devitalising effect on the tissues and there is no certainty that micro-organisms are destroyed by their action. Indeed, there is little doubt but that the beneficial action of some antiseptics, and probably also of some aseptics, such as normal saline solution, consists in the fact that they do irritate the tissue and in this way ensure an increased outflow of serous fluid and stimulate the circulation about the healing parts. To supply the blood serum without applying the irritant ought to be better. But the researches of Sargent and Dudgeon have shown that wounds healing by first intention are not bacteria free, and it is quite possible that certain micro-organisms may be necessary to perfect union. Therefore, such a substance as blood serum, which inhibits but does not arrest all bacterial growth, would seem to be the most suitable.

For the purpose of putting these views to the test I obtained a quantity of fresh blood from the butcher, which had been poured directly from the incised aorta of a young, fat, healthy, two-year-old sheep into sterilised vessels. The blood was kept in air-tight glass jars for two days and, coagulation having taken place, the blood serum was then drawn off and secured in smaller sterilised glass air-tight jars. I am still doubtful how long to leave the serum in contact with the blood-clot, but the longer they remain together the darker the serum becomes, which is doubtless due to the hæmolytic action of the serum on the red blood corpuscles. I think what I have found to be the best serum for my purpose has been that which I syphoned away from the clearer collection at the top of a tall cylindrical vessel. I now have a supply of fresh blood every three days, and remove the serum every other day into the smaller, more portable, glass jars which I carry with me to operations. If the success of others employing blood serum is as great as in the cases in which I have employed it, it may be that in the future normal serum may prove as useful and be as commonly placed ready to hand in our operating theatres as normal saline solution is at present.

It is mostly in ear cases that I have used blood serum. It seems particularly well suited for such, as there is so much bone excavation which leaves a dry as distinguished from a weeping wound. Desiccation in a wound is generally inimical to ready repair and this has been successfully avoided when blood-serum dressing has been employed. In every instance the soft structure healed by first intention. There was a singular absence of pain all through the time of recovery and the epidermisation in the ear cases seemed to proceed more quickly than usual.

Welbeck-street, W.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—The annual general meeting of this association will be held in the rooms of the Royal Medical and Chirurgical Society, 20, Hanover-square, London, W., on Tuesday, May 7th, at 4 P.M. Tea and coffee will be provided at 4.30 P.M. At 5 P.M. a meeting will be held, open to all medical practitioners and students on presentation of visiting card, at which Professor G. Sims Woodhead, president of the association, will give an address on the Medical Justification of Total Abstinence.

THE BALNEOLOGICAL TREATMENT OF URINARY DISEASES.

By DR. OSCAR KRAUS.

(Concluded from p. 1153.)

I WILL now deal with the question, when can Carlsbad treatment promise a success and when ought surgery to assert its rights. The answer is not difficult. The progress in Roentgen technique has now made it generally possible, except in cases of very obese persons, to locate even small stones, especially if a compression-cylinder be used. The largest calculi that we ever saw passed through the natural passages in an attack of renal colic were of about the size of an almond (they are still in our possession). These were passed by a woman. Whether still larger stones have by any means a favourable chance of traversing the urinary passages without stoppage is questionable. At any rate, in the case of a man we should consider an operation indicated as soon as this size seems from the reduced radiogram to be considerably exceeded, or if the general symptom-complex seems to demand removal of the stone. If the Roentgen examination be negative, or if the calculi be no larger than the size given above, it is proper to try the Carlsbad method. This treatment is by all means indicated *after* an operative procedure, in order to flush out the smallest particles, which can never be completely removed at a nephrotomy—particles like the gall-sand at a gall-bladder operation. The treatment is indicated after operation for the additional purpose of combating the catarrh of the urinary passages, especially that of the renal pelvis, and thus to guard against a new stone formation around the secreted mucus as a nucleus. Moreover, the influence of the basic water in the urinary acidity, when the case is of the acid variety, is to be desired. But even where this factor is not present, as in cystin stones, we may often note the useful effect of the mechanical washing-out of the particles. I well remember a patient several years ago on whom Zuckerkandl had done a nephrotomy; she came from the sanatorium directly to Carlsbad and there passed large quantities of cystin sand and made a quick recovery.

We now come to the discussion of a class of patients who are continually being sent to Carlsbad—namely, those with stone in the bladder. Such patients ought to be sent to a mineral spring *after* a lithotripsy or a section has been already performed, and as soon after as they can be moved. Nowhere else will they so quickly lose the cystitis which is usually present, nowhere will they recover so rapidly, as under the hygienic *régime* and in the open-air treatment of a watering-place of this kind. The stimulation of urinary secretion and the regulation of the digestion never work so quickly and so beneficently as in these cases. Such patients are the most grateful that we see at Carlsbad, whether the concretion was uratic or phosphatic. I have in every such case observed a very considerable elimination of sand—urate, phosphate, oxalate, or even cystin sand. I must emphasise again that this is not only and not always a case of purely chemical processes but of mechanical and biological as well, processes which, of course, I need not here discuss. I can say but one thing with certainty: urates are not "dissolved" by Carlsbad water. Small stones are swept out and the formation of new calculi prevented by the increase in metabolism. Large stones must be removed surgically, whether from the renal pelvis or from the bladder. Patients should be informed on this point, so that they will not demand the impossible. Occasionally, patients come to Carlsbad without the advice of a physician in the hope of avoiding a lithotripsy. That is, of course, foolish. The stones, as we have said, cannot be dissolved. But when the stones are moveable, such a one may become impacted as a result of the long walks or of the railway journey itself. The same is true of kidney stones. I shall never forget a case of a young man who was sent to Carlsbad a few days after an attack of renal colic and before the expulsion of the stone. An hour after the departure from Vienna the stone left the bladder, but not being able to pass the orifice of the urethra it remained there until evening. I need not dilate on the sufferings of the poor man during the eight-hour journey. On his arrival I had to do a meatotomy in order to extract the almost almond-sized concretion with the forceps. Therefore one should always await the passage of the stone after an attack of colic before a journey is allowed.

Here also belongs the case of an old man who came to Carlsbad with a calculous cysto-pyelitis. He was very wretched and debilitated, with persisting fever and hæmorrhages, and his progress toward recovery was very slow. When the cystitis had somewhat improved he passed, as he had repeatedly done before, 15 or 20 calculi, either at home or in the course of walks, and quite without difficulty or pain. These were characteristic stones from the pelvis, either perfectly round or slightly faceted. In spite of this his slight symptoms, chiefly some strangury and frequency of micturition, would not yield. Cystoscopy showed the presence of a small stone in the bladder, which I removed by means of the aspirator. It would be worth while to recommend that after every attack of renal colic the patient should be cystoscoped as soon as the slightest indication arouses the suspicion that the stone was not passed. It need not be pointed out how well these small concretions are qualified to form the nucleus of a vesical stone, particularly when, as in this case, the folds of a *vessie à porte-feuille* tend to imprison the stone. Occasionally patients with a stone are sent to a watering-place to be healed of their cystitis before operation. That is, of course, so much pains wasted, for as long as the stone is there the *fons et origo mali* is not removed and the bladder cannot be healed.[1] After operation, however, the case is quite different. As soon as patients can be moved they ought to "flush themselves out" diligently and lose their cystitis if such be present. By stimulating the peristalsis and loosening the bowels the circulatory disturbances in the pelvis are relieved; by increasing diaphoresis (with baths, &c.) and diuresis the toxins are eliminated and "urinary" fever is most successfully combated.

In this connexion we come to a condition about which a few remarks are called for. This is the so-called *uric acid diathesis*—an affection which seems to have increased prodigiously in recent years. Exactly what, then, is this uric acid diathesis? I have taken the trouble to make inquiries on this point among a number of excellent physicians and surgeons for the simple reason that I have myself never seen a morbid type which would answer to this title, and I saw from their answers that they also were rather at a loss to make a definite statement. We often see the report in our uranalyses of a "heavy uric acid sediment" or "increased uric acid in the sediment," and this in the case of a patient who has nothing wrong with him but for a few more or less imaginary complaints. The conditions governing the solubility or insolubility of certain normal urinary constituents, such as the urates, the phosphates, uric acid, are not known certainly. Why is uric acid sometimes precipitated from solutions and sometimes not? And why the phosphates? How does it happen in one and the same individual that the taking of carbonated drinks at one time causes a cloudy or milky urine and at other times not? We are only too far as yet from understanding these most intimate metabolic processes, processes which are certainly not purely or wholly brought about by chemical conditions. To be honest with ourselves we must admit that we know little more about the conditions under which uric acid is precipitated from the urine than that it happens regularly in the cold and also in circumstances which we are not able to explain satisfactorily. On this point the most trustworthy investigators are united; reference may be made among others to a piece of work by Ritter.[2] Uric acid precipitates for unknown reasons from the urine of sufferers from arthritis or other diseases, but it also often does the same in that of healthy individuals, without any increase in the total acidity or in the content of uric acid. Moreover, the uric acid often precipitates without our being in a position even to draw any conclusions from the fact. We know, in short, as little about this as we do about oxaluria and phosphaturia or about the alternation of oxaluria with uraturia or of phosphaturia with uraturia in the same person. All explanations which have been offered are unable to stand the test of criticism. We do know, however, that it is impossible to speak of an absolute or even of a relative increase in uric acid excretion without a complete examination into the metabolism based on comparative data for the same individual, and especially without taking account of the diet. To speak of "increased uric acid" in the sediment is nonsensical because we do not know the conditions of uric acid precipitation in health, or, in other words, what the "normal" amount of uric acid in the sediment is. However, what the apothecary or chemist reports as uric acid is usually amorphous sodium urate, often mixed with a few small whetstone-shaped uric-acid crystals. Practical experience has taught us that this appearance has no significance whatever, either clinically or pathologically; on this point I know that I am in agreement with clinicians of note. One of these, Dunin, to whom we owe, among many other excellent researches, that paper on the relation between habitual constipation and neurasthenia, made this very question the subject of an investigation and comes to conclusions similar to ours. Unfortunately, the paper was written in Polish and is thus only accessible in reviews.[3] The principal theses are the following: 1. The existence of an arthritic diathesis after the meaning of the French authors must be emphatically denied. 2. It is not proved that metabolism is at all slowed in diseases of this category. 3. From the superficial uranalyses as usually made in practice far-reaching conclusions, and especially diagnoses of "arthritism," are quite untrustworthy. 4. The supposition of a uric acid diathesis seems, in view of present knowledge, to be unwarrantable. 5. The significance of uric acid in the etiology of arthritis and of renal calculus is to be regarded at present as unknown.[4] Among the many cases which we have been able to follow with care during the last 18 years, we have found none where increased uric acid in the sediment had any meaning. On the other hand, we have again and again found for years before the appearance of calculi those characteristic large dumb-bells and the pointed forms of uric acid crystals to which Ultzmann in his lectures attributed a premonitory significance. We have always remembered particularly two cases where we achieved some renown as a prophet by cherishing this remark of Ultzmann.[5] But these are only the premonitory signs of gravel.

There are no objections to be made on principle to the introduction of synonymous but relevant new terms, although the clearness of the conception rarely gains thereby. We know that the coronary asthma of to-day, the stenocardial attack of yesterday, and the angina pectoris of our fathers are one and the same. And so I have myself here and there made use of the expression "uric-acid diathesis" because it was the fashion. But I should like to propose dropping it for good and all, as we have dropped the "herpetic diathesis." They simply do not exist. But even if we do not recognise a uric-acid diathesis we do know the arthritis urica and gravel. Both lead to a deposition of urates in the organism. I described a symptom ten years ago in a communication to the Paris Académie de Médecine,[6] which I called "pollakiuria urica," a symptom which in itself may constitute a complete morbid condition. At that time I referred to the fact that the majority of persons who show crystallised uric acid in their sediments are not sufferers from pollakiuria, but that in certain cases where changes exist in the neck of the bladder region or the prostatic urethra, themselves incapable of causing a pollakiuria, the paroxysmal excretion of large amounts of uric acid, especially in the form of pointed crystals, can produce a pollakiuria of high grade. Such paroxysms of uric acid excretion are not rarely seen in patients with arthritis, and if this excretion can be made to disappear by the administration of alkalies and other proper treatment, as, for instance, at Carlsbad, this distressing symptom will disappear as well.

---

[1] Latterly, it has become rather the fashion to undertake stone-crushing operations at watering places. I am of the opinion that this is not advisable, since such a patient should not be asked to take a long journey. Nowadays, when surgical practice is no longer a prerogative of the few elect but has become fairly general there can be found in every large city, and in many of moderate size, men who can perform such an operation faultlessly and under the best of external conditions, in good nursing homes. The patients need not be carried far, and we do not see any reason why patients should need to be in a hospital or doctor's home at a watering-place, if they can get no benefit from balneological treatment, even of the best. Allow me to speak at this point of a curious "fashion" which has lately appeared among patients with concretions—namely, that of going every year or two years to a water cure "to have their stone, which has formed again, crushed." There are, as a matter of fact, people whose excretion of urates or phosphates is so rapid that relapses do occur—after a long period, rarely after a short one. But when we hear that certain operators perform crushing operations regularly every year or two for a considerable number of their patients, we are moved to recommend them that they heed Guyon's advice and "carry the crushing to its utmost limits," and further, on no account neglect the "verifying examination" (Clinical Lectures, German edition by Oscar Kraus and Otto Zuckerkandl, vol. iii., pp. 328 and 372). If this were done their cases might show a considerably diminished number of relapses. We know that genito-urinary surgeons of prominence share our view. That it is reasonable is perfectly evident. Only small fragments can go through the aspirator or be spontaneously passed. For this reason the old Bigelow method has been losing favour, because in this the crushing is made of less importance than the evacuation. The surgeon who wishes not to leave fragments behind to cause relapses will crush the stone to the smallest possible atoms. Bladder irrigation and stimulation of diuresis will wash out the last particles, and it is just here Carlsbad may assert her rights in the after-treatment of a litholapaxy.

[4] Cited from Ziegler-Kahlden's Centralblatt, March 28th, 1901.

[5] I have spoken of one of these cases in another publication (Report of the Meeting of the Paris Académie de Médecine and Annales des Maladies des Organes Génito-urinaires: La Pollaquiurie Urique, Nov. 23rd, 1897). This case was one of diabetes. Since my communication before the Académie de Médecine the patient has been obliged to have a small stone crushed. The other case was of a man who had been sent to Carlsbad on account of enlarged liver. I advised a change in his manner of living and threatened him with renal colic and vesical stone. Both made their appearance: first the colic, and two years later I discovered a stone in his bladder myself. In both cases the above-mentioned pointed uric acid crystals had shown themselves for years before. In the first case the etiology of the gravel, as is so unfortunately common, was the diabetes, the nitrogenous diet, and the lack of exercise due to an ankylosis of the hip after a fracture of the neck of the femur.

No less a man than Sir Henry Thompson[7] writes as follows concerning the effect of Carlsbad treatment on uric acid excretion:—

> Now, the principle upon which the waters of the sulphate of soda group, aperient and non-aperient, are beneficial is, that they produce activity in all the digestive functions, stimulating the excretory action of the abdominal organs, so that certain waste matters, which have hitherto been thrown out as uric acid by the kidney, are eliminated in some other form. If, therefore, it is really desirable to recommend resort to a mineral spring as treatment for uric acid deposits, I should prefer Carlsbad, and certainly never send a patient to Vichy, Vals, Evian, or Contrexéville. And when a stout active man, whom it is most desirable to separate from his home engagements and business cares, requires a Carlsbad course, he may often visit the locality with advantage.

In our discussion thus far we have repeatedly touched upon the subject of *cystitis*. It is one of the most gratifying for thermal treatment. Under the influence of the drinking and bathing an acute, non-gonorrhœal cystitis usually recovers quickly without any local treatment. Those forms are especially often seen here which occur in connexion with gravel, apparently due to the insult to the mucous membrane from the uric acid concretions. Such a urine is, as is well known, acid, contains red and white blood corpuscles, pus cells, bladder epithelium in small quantities, and fewer or more of the pointed forms of uric acid crystals. Chronic cystitis with amphoteric or alkaline urine must of course be treated locally. But it is just here, and especially in the more stubborn forms, that the balneological treatment shows its value. I think it will be conceded that usually, in beginning local treatment, a physician cares relatively little for the systemic, that he confines himself to forbidding certain articles of food and drink (alcohol, spiced foods, &c.), and is usually not in a position in the city to prescribe at the same time mineral drinks and therapeutic baths. But it is most of all in connexion with chronic vesical catarrh that the value of this part of the treatment as adjuvant to local measures is under-estimated, as our practice testifies. Here the increase in metabolism performs great services—indeed, it often works miracles almost. Just what we imply by this increase in metabolism we have elsewhere discussed.

We must characterise as categorical and illogical that dogma which is too often voiced, "alkaline urine, *ergo* no alkalies, *ergo* no Carlsbad." The urine is alkaline in the "alkaline cystitis" because it contains pus and is in a state of ammoniacal fermentation. If this pus and fermentation be removed by local and general treatment the alkalinity of the urine disappears *ipso facto*, and, paradoxical as this may seem, an alkaline cystitis never responds so well as under the influence of alkalies, especially those of the sulphate springs; these open all portals for the escape of the toxins of the colon bacillus and the rest. On the principle "when all else has failed, try Carlsbad" a great number of old protracted cases of cystitis are directed to Carlsbad. The people in question are the most grateful of our patients. In this class are those forms of old chronic cystitis which need constant or very protracted treatment, which are complicated with prostatic disease of high grade, strictures, &c., and are accompanied by the remote symptoms of chronic uræmia. The *sonde à demeure* has been recommended for such cases to drain the bladder constantly. I must say that in general I am not an advocate of this method, for the permanent catheter requires the patient to stay in bed, and thus the already insufficient digestion suffers and the recumbent attitude favours hyperæmia of dependent parts, the prostate, the bladder, and the other pelvic organs The inactivity gives the metabolism and so the impulse to recovery another set-back. Here the open-air treatment shows to advantage and we may meet the indications for thorough bladder drainage just as well if we have the patient catheterised for every micturition—i.e., at least four times daily and once or twice at night—of course, with all aseptic precautions—and allow him enough outdoor exercise to stimulate the digestion and to meet the need for fresh air, a need that should not be underrated in such cases. In this way there can be no considerable stagnation of urine and the bladder is washed once or twice daily with boric solution (or with Mühlbrunn or Sprudel water) and silver nitrate injected or instilled as well.[8] The fresh-air treatment is important for these patients, as I have already stated, so also are the baths, the massage, in some cases carefully selected light gymnastics, the *régime*, the stimulation to the digestion, and last, but not least, the flushing out of the urinary passages with sulphated alkaline waters. In the management of chronic diseases and of those of metabolism all possible curative agents must be called upon to enhance the effect of the drinking and bathing treatment.

We cannot refrain at this point from citing a remark by that keen medical thinker, F. A. Hoffmann. He says:[9] "The great value of the Carlsbad treatment, which we are constantly prescribing, is so far from clear scientifically that one would lay himself open to the charge of phantastic theoreticism if one were to say anything definite on the subject." In fact, Carlsbad practice yields results which had better be taken thankfully and without racking the brains over the *cur quo modo*.

Hypertrophy of the prostate is seldom the subject of treatment unless it is associated with obesity, chronic arthritis, or especially with chronic constipation. In the first stage, when periodical feelings of pressure or fulness and the irritation in the rectum are the only complaints, a simple course of drinking and bathing, or of the former alone, will benefit without other adjuncts, without even prostatic massage. Here the case is usually one of paroxysmal congestion of the gland coming on under the influence of stasis in the lower pelvic organs. As soon as order is restored by regulating the digestion the complaints disappear. In such an aseptic case the introduction of an instrument should be avoided. On the other hand, where there is a large quantity of residual urine, where the impediment to the outflow is really considerable, one cannot too industriously drain, wash, and, as Guyon expressed it, "modify" the mucous membrane of the bladder. This is no place for a dissertation on prostatic hypertrophy, but we may say this: that the greatest effort should be made to prolong the first stage, or, in other words, to put a catheter into the patient's hands as late as possible. If the operation is indicated one must not wait until ascending processes have made the prognosis unfavourable. Such processes lead to the signs of chronic uræmia, which we have already fully discussed. All these patients catch cold easily, therefore especial caution must be observed; and since a "cold" is by no means a small matter for people with chronic urinary trouble they should be sent to a watering-place only in a favourable season. In the cold spring of 1905 I had the opportunity of seeing some particularly unpleasant instances of this. I shall always remember one case of an old gentleman with a tremendous enlargement of the stomach, with atony, an old cystitis, and prostatic hypertrophy. The treatment of the last-named was being postponed on account of the wretched general condition. After starting treatment the digestion improved, the stomach-tube, a necessity hitherto, was dispensed with, and the weight increased. Everything looked bright. Then the old man caught cold and the symptoms of acute prostatic congestion came on, with fever, with exacerbation of the cystitis, which, of course, worked back on the gastritis, producing vomiting, singultus, anorexia, and prostration. The clinical picture became so threatening that I felt myself fortunate when the treatment of the bladder, which I then had to begin, had after a few days removed the imminent danger. To such cases the experienced urologist is no stranger.

[6] Session of Nov. 23rd, 1897.

[7] Diseases of the Urinary Organs, eighth edition, 1888.

[8] The irrigations are best performed by means of the irrigator and use may well be made of a two-way tap. I demonstrated an aseptic model of such a tap in February, 1907, before the Gesellschaft der Aerzte in Vienna. It may be obtained of H. Reiner in Vienna.

[9] Von Leyden: Handbuch der Ernährungstherapie, second edition, 1903, p. 481.

This brings us to a class of patients whom Guyon denominated as "faux urinaires," which could be translated as "pseudo-urinary" cases, though the former, like many another French expression, has won its place in our urological nomenclature.[10] Guyon understands by this term "patients with symptoms which are falsely localised by them, and which indicate a really existing disease, even if in another organ (i.e., other than the urinary apparatus)." We might go further and understand a symptom-complex which can mislead not only the patient but the physician, and which may indeed imitate closely an affection of the urinary apparatus, thus leading to failure to supply appropriate treatment for the case. Perhaps one sees more of these in Carlsbad than anywhere else. To give an instance, the chronic dyspepsias with increased frequency of micturition are well known. I may mention here two cases of this type, such as are not particularly common.

A middle-aged gentleman, a professional brother, consulted me for a troublesome pollakiuria combined with pain in the urethra, and especially in the glans. Even the introduction of a Nélaton bougie caused extremely severe pain. The patient thought he had a stone and wished me to sound him. I declined, however, to make this examination, not only on account of the extreme sensitiveness of the urethra, but chiefly because the diagnosis was evident from symptoms. Even such freely explored *viae naturales* as these should not, for mere curiosity, be explored with an instrument. Against my advice, however, the patient, to whom for sufficient reasons I had not told the real diagnosis, had a sound passed by another hand—of course with negative results, for before the examination was made I had told his family that he was suffering from those vesical and urethral crises which were described by Geffrier[11] and Fournier[12] as characteristic of the pre-ataxic stage of tabes dorsalis. In this case the drinking cure and hydriatric procedures had a favourable influence on both the intestinal disturbances which were present and the course of the fundamental trouble. I have seen the patient lately and was astonished at finding how well he was doing.

This case is not exceptional; tabetics have consulted me repeatedly in the earliest stages of their disease, on account of bladder disturbances, and I have always seen good results from the above-mentioned treatment. The good effects of hydriatric procedures in tabes are well known, but I wish to emphasise especially that by means of the drinking cure in addition we may meet the symptomatic indications and influence the intestinal and vesical disturbances.

The second of these "pseudo-urological" cases was the following. A patient was sent to me five years ago with the diagnosis of nephrolithiasis. As a matter of fact, he had passed a number of uratic calculi about a year before after a typical colicky attack. But at the time that I examined him, in spite of intermittent pain in the kidney region, there was neither sand nor gravel in the urine. The type of this pain failed, moreover, to simulate that of a renal colic closely enough to give me any real cause for doubt, and, in fact, on more careful examination I found it to be a case of sciatica and one which cleared up rapidly under the administration of alkalies, massage, and mud baths (it was apparently of the uratic form). The false diagnosis had been made, of course, on the basis of the former attack of renal colic and more particularly because the pain was chiefly in the distribution of the iliac branch of the iliohypogastric nerve—that is, about in the kidney region.

Similar pseudo-renal colics may be imitated as well by chronic constipation, when deposits of hard scybala may be present in the splenic flexure, and more often by spastic constipation involving the descending colon. This frequently causes pain, often rather severe, which may radiate as far as to the right testicle, and is often increased by pressure over the splenic flexure. Appendicular and tubal colics may also be mentioned in this connexion.

There is another class of patients whom I should call "urinaires dissimulés," or concealed urological cases. They form a considerable contingent of the visitors at Carlsbad. These are people who complain of little else than digestive disturbances of various kinds, of constipation, chronic diarrhœa, anorexia, hemicrania, &c., symptoms which in reality are remote manifestations of a local affection of the urinary apparatus—i.e., of a chronic uræmia. In this character appear especially chronic nephritis and prostatic disease. These patients are in a particularly delicate equilibrium as regards health. They know that they "once had a catarrh of the bladder," but that was long ago, and they are used to it. They come to Carlsbad because of poor digestion. They have been advised to "give their bladder a complete rest for a while"—that is, not to have it treated locally! I have elsewhere reported one such case.[13] But the physician is guilty of a serious sin of omission if he does not treat such cases locally and of a disastrously wrong diagnosis if he handles them as stomach or intestinal affections. I will cite here two cases.

The first case was that of a woman who was over 60 years of age and who had from time to time for many years come to Carlsbad on account of cholelithiasis. She had been for some time under treatment by different well-known gynæcologists for a pelvic trouble. She was referred to me by her own Carlsbad physician because she had "suddenly" begun to suffer from strangury. On examination I found a prolapse of the uterus and, as often happens in connexion with it, a prolapse of the anterior vaginal wall and a part of the bladder, so that this pocket-like portion did not empty itself—like the furrows in a prostatic case. In the same way there was here a residual urine amounting to between 50 and 100 cubic centimetres. A chronic cystitis was present which the patient considered of quite trifling importance. A well-known urologist, since then deceased, had directed her to catheterise herself over a hand-mirror and occasionally to irrigate the bladder. She had done so "occasionally" if the cystitis was troubling her. This time the strangury was annoying her unusually because, as she said, she had "turned her stomach by eating bad peas." The bad peas here were a typical urinary fever, with profuse diarrhœa, almost unbearable tenesmus, nausea, &c. Her condition caused considerable anxiety for 24 hours, but finally yielded to rest in bed, great quantities of hot sprudel water, and, for the pollakiuria, cocaine applications to the vulva. As soon as the patient could get up the cystitis was treated with success. The digestive complaints were not mentioned again. A pessary relieved the retention.

The second case was that of a woman from Northern Bohemia. She took to bed immediately on arrival at Carlsbad. She had been ailing for many months and was said to have biliary sand. On entering the room one could make a diagnosis of ammoniacal cystitis by the sense of smell. Also, in this case there was urinary fever; the bladder proved again to be the *porta malorum*, and appropriate local and general treatment resulted in a disappearance of the fever and an increase in the strength. This patient had also, as a matter of fact, an affection of the liver and was jaundiced; but it was impossible to refer all the symptoms, fever, prostration, anorexia, and diarrhœa, to the biliary function. These were all remote symptoms of chronic uræmia. One must not be satisfied to refer all phenomena without afterthought to a disease that is known to exist, otherwise therapeutical signs of omission may be committed with disastrous results.

I have elsewhere called attention to the fact that a pollakiuria in *diabetes* should always arouse suspicion of a non-diabetic cause. When such a patient complains of increased frequency of micturition one should not be satisfied to ascribe it merely to the diabetes and to consider everything thus explained, but should always look for a possible other reason. Almost without exception a complicating affection of the lower urinary passages may be demonstrated, which was the source of the pollakiuria. I am convinced that, although diabetes may cause a polyuria, it never, except in the early stages, and then not as often as supposed, causes a pollakiuria, or, as Clado, before his untimely death, more properly named it, a sychnuria.

Even though a polyuria does not as a rule cause a sychnuria, the bladder accommodating itself to the greater demands on its capacity, the converse may well happen that sychnuria can cause a polyuria. Our experience leads us to agree fully with Guyon to the effect that an increase in the frequency of emptying the bladder reflexly increases the kidney secretion and conversely that the decrease or total relief of this abnormal frequency decreases in consequence the quantity of urine.

[12] L'Ataxie Locomotrice d'Origine Syphilitique, 1882.

[13] Congress of the Association Française d'Urologie, 1897.

Of the many examples which could be given to support the above statements I mention but one. This was the case of a Parisian woman who was under our care in September, 1901. She suffered from severe diabetes, discovered in 1895, and had been treated since then with indifferent success. When we first saw the patient the excretion of sugar, in spite of strict diet, amounted to 48 grammes per litre, with a daily quantity of urine of over 3000 cubic centimetres, or a total excretion of about 150 grammes of sugar. In addition there was abundant excretion of acetone and diacetic acid and a trace of β-oxybutyric acid. The specific gravity was 1030, with an ammoniacal reaction, while in the sediment were found mucus, pus, and triple-phosphate crystals. The cystitis was a matter of years' standing and was the cause of an unusual increase in the frequency of micturition; by day the patient had to urinate about every half hour and averaged six or eight times at night; and all of this had been ascribed to the diabetes! As for other symptoms it need only be mentioned that the patient had suffered for years from chronic constipation and had lately lost much weight. I began local treatment of the bladder; the urine soon became clear and acid, with simultaneous disappearance of the sychnuria, *although the polyuria still continued*, and the sugar decreased but slowly, as a diet free from carbohydrates could not be introduced at once on account of the acetone. It was only much later that the sugar and the polyuria decreased together (daily quantity 650 cubic centimetres) and the patient gained weight.

As a *résumé* it may be said that the Carlsbad waters are particularly indicated in diseases of the urinary passages for the following reasons. 1. Because they are notably diuretic. Therefore they have an eliminative action on foreign bodies in the urinary passages, like clots, mucus, pus, or small concretions, such as can be passed out *per vias naturales*. The passages are "well flushed out." Of course, micro-organisms (bacillus coli, &c.) are also by this means washed out. 2. They have a modifying action on the urinary mucous membrane; catarrhs of low grade heal rapidly without local treatment. 3. The Carlsbad waters stimulate both renal and intestinal functions energetically and their use is thus especially indicated in those cases where so-called urotoxic substances are to be eliminated—i.e., in cases of prostatic disease, chronic cystitis, &c.—and in those cases of nephritis where the gastric symptoms prevail. 4. The regulation of intestinal activity has a direct depleting effect on the pelvic organs, bladder, prostate, &c. The venous stasis due to intestinal stagnation is mitigated, the deeper organs are relieved. The increase in volume of the hypertrophied prostate due not to secondary degenerative changes but to a congestive hyperæmia—and in every case a part is congestive—disappears as a result of the regulation of the bowels. 5. Post-operation, after nephrotomy, suprapubic lithotomy, litholapaxy: to wash out the smallest particles of sand; after prostatectomy: to alleviate the cystitis, regulate the bowels, and eliminate the toxins. 6. The Carlsbad treatment is contra-indicated in the common condition of frank uro-genital tuberculosis, so frequently taken for a simple cystitis or pyelitis.

Carlsbad.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on April 26th, Mr. H. H. CLUTTON, the President, being in the chair.

Mr. LAWRIE H. McGAVIN exhibited two cases of Ventral Hernia through an operation-scar treated by the Implantation of Large Filigrees of Silver Wire. The first case, that of a woman, aged 38 years, presented a hernia at the site of the scar of an operation that had been done a year before, the gap measuring 5 inches by 3 inches. The whole of the old cicatrix was removed by an elliptical incision 11 inches in length. One portion of the external oblique aponeurosis was sutured to the cut edge of the posterior sheath of the rectus muscle and upon this, as a bed, a silver wire filigree, measuring 8 inches by 4 inches, was laid, the inner loops being disposed beneath the rectus muscle and the outer beneath the oblique muscles. The remains of the rectus muscle were now brought out of the sheath and sutured as far as possible to the oblique muscles over the filigree. This caused a weak spot at the middle line of the abdomen and necessitated the opening of the sheath of the left rectus muscle, which was drawn across the middle line to meet its fellow, where it was sutured. The skin and superficial fascia were closed over all by 35 Michel's clips. No belt had been worn since convalescence. The second case presented a similar condition after an operation for appendicitis. The scar had been treated in like manner and the result had been most satisfactory.—Mr. A. E. J. BARKER congratulated Mr. McGavin on his results. The method was certainly superior to any he himself had used and saved a great deal of time and manipulation. He had used interlacing wire in about 30 cases and in only two instances had it to be removed subsequently. He referred to the respiratory embarrassment which he had seen occur after the replacement of enormous herniæ.—Mr. McGAVIN said in reply that he had not had to remove the filigree in any of the 16 cases he had done.

Mr. McGAVIN also showed a case of Inguino-scrotal Hernia in a male treated by Implantation of Filigrees of Silver Wire.

Mr. DOUGLAS DREW exhibited two cases illustrating the Use of a Filigree of Silver Wire in the Radical Cure of Umbilical Hernia.

Mr. DREW also showed a case of Habitual Dislocation of the Patella (? Congenital) in a girl, aged 13 years. The child first came under observation when six years old with severe genu valgum and dislocation of the patella when the knee was flexed. Macewen's osteotomy of the femur was performed in April, 1900. The present condition was much the same as seven years ago. On flexing the knee the patella slipped completely over to the outer surface of the external condyle, whereas when the knee was extended it lay over the external condyle. It was suggested to treat the case by dividing the capsule on the outer side of the patella so as to allow of the reposition of the bone, and by shortening up the capsule on the inner side and deepening the patellar surface on the femur.—Mr. WALTER G. SPENCER advised the removal of the patella, care being taken not to damage the aponeurosis.—Mr. DREW recalled a case operated on in the way which he now suggested by Mr. Bilton Pollard 16 years ago, with an excellent result.

Dr. F. E. BATTEN showed three cases of Acute Ataxia (Encephalitis Cerebelli). The first case, in a boy, now aged six years, had been exhibited before the society in October, 1904. In April, 1904, he vomited, had general convulsions, and passed into a comatose condition. On regaining consciousness he was wildly ataxic alike as regards his legs, arms, and trunk. From this he very slowly recovered and when exhibited before the society in 1904 was still very ataxic. He walked fairly well but was still unsteady, especially on the left leg. The articulation was still slow and hesitating. The reflexes were normal. Sensation to touch and pain was perfect. The second case was in a boy, aged 11 years, who was quite well up to April 1st. He had severe headache, vomited a whole day, and was unable to feed himself or to stand. On April 5th he tried to get out of bed and walked like a drunken man. On the 9th he had marked ataxia of both legs, some ataxia of the hand, and nystagmus on looking to the left side. There was loss of tone in the muscles of the lower limbs. The knee-jerks were active and the plantar reflexes flexor. The boy had rapidly improved, so that he now only exhibited slight ataxia in the lower extremities. The third case was that of a boy, aged 12 years, who had always been backward. For the last seven years the patient had had attacks of *petit mal*. In September, 1906, he had a series of 130 fits and was unconscious for three days. On recovery he could move his arms and legs but had no control over them and had not been able to walk since. His mental condition was poor and his articulation was slow and jerky. There was unsteadiness of the trunk and head. There was general weakness of the arms and a well-marked intention tremor was present. He could not walk without aid and his gait was wildly ataxic. Dr. Batten referred to the favourable prospect in these cases and recalled Dr. Frederick Taylor's case that made only slight improvement in the first three years but had perfectly recovered when seen 25 years later.

Mr. C. GORDON WATSON showed two cases of Modified Pirogoff's Amputation in men, aged 30 and 40 years respectively. The operation was performed in the first case for very severe talipes equino-varus following infantile hemiplegia. After tenotomy of the tendo Achillis and subcutaneous division of all contracted tissues in the immediate neighbourhood, excision of the astragalus and amputation of the foot in front of the os calcis, removal of the internal malleolus and the cartilage from the lower end of the tibia and a small portion of the anterior extremity of the os calcis, the patient could now walk well and had a very comfortable stump.—The PRESIDENT remarked that the result of this new operation was excellent.

Mr. REGINALD H. MILLER showed a case of Encephalitis chiefly affecting the Mid-Brain. The patient was a boy, aged three years, under the care of Dr. W. S. Colman at the Hospital for Sick Children, Great Ormond-street. In October last the child was suddenly taken ill with a convulsion, in which the left side of the face was drawn up, and this was followed by three weeks' unconsciousness. When seen in November there was some weakness of the right side of the face and the right external rectus with slight lateral nystagmus. There had been inability to walk or talk, extreme emotionalism, some rigidity of the right arm and leg, and a slow tremor (about five per second) of the head and limbs, which showed more in the proximal than in the peripheral parts of the limbs and was absent only during sleep. The fundi were normal; the abdominal reflexes were absent on the right side and feeble on the left; the knee-jerks were brisk and about equal and the plantar responses flexor. The facial and ocular signs quickly cleared up and the tremor became of the "intention" type; the abdominal reflexes became normal, but the rigidity of the right side remained. He had now regained the power to walk, but could not yet speak intelligibly. Recovery had been slow but continuous.

Dr. W. G. STONE and Dr. F. NORMAN showed a case of Tumour of the Tongue in a boy, aged five years. The right side of the tongue had been severely bitten three years ago. Since then it was reported that there had always been a swelling under the tongue of about the size of a hazel-nut, with a smooth surface and of the same colour as the rest of the tongue. There was now an irregular purple swelling on the under surface of the right half of the tongue with hardened edges.—Mr. BARKER suggested that the case was possibly one of the mixed type of lymphatic nævus.

HARVEIAN SOCIETY OF LONDON.

Ulcerative Colitis.—Functional Nervous Disorders in Childhood.

A MEETING of this society was held on April 18th, Dr. SIDNEY P. PHILLIPS, the President, being in the chair.

Mr. FRANCIS JAFFREY read a paper on a case of Ulcerative Colitis, Appendicostomy, Cæcostomy, with complete recovery, under the care of Dr. A. C. Latham and himself. A man, aged 48 years, was admitted into St. George's Hospital in March, 1906, with severe ulcerative colitis of six weeks' duration; the bowels had acted as often as 18 times in the 24 hours and there had been severe hæmorrhages. Various drugs were given by the mouth without effect and rectal injections of boric acid, silver nitrate, and starch and opium failed to control the symptoms. As the patient was in a precarious condition Dr. Latham asked Mr. Jaffrey to operate. Appendicostomy was therefore performed, but owing to the small size of the appendix satisfactory irrigation was impossible. Five weeks after the first operation, therefore, cæcostomy was performed and then the colon was daily irrigated with listerine, one ounce to the pint, and occasionally with adrenalin, one drachm to the pint, or liquor hamamelidis, two drachms to the pint. In less than a fortnight practically all the symptoms had disappeared, there being no blood, pus, or mucus in the stools. The cæcostomy was ultimately closed and the patient was now in normal health and at work. The case showed the beneficial result of prompt resort to cæcostomy when medicinal treatment had failed, for there was no doubt that the patient must have rapidly succumbed if he had not been operated upon.—Dr. ALEXANDER MORISON spoke of the styptic and antiseptic value of turpentine in cases of ulcerative colitis.—Mr. T. CRISP ENGLISH alluded to the advantages of cæcostomy over appendicostomy.—The PRESIDENT said that only a few cases of ulcerative colitis require operation, amongst other indications being hæmorrhage and obstruction from atony. He referred to the value of mercury by the mouth and of adrenalin injections.—Dr. LATHAM urged that in the really acute cases of ulcerative colitis surgical measures should be advised earlier than was the usual practice, for medicinal treatment usually failed to control the disease.

Dr. LEONARD G. GUTHRIE read a paper on Functional Nervous Disorders in Childhood. He suggested that all depended upon individual instability of the nervous system and not upon the normal physiological instability common to all young subjects. Such instability was manifested in (1) derangement of coördination, shown in nystagmus, head nodding, some cases of strabismus, congenital stridor, enuresis, and stammering; (2) defective control by higher over lower centres, instanced in chorea, the tics, and some cases of recurrent pyrexia; (3) explosiveness of the higher centres, accounting for epilepsy and eclampsia; (4) explosiveness with readily induced exhaustion of psychical, sensory and motor realms characterised hysteria; (5) instability and exhaustibility of all parts of the nervous system explained neurasthenia; and (6) derangement of the sympathetic and vaso-motor system was the cause of many functional ailments such as pseudo-angina, palpitation, tachycardia, Graves's disease, atonic dyspepsia, and enterospasm. The sympathetic system was at the mercy of the mind and most functional disorders were the outcome of the neurotic temperament. The neurotic child was the father of the neurasthenic adult. The various types and characteristics of neurotic children were described. It was held that the neurotic temperament itself was in no sense morbid though likely to become so under injudicious management. Educational over-pressure was attributed chiefly to fact-cramming, strain of defective memory, enforced concentration over uncongenial tasks, fear of failure, and disappointment at want of success. Precocious children were no more liable than dullards to die young.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Exhibition of Instruments.—Eclampsia.—Bier's Hyperæmia in Gynæcology.—Report of the Rotunda Hospital.

A MEETING of this section was held on April 12th, Sir A. V. MACAN being in the chair.

Mr. JAMES S. ASHE exhibited a Vulsellum Forceps which he had had made in order to get over the tendency of the bullet forceps to slip out of the cervix and to avoid the discomfort attending the holding of it for any considerable period. The chief features of the vulsellum forceps were that the points interlocked instead of meeting outside, while they were flatter on the under surface than the ordinary bullet forceps so as to offer a greater resistance and not pull through the tissues. The handles were so shaped that no matter how they were held they were fairly comfortable. There was no difference as to the cost of production.

Mr. A. J. HORNE exhibited for Dr. DUKE a new Uterine Dilator. Dr. Duke said that anyone who had performed the operation of dilatation must have noticed the contraction of the cervix uteri on the curette taking place during the proceeding. The cervical wall might require scraping and owing to the contraction spoken of this became difficult, if not impossible. The cannulæ shown were designed to be introduced after dilatation according to the amount of room required, the curetting being carried on through the cannula, which was gradually withdrawn, thus effectually preventing the contraction of the cervix on the curette.

Mr. J. SPENCER SHEILL exhibited a Chart showing diagrammatically the dates and occurrences during the last three years in connexion with an eclamptic patient. He had brought the case before the Academy a year ago and he thought that the further history of the case would be of interest. About the year 1900 the operation of nephrectomy was performed on the patient for tuberculosis of the left kidney. In 1904 she married and became pregnant. The remaining kidney, having the extra strain of pregnancy put upon it, began to fail, and in March, 1905, when about six months pregnant, she consulted Mr. Sheill suffering from eclampsia. Induction of labour was satisfactorily done, but the child was lost. In August of the same year she became pregnant again. The usual treatment was adopted, and as far as the kidney was concerned it was fairly satisfactory.

In December of the same year the kidney again showed signs of failure. In January, 1906, when she was about eight months pregnant, the symptoms became so marked that he determined to induce labour. He delivered her of a living child and about three hours afterwards she had an eclamptic seizure. Although cautioned as to the dangers of a third pregnancy she again became pregnant and in November, 1906, the kidney showed symptoms of rapid failure. After consultation with two other practitioners, it was determined, in December, when she was only three months pregnant, to empty the uterus. It was emptied by him under anæsthesia, and in about three days the amount of urine became normal. In January, 1907, it was thought advisable to prevent any further pregnancy, and after consultation and with the consent of the husband and the patient her Fallopian tubes were resected. The chart raised certain points of interest, such as the postponement of marriage for at least three years after the removal of one kidney, and the question as to the induction of labour in order to save the life of the mother and the child. There was also the point as to the significance of the amount of urea in the urine. If he had been guided by the amount of albumin he would never have done anything with the case, for it never rose beyond 0·15 per cent., whereas the amount of urea excreted fell as low as seven and a half grains per ounce in 14 ounces in 24 hours. There were also the points as to the advisability of inducing abortion and of sterilisation. The kidney was functioning absolutely normally between the pregnancies, and was quite capable of carrying on its work. The urine was examined at very frequent intervals in order to be quite sure on that point.—Mr. E. HASTINGS TWEEDY said that the result had justified Mr. Sheill's treatment, but he had never heard of a woman being deliberately sterilised when no symptoms were present and when there was no suggestion that she would ever become pregnant again.—Dr. H. JELLETT said that he could not agree with Mr. Tweedy as to the particular boldness or rarity of removing the tubes for renal disease. It was on all fours with the very old treatment of osteomalacia. It was not possible to wait until pregnancy occurred in order to resect the tubes.—Dr. T. P. C. KIRKPATRICK instanced a case of a girl aged 20 years who became pregnant last year and had eclampsia at the time. She died with all the symptoms of failure of the kidneys. At the necropsy it was found that she had old and chronic tuberculous disease of one kidney which had completely destroyed its function; the other kidney was amyloid. She recovered from the eclampsia but died some months afterwards from failure of the single kidney.—Mr. HORNE said that considering the age of his patient (28 years) and her apparent fertility, he thought that Mr. Sheill was perfectly justified in his action. If he had allowed her to become pregnant again he would probably have had to repeat the former operation with less favourable results.

Mr. SHEILL read a paper on Bier's Treatment of Disease (by hyperæmia artificially produced) as applied locally in gynæcology, and some actual experiences with it in a variety of gynæcological ailments were related. Mr. Sheill dismissed the "arterial" hyperæmia produced by hot air and the "venous" hyperæmia produced by "constriction" because he had had no experience of the former and the latter he considered inapplicable to gynæcology. The "suction" form, creating mixed arterial and venous hyperæmia, was the kind he used, and he showed a simple form of apparatus which had been successfully employed in a number of cases. He said that in order to be beneficial the "suction" must be intermittent and must not be so strong as to cause pain. Three-minute applications and one minute intervals for half-hour sittings daily or weekly, as the case might be, were recommended. He also spoke of the value of the intermittent action, "massaging" the uterus being valuable in cases of adhesions and relaxed pelvic ligaments. Mr. Sheill had used the treatment in two cases of amenorrhœa occurring without obvious cause; the results were negative in so far as the menses were concerned, although in one case other pelvic symptoms were relieved. A case of endometritis was very favourably influenced. In two cases of old pelvic exudate and adhesions the result was especially gratifying. Mr. Sheill suggested that the suction treatment would be valuable to prevent the upward spread of the infection in cases of gonorrhœa, as well as for the safe and easy removal of tenacious mucus from the cervix of nulliparæ desirous of becoming pregnant.

Mr. HASTINGS TWEEDY read the report of the Rotunda Hospital for the year 1905–06.

On the proposal of Dr. THOMAS NEILL, seconded by Mr. HORNE, discussion on the paper was postponed till the next meeting of the section.

SECTION OF STATE MEDICINE.

The State and Syphilis.

A meeting of this section was held on April 19th, Dr. F. C. MARTLEY, the President, being in the chair.

Mr. G. R. SEYMOUR STRITCH read a paper entitled "The State and Syphilis," discussing the matter from its financial, vital, hygienic, and legislative aspects. He endeavoured to show that the time had now come for an active crusade to be formulated by the Government and the people against syphilis. He adduced figures to prove that the cost to the nation of venereal diseases in the army, navy, and Government departments amounted annually to no less a sum than £3,000,000, and that allowances for superannuations and for sick leave occasioned indirectly through these diseases, though not appearing in the returns as such, were a further cause of heavy expenditure. In estimating the loss to the nation from death and disablement not only syphilis should be considered but also all those diseases which may be traceable to it. The hygiene of syphilis might be dealt with from the basis of a "trihedron" supporting the principle of morality, sociality, and legislation. Circumcision he believed worthy of being adopted universally. Boys should be encouraged to acknowledge any slip to their fathers. Lectures should be given in schools and ambulance classes on the dangers of venereal disease. He believed that the Contagious Diseases Acts fulfilled their purpose; they ought, however, to be applied not piecemeal to secluded areas but generally throughout the empire. He recommended free dispensaries for men in each quarter of a city, the notification of the disease, and the punishment of those to whom its spread was traced, together with the compulsory detention and segregation of prostitutes whilst in an infectious condition.

Colonel EDWARD BUTT, R.A.M.C., said that his experience of the disease had been limited to the army, but he thought that the medical profession, in common with the general public, did not recognise that, notwithstanding all sorts of moral and educational influences, things were much the same as they had been in the past. His experience, gained during his last three years in India, had led him to the conviction that the disease could be stamped out. During that period, in a garrison of 1000 men, he had not one case of syphilis, although there were many prostitutes living on the confines of the garrison, and none of these contracted syphilis. The accomplishment of this was made easy for him by the magistrates, officers commanding, and his brother medical officers working with the one desire of stamping out the disease. They induced the soldiers to believe that they could benefit them by submitting to treatment. There was no stigma attached to women who suffered from venereal diseases going into the cantonment general hospitals, and the native women attendants were taught to explain to the women the benefits of treatment. The result was, he thought, strong presumptive evidence in support of his contention that so long as local manifestations of the disease had been removed and the treatment was continued the disease could not be communicated.

Dr. HENRY FITZGIBBON said that the difficulty which had always existed in dealing with patients in the Lock Hospital had been the absence of controlling power to get them to remain under treatment. Power was required to keep prostitutes in hospital as long as there was active syphilis present, and to keep them under observation and treatment as extern patients afterwards. There was also a difficulty in connexion with young men who had not the means to pay for treatment and who had no encouragement to go to general hospitals.

Major BROWN, R.A.M.C., said that the majority of those who indulged in sexual vice were not open to moral persuasion. Women who practised as prostitutes could not be prevailed upon to submit to treatment for a sufficient period and the only practicable way was to compel them to remain in hospital or to report themselves to a medical practitioner until they could be certified as free from the disease. The efforts that had been made to stamp out the disease in the army did not seem to have had much effect. In Dublin, in 1906 the constantly *sick from syphilis were* 2·93 *per* 1000, while in 1866 the proportion was 1·72 per 1000.

Dr. T. P. C. KIRKPATRICK said that the question of State interference was as old as history. So far back as the year 1162 Parliament interfered for the regulation of brothels. It was a *mistake to suppose that there was no regulation for* State interference with venereal disease in Dublin. Under the Act of Parliament 5 Vict., c. 24, the police dealt very severely with prostitutes and soliciting, and in the Act 48 & 49 Vict. there were very stringent regulations for the suppression of brothels. He had received from the Commissioner of Police a table showing the number of women proceeded against during the last five years, 601 being dealt with in 1906. During the same period 20 brothels had been suppressed in each year. Syphilis was not always, as was urged by some persons, a merited disease. The morbidity and mortality of the disease justified them in urging the State to interfere in the matter. The sentiment of the country was against the official registration of prostitutes, and he would rather follow the suggestion that the laws at present in force should be used against solicitation, and a man who could be proved to have infected a woman with syphilis should be liable to similar punishment.

Colonel CHARLES H. BURTCHAELL, R.A.M.C., said that he had been in several American cities where prostitution was rampant, although the police arrangements absolutely prevented soliciting. If the prostitutes did not find the men, the men would find the prostitutes. Syphilis was due to a voluntary act. If legislation was enacted it should be equally severe on the man and the woman, and he thought that there should be some restriction on the *marriage of* syphilitic persons.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 19th, Dr. J. Lindsay Steven, the *President*, being in the chair.—Mr. H. Rutherfurd read :—Notes of a case of Cerebellar *Abscess* following Otitis Media. The symptoms were headache and dizziness and mastoid abscess was diagnosed. Under treatment the symptoms disappeared and the patient was sent to a convalescent home to improve his general condition before operation. On re-admission he had frontal headache and was apathetic and livid. The pulse was from 52 to 62. After the radical *mastoid* operation the pulse ran up to 116 but fell again. There was no recurrence of duskiness until the sixth day when it came on suddenly with coma. Respiration failed and he died. Miss M. Hannay performed a necropsy and found a cerebellar abscess. There was no suppuration at the base of the brain. Granulation tissue was found around the eighth nerve. 2. A case of Fat Embolism of the Brain after Simple Fracture of the Leg. 3. A case *operated* on for Otitis Media with Sinus Thrombosis. Dr. H. Wright Thomson read notes on the Condition of Retro-bulbar Neuritis which developed. Sinus thrombosis developed *three months* after the mastoid operation and the internal jugular vein was ligatured. Vision rapidly failed and the left eye became quite blind. The external appearance was normal. The vision of the right eye was $\frac{6}{6}$. There was central colour scotoma. The optic discs were very white with irregular margins. The laminæ cribrosæ were invisible. A month later vision was $\frac{6}{36}$ and colours were recognised. The papillitis in this case was considered to be secondary to the retro-ocular neuritis. The patient had influenza before operation and the condition was probably of *toxic* origin.—Dr. J. Stoddart Barr showed : 1. Three cases operated upon for Empyema of the Mastoid Cells in which the resulting cavities were filled with the iodoform wax of Mosetig-Moorhof. In Case 1 six days, in Case 2 *nine days*, and in Case 3 12 days passed after the mastoid operation before the cavities were filled with the iodoform wax. Healing was complete in 16, 18, and 21 *days* respectively after the vertical cells had been curetted. In all the cases the otorrhœa had ceased, the post-auricular scar was *slight* with no depression, and the hearing greatly improved. A contrast case was also shown in which the older method of packing with *gauze strips* had been adopted and in which healing was not complete until 12 weeks after the operation, leaving a marked depression behind the ear. 2. A patient, aged 49 years, from whose Nose a Foreign Body had been removed which had been there for fully 40 years and had excited severe and constant headache. By posterior rhinoscopy pus in large quantity was seen filling the left choana. The left middle turbinal was removed as sphenoidal or posterior ethmoidal disease was diagnosed. It *was only after this had been done* that the foreign body, a piece of indiarubber one inch square and covered with pus, was seen lying upon the anterior wall of the sphenoidal sinus. Its removal, which was easy, was followed by complete cessation of the headaches.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 5th, Dr. W. C. Chaffey, the President, being in the chair.—Dr. Walter Broadbent showed a man with Aneurysm of the Third Part of the Arch of the Aorta, having a brassy cough, paralysis of the left vocal cord, tracheal tugging, dulness and pulsation in the left second space, with a harsh systolic murmur and a loud second sound over this area and the aortic region, also diminished air entry in the upper lobe of the left lung. He also showed a case of Basic Phthisis in a young man with a large cavity in the left lower lobe and only very slight signs in the apices.—Mr. H. H. Taylor showed a woman with a Swelling in the Region of the Right Lacrymal Gland of recent origin and a subsequent swelling of the forehead. There was also a node on the right tibia and the diagnosis lay between sarcoma and gumma.—Mr. T. H. Ionides showed a Stone three inches long and three-quarters of an inch in diameter which he had removed from the ureter of a man in whom he had twice crushed stones in the bladder.—Mr. R. F. Jowers showed an Extra-uterine Fœtation of the Tubo-ovarian type which he had removed by operation.—Dr. C. F. Bailey showed an x ray photograph of a Tuberculous Wrist.—Mr. H. H. E. Scatliff read notes of a case of Lymphatic Leukæmia which he had *first seen in January for a hæmatoma* of the inguinal glands which he had opened, letting out pus and blood. Subcutaneous hæmorrhages then developed with a high septic temperature and the gums became *spongy* and bled easily ; there was also diarrhœa with blood in the *motions*. The blood was examined and found to contain 64,000 leucocytes, *of* which 45,000 were lymphocytes. The patient died in March.—Mr. Taylor read some notes on the Royal Commission *on* Tuberculosis, remarking that it was appointed after *Koch's statement that* bovine and human tuberculosis were distinct diseases, not transmissible from cow to man or *vice versâ*. The Commission had found that human tuberculosis was infective to cattle, if given in sufficient dose, but it was less virulent than bovine. Two kinds of human bacilli had been differentiated, one more virulent, like bovine, and difficult to grow on media, the other less virulent but easier to grow. In 60 children examined they found the bacilli analogous to bovine 14 times. Of 23 cases of abdominal glands examined 19 contained bovine bacilli. In 20 tuberculous cattle the milk was virulent to guinea-pigs 11 times. It therefore seemed clear that bovine tubercle was transmissible to man as well as human to cattle.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN.—A meeting of this society was held on April 24th, Dr. Leslie Roberts, the President, being in the chair.—Mr. G. W. Dawson *showed* : 1. A woman, aged 79 years, with Paget's Disease of the Left Breast which he had treated with x rays. The case had been previously exhibited before *the society* and the members were agreed that considerable improvement had taken place. 2. A boy, aged 14 years, with generalised Keratosis Pilaris *associated* with a *slight* degree of Ichthyosis. The palms and the soles were *free.—Dr. E. G. Graham* Little showed : 1. A case of Tuberculosis of the Ear in a girl aged 13 *years*. There was a necrotic condition of the margin of the left *pinna which had existed*, off and on, for seven years. There was no *history* of any local inoculation, but the child came of a markedly *tuberculous* stock. 2. A man, aged 40 years, with Ringworm of the Nails. The *case was* remarkable in that every finger-nail of both hands was attacked *by the disease*. The mycelium had been identified and the condition had *lasted for fully* 13 years.—Dr. Alfred Eddowes exhibited : 1. A *case of* Syphilitic *Alopecia* in a young woman, of five weeks' duration, associated with *much* tenderness of the scalp which, together with some local œdema, was the *most* conspicuous feature of the case. 2. A man, aged 57 years, with a Secondary Syphilitic Eruption of a somewhat unusual type. Upon the abdomen the lesions presented a shiny, lichenoid appearance, while upon the *forearms* the rash assumed a scaly, psoriasiform aspect. The condition had lasted for *four* months and before being seen by the exhibitor the patient had *been* rubbing in an *ointment* his description of which suggested that it might have contained chrysarobin.

Reviews and Notices of Books.

The Diseases of Infancy and Childhood. By HENRY KOPLIK, M.D. Second edition, revised and enlarged. London: Henry Kimpton. 1906. Pp. 885, with 184 engravings and 33 coloured plates. Price 25*s.* net.

THE second edition of Dr. Henry Koplik's work on the diseases of infancy and childhood does not materially differ from the one that preceded it, a result that is hardly surprising, seeing that the first edition was itself notably up-to-date and very complete in detail. The section on infant-feeding has, however, been recast to the exclusion of certain theoretical considerations which had little bearing on the practical management of infants and with the inclusion of certain new details which can be readily applied and carried out by the practitioner. More attention has been given to the physiology and pathology of the newly born infant than was devoted to these subjects in the first edition or indeed than is usual in text-books of this kind. The section which deals with the specific infectious diseases, and which we particularly commended in a previous review, has received extensive additions, and is in every way worthy of Dr. Koplik's reputation in this department of medicine. In view of the recent epidemic of cerebro-spinal meningitis the chapter which deals with the subject will probably be referred to with some degree of interest, since it represents the latest views of an expert on this question. The author states that in the epidemic form of the disease the diplococcus meningitidis intracellularis of Leichtenstein, Weichselbaum, and Jäger is in the vast majority of the cases the specific cause of the disease, although there is another form of cerebro-spinal type which is caused by the diplococcus pneumoniæ. As to the manner in which the infection is conveyed, a question which is still one of speculation, the author seems to incline to the view that the diplococcus may be disseminated by means of the secretions of the eye and the nose, although he particularly warns his readers against confounding the micrococcus catarrhalis, which is often found in the normal secretions of the nose, with the specific form of the diplococcus intracellularis. But however probable it is that the infection may be carried in this way Dr. Koplik adds that the facts as far as they are known do not definitely establish how the infectious material gains access to the circulation, or whether, indeed, the disease is even conveyed from one person to another. His account of the manifestations of the clinical symptoms, the early diagnosis of the disease, and the bacteriology is well worth reading and could hardly be improved upon even in the light of the great amount of work which has since been done in this disease in consequence of the recent epidemic in this country.

We notice several new illustrations and additional charts in the present edition, and in every way we regard Dr. Koplik's revised volume as a most trustworthy and useful text-book for students and practitioners.

Die Neurologie des Auges (The Neurology of the Eye): A Handbook for Neurologists and Ophthalmologists. By Dr. H. WILBRAND, Ophthalmic Surgeon; and Dr. A. SAENGER, Physician for Nervous Diseases to the St. George's Hospital, Hamburg. Vol. III., Part 2: General Diagnosis and Symptomatology of Visual Defects. Wiesbaden: J. F. Bergmann. 1906. Pp. 623. Price £1 2*s.* 6*d.*

Dr. Wilbrand and Dr. Saenger continue to issue from time to time fresh instalments of their monumental work upon the neurology of the eye. The treatise as originally announced was to be complete in three volumes. Four volumes have already appeared, for Volume III., split into two halves of 474 and 623 pages respectively, consists of two volumes in all but name. Two further volumes are now expected to complete the work but we have no information yet as to how many "halves" they will contain. Criticism of such a gigantic undertaking, if not superfluous, savours of impertinence, and we are disposed to sum up our thoughts in characteristic German fashion by the one word "Kolossal!" To do so, however, would be to shirk responsibility and would be manifestly unfair to the authors. In sober truth our admiration for the extraordinary industry and pertinacity of Dr. Wilbrand and Dr. Saenger is equalled, if not surpassed, by our appreciation of the accuracy and immense value of their treatise. Neurologists and ophthalmologists alike must in bounden duty, if not in spontaneous enthusiasm, acknowledge their profound indebtedness to the authors. Here we find gathered together and conscientiously sifted well-nigh all that is worthy of survival in the literature of the subject. It is true that the English reader will discover important lacunæ; he will fill them better than foreigners, for of course they represent the work of his fellow-countrymen, with which he is quite familiar. So habitual is this feature in German books that it is futile to comment upon it and we are duly grateful to find that the work of Gowers, Head and Campbell and some other English observers receives recognition.

It will have been realised that the treatise is encyclopædic, and, as such, is essentially a work of reference. It is, however, astonishingly readable when taken in small doses, and this is largely due to the fact that the authors' own knowledge of the subject is not only encyclopædic but is illuminated by vast practical experience. They make the dry bones live by their own vivifying influence. We may not always agree with them, though we generally do, but in any case their presentation of the arguments cannot be dismissed with contempt.

The general diagnosis and symptomatology of various forms of amblyopia and amaurosis with which vol. iii., part 2, opens are treated in a particularly masterly and helpful manner. The various combinations of normal and pathological conditions of the central vision, the field of vision, adaptation, the pupil reactions, and the fundus oculi as seen by the ophthalmoscope, in their relation to the underlying disease could scarcely have been better presented. The relationship of the deep and superficial reflexes to visual defects is next discussed, followed by that of disturbances of sensation and of mobility to various forms of amblyopia. The disturbances of speech in their association with amblyopia bring this chapter to a conclusion.

The second and final chapter deals at great length (pp. 643–1044) with every conceivable cause of sudden amaurosis. After reviewing the influence of sex, the site of the lesion, sudden unilateral and simultaneous bilateral amaurosis, the nature of the amaurosis, and its influence upon the mind and character of the individual, the authors discuss the various causes—tumour, cerebral hæmorrhage, embolism and thrombosis, injury, lightning, infection, uræmia, meningitis, loss of blood, intoxication, functional nervous disease, migraine, hysteria, epilepsy, chorea, and blepharospasm. We think that they would have done wisely if they had not devoted so much space to many of these causes—e.g., injury—which cannot be so exhaustively or satisfactorily discussed in a work of this nature as in special monographs.

The book is excellently printed and well illustrated. The fact that the micro-photographs are so much better than is usual in German publications probably accounts for the enthusiasm which the authors evidence towards Dr. Reuter who prepared them. They are adequate but by no means superlatively good. There is a good index, but this might have been made much more exhaustive with advantage, for the treatise will certainly be used chiefly as a work of reference, and as such we commend it very heartily to all neurologists and ophthalmologists.

LIBRARY TABLE.

Sanitary, Maritime, and Quarantine Council of Egypt: Scientific Reports of Members of the Medical Staff. Edited by MARC ARMAND RUFFER, President of the Council. Alexandria: Société de Publication Egyptienne. 1905. Pp. 206.—The papers in this interesting publication are based on the work done in the laboratories of the Sanitary, Maritime, and Quarantine Council of Egypt. These laboratories were established primarily for diagnosis but members of the staff were encouraged to spend their spare time in bacteriological and pathological investigation and the results of this encouragement have borne good fruit. The opening paper is one on the Diagnosis of Vibrios, by Dr. Milton Crendiropoulo of Alexandria, in which he considers the characteristics of cholera and dysenteric *organisms*. The author has endeavoured to base a method for the diagnosis of these organisms on their different biological reactions, such as the agglutination, saturation, Pfeiffer's and fixing tests. He describes also the hæmolytic properties of the cholera vibrios. Dr. Felix Gotschlich writes on the Cholera and Cholera-resembling Vibrios met with in the Pilgrims returning from Mecca. Dr. O. Zirolia contributes a short paper on Six Vibrios Isolated from the Water of Ships calling at Port Said. This is followed by an interesting paper by Dr. Armand Ruffer and Dr. Crendiropoulo on the Presence and Formation of Agglutinins in the Blood. In this article are considered the agglutinating properties *of cultures* freed from bacilli, of the formed constituents of the blood, of *non-immunised* and immunised animals, and also of their polynuclear *leucocytes*. Dr. Crendiropoulo and Miss B. Sheldon Amos follow with a paper on the Agglutination of Vibrios, in which they show that chloride of calcium greatly favours this phenomenon, and this result they in a further paper elaborate as regards the true cholera vibrios. Dr. Ruffer writes on hæmolytic and on hæmosozic serum, and on the toxic properties of bile and on antihæmolytic serum. By the same author, in conjunction with Dr. Crendiropoulo, is a note on hæmosozic sera and those substances favouring and inhibiting the action of the hæmolysins of bile and serum; on the lysogenic and hæmosozic properties of urine; on the hæmosozic power of chloride of *sodium* and its mode of action; and on a hitherto undescribed change in the urine of patients suffering from nephritis. Miss Sheldon Amos writes next on the effect of ligature of one ureter. Next follows the description of a newly devised technique of bacteriology by Dr. Ruffer and Dr. Crendiropoulo, by which the diffusible products of the life of micro-organisms can be obtained without subjecting them or the culture media to the action of heat, filtration, or chemical reagents; then a note on the dialysis of toxins through collodion walls, whilst the final paper deals with the results obtained by disinfection and isolation against cholera. These valuable reports contain much interesting work which reflects great credit on the authors.

Reports on the Commission appointed by the Admiralty, the War Office, and the Civil Government of Malta for the Investigation of Mediterranean Fever under the Supervision of an Advisory Committee of the Royal Society. Part V. London: Harrison and Sons. Pp. 85. Price 2*s.* 6*d.*—The first report of this volume is one by Staff Surgeon E. A. Shaw, R.N., on Experiments with Monkeys on Various Possible Paths of Infection in Mediterranean Fever. The results of his researches in this respect show: (1) the possibility of infection through the eyes and nose by means of highly infected dust; (2) the possibility of infection by unlimited contact; (3) the possibility of infection by food contaminated with pure cultures of the micrococcus Melitensis and with dust soiled with urine containing this organism; and lastly, the possibility of infection by the urine of patients through skin scratches, wounds, and abrasions. *Staff Surgeon Shaw next contributes* a paper on Immunity, Serum, Toxin, and Vaccine *Experiments on* Monkeys with regard to this fever. He finds that animals which have previously had an attack of Mediterranean fever react much less markedly than others which have not to the same doses of the living specific organism, hence a previous attack confers some protection. With regard to the future successful development of a therapeutic serum the experiments did not give any hopeful indication. It was also found that the toxins of the organisms did not produce the same clinical phenomena as the living micrococcus Melitensis, no fever being developed and the production of agglutinins being less; whilst the author considers that his experiments afford an extremely hopeful outlook with respect to the future of protective inoculation in man against the fever. The same writer also makes some interesting observations on goats, cats, and rats, and ambulatory cases in connexion with Mediterranean fever. No seasonal prevalence of the fever amongst goats similar to that existing amongst man was found to exist in this respect but the number of animals examined here was small. Dr. J. W. H. Eyre writes on the Micrococcus Melitensis and Anti-serum. No protective properties were found nor were any therapeutic results obtained. Major W. H. Horrocks, R.A.M.C., contributes an article on the Mediterranean Fever *in Gibraltar*, in which he shows that the rapid disappearance of the disease, which commenced in 1905, was intimately connected with the *exodus* of infected goats from the Rock, the effect of which was far greater than any caused by the part played by improved sanitary conditions, such as the disconnexion of waste pipes and house drains from sewers, and so on. The report concludes with a very complete bibliography of the disease.

The Control of a Scourge or How Cancer is Curable. By CHARLES P. CHILDE, B.A., F.R.C.S. Eng., Surgeon to the Royal Portsmouth Hospital. London: Methuen and Co. 1906. Pp. 299. Price 7*s.* 6*d.* net.—This book is not intended for the members of our profession so much as for the public and for those non-medical workers who are able to influence the public by the dissemination of highly important knowledge. Though there is *nothing new* in the book, Mr. Childe puts forward the most recent ideas in regard to cancer and its treatment very clearly; his plea to the public to go early to the surgeon and not to allow any delay should carry conviction. As Mr. Childe says: "To any who will take the trouble to study this question, to any who will look into the results of former years and compare them with the results to-day, the fact that a revolution has been in progress during the last quarter of a century in the treatment of cancer is clear." The book is an attempt to substitute sound knowledge and hope for ignorance and despair. A quarter of a century ago cancer was considered alike by the medical *profession* and the public a hopeless complaint; even the signs by which *students* were taught to recognise it were those of the disease in its advanced and therefore incurable stage. The operations were performed with the view of prolonging life and temporarily alleviating suffering. This, however, is not the general attitude of the profession towards cancer to-day. The objective of the surgeon is to cure. An organised system of education in the early signs of cancer is of the greatest importance. Leaving out of the question the education of the medical student, the author thinks that nurses, midwives, the wives of the clergy, district visitors, and others could be trained in the knowledge of the early *signs* of cancer. The author impresses on the public: (1) that cancer is, in its beginning, a local disease and is confined at first to the part which it first attacks; and (2) that from its local site of origin it generally very soon disseminates itself into the system of its victim. In the chapter entitled, "A Glimpse of the Goal," he assures his readers that "cancer itself is not incurable, but that it becomes incurable from the simple fact that its unfortunate victims harbour and nurse their cancers till it is too late. It is not the disease which is incurable, it is the delay that makes it so." Mr. Childe, of course, recognises that science may some day trace cancer to its source and that possibly a cure other than by operation may then be found. But, as he says, it is useless to indulge in speculation, and the cardinal fact is that at present early operation is the only remedy, and it is folly to attempt any other treatment while the disease is still capable of removal.

Alcohol: the Sanction for its Use. Translated from the German of Dr. J. STARKE. London: G. P. Putnam's Sons. Pp. 317. Price 6*s.*—The volume before us is a contribution to the great controversy on the use of alcoholic beverages that will at first sight perhaps be joyfully hailed by that party which the author denominates as "alcoholists"—i.e., those who are accustomed to their use in moderate quantities; but if they inquire further they will find that Dr. Starke's argumentative zeal is scarcely tempered with that logical discretion which is desirable in approaching so debateable a matter. The book is informed with a casuistry of which the following argument forms an excellent example. He premises that in 25 per cent. of cases of arterio-sclerosis there is a history of chronic alcoholism, and then proceeds to argue that because 75 per cent. of cases occur without such a history we are not justified in concluding that the alcohol was the causative factor in any one of the 25, but that "so and so many would have occurred without it and must have been due to some other cause." In another chapter the author insists strongly that the use of caffeine is responsible for much of the increased nervous stress of modern life, but he allows the cup of coffee provided that its injurious effect in dilating the visceral vessels and contracting those of the skin be counteracted by a moderate dose of alcohol. If it be requisite to set such a thief to catch a thief, the regular ingestion of a post-prandial tabella of nitro-glycerine by all tea or coffee drinkers should *a fortiori* receive the author's support. Alcohol is strongly supported as the only article consumed by us that decreases our nervous excitability. The existence of confirmed drunkenness is put down not to the deleterious effects of alcohol but to the special degenerative tendency of the individual and his environment. We are told even that "the moderate drinker has no poisoning of the brain, provided it is only occasionally he gets 'elevated.'" The effects on the heart and liver of those who habitually live too well are laid more at the door of the extra fluid and nourishment consumed in their alcoholic beverages than of the alcohol itself; in fact, they are advised to reduce their diet to compensate for the extra nourishment in their wine and beer. Dr. Starke appeals unconvincingly to everyday experience and common sense in defence of the general use of alcohol, and makes fusel oil and caffeine the scape-goats for its alleged iniquities. Although he ostensibly collects the scientific evidence in the matter the results of Kraepelin's experiments are ignored. In conclusion, we record our conviction that no one is likely to be shaken in his opinion by the perusal of this book, except perhaps a few "alcoholists" to whose sense of logic it has proved too severe a shock! The translation appears to have been carefully done.

Lectures on Medicine to Nurses. By HERBERT E. CUFF, M.D. Lond. Fifth edition. London: J. and A. Churchill. Pp. 269. Price 3*s.* 6*d.* net. *Nursing, General, Medical, Surgical.* By WILFRED J. HADLEY, M.D. Durh., F.R.C.P. Lond., F.R.C.S. Eng. Second edition. London: J. and A. Churchill. Pp. 370. Price 3*s.* 6*d.* net. *Sick Nursing.* By H. DRINKWATER, M.D. Edin. "The Temple Primers" Series. London: Dent and Co. Pp. 138. Price 1*s.* net.—Of the making of text-books there is no end and the reappearance of two manuals that we have before reviewed reminds us of the increasing choice of books to which nurses can turn for guidance. Dr. Cuff's contention in his preface that the nurse must rely on medical text-books for a brief account of individual diseases hardly now holds good but we will say at once that she could not turn to a more admirable work of its kind than his own. It embodies instruction that is now probably imparted to nurses training at every large hospital and many small ones by their lecturers on medicine, but it would hardly be possible to find a more clearly and succinctly expressed account of the leading symptoms and *rationale* of treatment of the chief medical diseases affecting the various systems. Dr. Cuff's sole object is to assist nurses in the intelligent appreciation of their duties and he repeatedly warns them against the danger of letting a fuller knowledge tempt them to overstep their office. We previously suggested that this little book might prove useful to the student entering on the strange field of clinical medicine and a fresh reading of it warrants us in repeating this suggestion. The chapter on Hysteria will prove especially useful to those unused to dealing with its manifestations. Dr. Hadley's volume has reached a second edition. It deals more shortly with separate diseases but embraces the wider field of surgical and puerperal nursing; the latter subject we consider would be better treated in a separate manual. The book affords a useful and adequate manual of instruction in modern nursing and, although it presents no strikingly new feature, is carefully written and arranged and therefore likely to find a place amongst the standard text-books on the subject. Dr. Drinkwater's book is, we learn, intended for the use of students attending lectures in connexion with the St. John Ambulance Association and evening continuation classes. It certainly contains information which would be profitable to such students but it is devoid of that system which should be adopted in even the most elementary manual—e.g., the chapter on Disinfection includes bronchitis, dropsy, appendicitis, and gout, each treated in a few lines.

The Kennel Encyclopædia. Edited by J. SIDNEY TURNER, M.R.C.S. Eng., Chairman of the Committee of the Kennel Club. Part I., Vol. I. Sheffield: The Encyclopædic Press. 1907. Pp. 112. Price 5*s.*—This is the first part of a serial publication which is to give us encyclopædic information about dogs, and takes us from "abdomen" to "badger"—i.e., it practically comprises the letter A. The contents are of considerable medical interest inasmuch as such subjects as alopecia, anæmia, asthma, amputations, anæsthetics, and antiseptics are dealt with, as well as the ancestry of the dog and its possible use in ambulance work. The articles on Veterinary Medicine by Professor F. Hobday, F.R.C.V.S., and Mr. F. W. Cousens, M.R.C.V.S., are short and exactly what they should be when addressed by a professional man to a lay audience—that is to say, they help the layman to grasp the situation which has to be dealt with, but they do not encourage him to damage the chances of his dog's recovery by inexpert medication. Major E. Hautonville Richardson writes on the Value of Dogs as Ambulance Assistants, and expresses a more favourable opinion upon their possible uses than we should be prepared to do. Mr. R. I. Pocock, F.L.S., superintendent of the gardens of the Zoological Society, contributes a very interesting article upon the canidæ generally, and shows that the rough classification into dogs, wolves, jackals, and foxes, which we find in most popular writings upon the ancestry of the dog, cannot be brought into accord with scientific classification. The "Kennel Encyclopædia" promises to be a most useful work of reference. It is proposed to complete the work in four volumes of four parts each, but judging from the fact that one whole part has been required for the letter A we should not be surprised to learn that a supplementary volume was required.

JOURNALS AND MAGAZINES.

The Bio-Chemical Journal. Edited by BENJAMIN MOORE, M.A., D.Sc., and EDWARD WHITLEY, M.A. Vol. II., No. 4, April 2nd, 1907. Published by the Bio-Chemical Department, Johnston Laboratories, University of Liverpool. Annual subscription for volume of about 480 pages, 15*s*.—The articles contained in this number are: 1. On the Catalytic Decomposition of Hydrogen Peroxide by the Catalase of Blood, by C. A. Lovatt Evans. Mr. Evans shows that there is an optimum concentration of hydrogen peroxide for each concentration of enzyme. The optima do not vary directly as the enzyme concentrations but more nearly as their square roots. 2. On the Influence of Kreatinin in Modifying certain Reactions of Sugar in Urine, by Hugh Maclean. The author shows that kreatinin is the substance which in normal urine interferes with Fehling's solution by holding the reduced suboxide dissolved and that the inhibitory effect is not due indirectly in the application of that test to the generation of ammonia. The proportion of kreatinin present in urine affects the colour of the precipitate. A yellow precipitate takes place where the cuprous hydrate is finely divided, a red precipitate where it is granular. Kreatinin when boiled with caustic alkali of half the strength in which it is present in Fehling's solution quickly diminishes in amount, part becoming converted into kreatin and part being destroyed. Kreatin resists the action of caustic alkali much longer than kreatinin. 3. On Zymoids, by A. R. Bearn and W. Cramer. The authors show that strong solutions of enzyme heated to about 60° C. for half an hour have a strongly inhibitory effect on the unheated enzyme. The inhibition is destroyed at 100° C. and is not due to an antiferment; it is brought about by a reaction between the substrate and substances present in the enzyme that has been rendered inactive. These substances dialyse only very slowly through parchment. These facts point to the existence of zymoids which are probably pre-formed in the enzyme preparations. 4. The Coagulation of the Blood and the Effects of certain Drugs and Toxins upon it, by C. J. Coleman. 5. The Excretion of Kreatinin in a case of Pseudo-hypertrophic Muscular Dystrophy, by E. I. Spriggs. The quantity of kreatinin discharged is diminished.

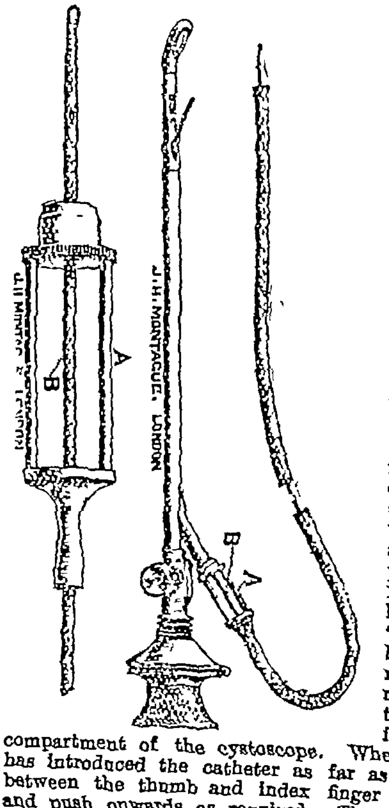
Man.—The April number contains photographic portraits of 22 representative members of 16 Bantu South African tribes. These natives were brought together at the Victoria Falls by the Government of Rhodesia in 1905 in order that they might be seen by the members of the British Association for the Advancement of Science, the annual meeting of which was then being held in South Africa.

Caledonian Medical Journal.—The April number of this journal opens with a long article on the Laminaria Tent, contributed by Sir William Sinclair, professor of obstetrics and gynæcology in the Victoria University of Manchester. He expresses his "firm conviction that just as the curette was discredited, owing to universal professional ignorance of the conditions essential to safety and fell into disuse for a time, so the laminaria, properly prepared for gynæcological and surgical purposes ...... will be ultimately recognised throughout the civilised world as the unique material." He gives the following directions for making aseptic laminaria tents. "Shape the tent while the tangle is fresh out of the sea, perforating as required. Desiccate completely. Place in solution of perchloride of mercury (a solution of 1 in 2000 is quite strong enough) until the tangle regains its original size by saturation with the solution. Again completely dry the tent. Finish by polishing and introduction of strong linen thread." The tent may remain *in situ* 24 or even 48 hours with advantage. No force should be employed in introducing it and before use it should be softened in hot water or in hot antiseptic solution. In the editorial columns it is announced that the annual meeting of the Caledonian Medical Society will be held in Bradford on July 26th and 27th.

New Inventions.

ASEPTIC URETERAL CATHETERISATION SHEATH.

THIS comprises two detachable portions—viz., metal and rubber. The metal one consists of a perforated screw cap and a conical-shaped portion (with broad base and funnelled apex); these are fixed to one another by two thin side rods marked A in the diagram. The screw-cap is a replica of the one on the upper end of the compartment for transmitting the ureteral catheter of the *Nitze catheterisation* cystoscope. A piece of rubber tubing, 22 inches long and with a bore of *one-eighth* of an inch, completes the apparatus. The rubber tubing is made to slip over the bulbous bell-mouthed apex of the "cone" and the whole is *screwed on* to the cystoscope. The ureteral catheter having been introduced into the rubber tubing the catheter is pushed onwards. Owing to the funnel-shaped apex of the metal portion the catheter B readily enters the lumen of the "cone," reappears between the two metal *connecting* rods, and negotiates the orifice leading into the ureteral compartment of the cystoscope. When the *vis a tergo* has introduced the catheter as far as possible grasp it between the thumb and index finger of the right hand and push onwards as required. The advantages of this sheath are obvious. It is simplicity itself. The present real dangers from sepsis owing to the catheter touching the operator's face, hair, and being breathed upon are avoided. It is easily sterilised, for both rubber and metal portions will boil. Excepting for the end remote from the tip there is no need to handle the ureteric catheter until it is well inside the cystoscope. The rubber tubing can lie anywhere, over the cystoscopist's shoulder, in between the patient's legs, &c. *Without* this addition there is a great liability for the catheter to double up at the point of handling when it is being pushed onwards; the opposing thumb and index finger slide up and down the side rods and give the necessary support. It is necessary to use a lubricant for the rubber tubing in order to make the catheter travel more easily; a suitable one is *paroleine*, made by Messrs. Burroughs, Wellcome, and Co., and as this has now replaced glycerine as a urethral lubricant it is always handy; it may be introduced by a sterilised



pipette. It is always as well to have a few spare "washers" in the cystoscope box, for when the sheath is being sterilised this washer in the screw cap is apt to boil out and is lost. The cable attachment to the cystoscope should point upwards so as not to be in the way of the "sheath" during manipulation. Gum elastic tubing has been tried in place of the rubber but the latter is more suitable. A spring arrangement for grasping the catheter while it is being pushed onwards in order that the fingers do not come in contact with it at all was too complicated. In lieu of this the hands must, of course, be efficiently sterilised before touching the catheter. The illustration also shows Mr. John Pardoe's most excellent eye-piece fitted on to the cystoscope.

The "sheath" may be obtained from Mr. J. H. Montague, 69, New Bond-street, W.

R. J. Willan, M.B., B.S. Durh.,
Senior House Surgeon, St. Peter's Hospital for Stone, London.

A NEW INSTRUMENT FOR TREATING GLEET.

For some six years I have successfully used a method of treating chronic urethritis, chiefly where the follicles are engaged, and I can recommend it to others where ordinary methods fail. This method embraces (1) the emptying of the follicles by aspiration and the passage of large bulbs; and (2) when they are empty and kept patent the injection of certain solutions into them by means of a large injector. Follicular urethritis is common, especially in the prostate, and its treatment is difficult and uncertain. Tersely, the enigma presented is to get the secretion out of, and the injection into, the follicles and utricle. Up to the present time massage, the passage of large sounds, Kollman's dilator, and sometimes the obliteration of the follicles of the penile urethra by caustic or electric action were the aids possessed by surgeons. The first three are often inefficient, while the last two are of only occasional utility and are always difficult. At first I used Erichsen's syringe, to which I attached a small aspirator. It was too small and the metal between the holes pressed transversely on the ducts. The instruments represented in the accompanying figures are much more effectual; Fig. 1 is for the deep urethra and Fig. 2 is for the anterior urethra; Fig. 3 is a connexion for an aspirator. The perforations are oblong. A and A are indiarubber discs which travel on the instruments and block the meatus. Barred instruments may be used. Having well smeared them with liquid paraffin the particular one selected is introduced, an aspirator or exhausting syringe is applied, and an intra-urethral negative pressure is slowly and gently created. The urethra is then flushed and swept clear of its secretion by a large bulb shaped like a turkey's egg. The injection is then used through these instruments or other large injectors. I wait some time after injecting so as to allow the spasm which grasps the instrument to subside. I am much indebted to Messrs. Arnold and Sons, West Smithfield, London, E.C., for carrying out my suggestions. The instruments are made of silver.

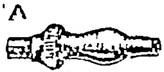

FIG 3

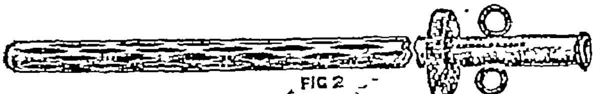

FIG 2

SCALE ABOUT ½

Whilst on the subject of aspiration I may offer to others an aid which has frequently been of good service to me. I refer to drainage of the bladder by means of aspiration, whether this be suprapubic or otherwise. I make use of a resistant indiarubber tube with a tap to connect the catheter to a large bottle, the air of which is occasionally exhausted by a Potain apparatus. The tap is now and then turned so as to aspirate the urine away, thus keeping the bladder empty. I have found this device more effectual than even Cathcart's ingenious plan of syphonage.

Finsbury-pavement, E.C. James MacMunn.

THE FIRST FRENCH CONGRESS OF STOMATOLOGY.

The Société de Stomatologie, wishing to celebrate the twentieth year of its foundation, has decided to organise a Congress of Stomatology in Paris which will be held from August 1st to 5th, 1907. It is stated that this Congress is intended to demonstrate that stomatology is a branch of medicine—a medical and surgical specialty—just as much as is ophthalmology or laryngology, and that it requires from those who practise it a complete knowledge of medicine. The diseases of the mouth, teeth, and jaws, it is urged, are closely related to other diseases and to general pathology, and a correct knowledge of this relation is necessary for all who practise stomatology with all that it includes.

In addition to many papers and demonstrations promised by the leading members of the Société de Stomatologie a number of foreign medical men have promised to take an active part in the proceedings. Several distinguished dentists from America, including Professor Talbot (Chicago), Dr. Latham (Chicago), Dr. Brown (Milwaukee), Dr. Fletcher (Cincinnati), and Dr. Rhein (New York), have already promised to give papers or demonstrations. A museum of all the various models, instruments, pathological specimens, &c., which are of use and interest to the dental surgeon is being formed, and it is hoped that England will also contribute largely to the success of this department. The names of M. Cruet, president, and M. Galippe and M. Redier, honorary presidents, appear on the committee of organisation. M. Chompret, 182, Rue de Rivoli, Paris, is the secretary, from whom all information can be obtained.

Immediately following this congress (August 6th and 7th) the International Stomatological Association, having the same objects, will hold its first meetings and will occupy itself with questions relating to legislation and professional organisation, education, oral hygiene, and international stomatological bibliography. The committee of organisation of this association is formed of one representative from each country and includes several well-known names, such as those of Professor J. Arkövy of Budapest, M. Cruet of Paris, Dr. H. Allaeys of Antwerp, and Professor Eugene Talbot of Chicago. Dr. J. Sim Wallace of London represents England.

Membership of the Congress of Stomatology is open (1) to all members of the Société de Stomatologie de Paris, whether charter or regular members; (2) to all legally qualified medical men practising oral or dental surgery—including, therefore, medical graduates of a French or foreign university or the possessors of the diplomas of the Royal Colleges of Great Britain and Ireland; and (3) to individuals who by reason of their work, knowledge, or attainments may be admitted by the committee of organisation. Meetings will be held in the amphitheatre of the Faculty of Medicine and the proceedings will include four discussions upon stomatological questions; communications on any subject in stomatological science, mechanical dentistry included, may also be presented. Patients, specimens, drawings, casts, and instruments will be shown. The membership subscription is 25 francs. French will be the official language of the congress but Esperanto will be admitted in the discussions; English and German will also be admitted if followed by a French summary of the lecture or discussion.

Medical Defence Union.—The annual general meeting of the Medical Defence Union will be held at the Midland Hotel, Manchester, on Thursday, May 16th, at 4 p.m., to receive the annual report of the council and the statement of accounts, together with the auditor's certificate for the year 1906; to elect three members of council, Mr. J. Roche Lynch, Dr. A. A. Mackeith, and Dr. F. J. Wethered, honorary treasurer, retiring by ballot under Rule 28, but offering themselves for re-election; to appoint an auditor and to fix his remuneration; and to vote for the payment of railway fares as expenses incurred by provincial members of the council attending council meetings.

THE LANCET.

LONDON: SATURDAY, MAY 4, 1907.

The University of London and Medical Education.

THE biennial semi-general election to the Senate of the University of London is a somewhat lengthy proceeding. The vacancies which occur every two years by the compulsory retirement of one-half of the senators are filled partly by nominations of the Crown and by professional bodies, such as the Royal Colleges, and partly by elections under a wider franchise. The teachers who are members of their respective Faculties elect a certain number of representatives, and the graduates, as members of Convocation, choose others. The Crown and the London County Council generally lead off by nominating their representatives in February, while Convocation postpones its elections till the last moment, which is in the first week of May. At the present time therefore the greater number of the vacant posts have been filled and it only remains for Convocation to declare its choice at the elections which will take place next week. Most of the Convocation elections will this year be contested, as was also the case with the elections in the Faculty of Medicine. The interest which is being shown in the present semi-general election is a good augury for the ultimate development of the University. It must, however, be admitted that some of the results already declared as well as some recent results in by-elections are not altogether satisfactory. There is an indication of a temporary ascendancy of reaction against the movement for the conversion of the old examining board into a real teaching University. This was perhaps inevitable, but it is none the less disappointing. The relations of the University to medical education in the metropolis is naturally a subject which has the greatest interest for readers of THE LANCET. It appears, indeed, that questions of medical policy are at the moment being canvassed in other faculties besides that of medicine and may indirectly affect the Convocation elections by graduates in non-medical subjects. At any rate, the standard of medical degrees and the concentration of earlier medical studies are two subjects upon which memoranda and circular letters are being actively distributed.

Our views on these two important questions of policy should be well known to our readers. We have from the first consistently advocated those reforms in the constitution of the governing body of the University which culminated in the complete reorganisation of the Senate six years ago. The conviction that a mere examining board could never be a suitable substitute in this great city for a living, teaching university was the motive force which led after years of struggle to this much-needed change. It was well recognised, however, that the transformation of the machinery of administration was not the end in view but was merely the means of enabling those who knew how to do so to carry reform into effect. The extraordinary cumbersomeness of the new machinery was almost enough to appal the stoutest reformer, and recent electioneering methods have shown how well this complicated mechanism facilitates the attacks of those who sigh for the good old days of intricate examinations, ill-educated candidates, and wholesale rejections. To these admirers of the old examining board a high standard of examination and a valuable university degree can only be indicated by the large proportion of candidates whose education is so faultily conducted that they fail to obtain recognition of their abilities. Any attempt to coördinate education and examination is regarded by such persons as a step in a downgrade competition and leads to a cry that the University is lowering the standard of its degrees. THE LANCET has always maintained that bare justice to Londoners who desire to study medicine demands that the University shall so adapt its tests and its teaching to each other that the industrious student of average ability shall be able to obtain a pass degree in his own city and not be compelled to migrate to the provinces for this purpose. For the reconstituted Senate to adopt any policy which does not ultimately lead to this end would be to fail in its obvious duty to London. The proposition that no lessening of the percentage of rejections can be achieved except by sacrificing the value and reputation of the degrees can only be maintained by those who have no knowledge of what constitutes a university. We do not doubt that the Senate fully recognises its duty in this matter and will press on in its good work of coördinating courses of study and their corresponding examinations, confident that by this means only can it satisfactorily lessen the appalling waste of educational energy indicated by a ridiculously high percentage of rejections. In furtherance of this policy of true university progress we cordially support the candidature of Sir THOMAS BARLOW, Mrs. BRYANT, Dr. CHARLES MARTIN, the Rev. VAUGHAN PRYCE, and Professor SYLVANUS THOMPSON at the forthcoming Convocation elections.

On the question of the concentration of the teaching of the earlier medical subjects in two or three institutions under the direct control of the University we see nothing to change our belief that the decision arrived at by the Faculty of Medicine four years ago was a wise one. Too much importance has, perhaps, been attached by some to the rejection by the Faculty of Medicine at the recent election of its two sitting representatives upon the Senate. It is notoriously difficult at elections to limit the controversy to a single issue and it is obviously undesirable to do so in electing the senate of a university. It is impossible to accept the election of two new senators as a clear indication of the views of the Faculty upon a complicated question to which in the past it has accorded the utmost attention and given the clearest expression of its wishes. Before believing that the majority of medical teachers in London are so indifferent to the best interests of medical education as would be indicated by a blind adherence to existing conditions, we should desire to be assured that any modification of policy was arrived at after as full an investigation of the facts as was given to them three or four years ago. We are aware of no change in the serious financial position of medical education in

London, except such as may have been induced by a slight recrudescence of the old mutual jealousies of competing schools which we are confident will ultimately be replaced by a spirit of scientific comradeship in a common university. Meanwhile, competition is an expensive luxury in the pursuit of which the teachers of medicine cannot hope to receive the pecuniary support of the public. It is only by agreeing to a concentration of their efforts that the two-fold advantage of economy and of public support such as has been accorded to medical education in other cities can be obtained by the metropolitan medical schools. The extravagance of maintaining 10 or more separate schools of anatomy and physiology for the number of students engaged upon these subjects in London is too obvious to need serious argument, and two or three facts stand out which make it, we think, impossible to continue the existing arrangements with any prospect of permanent success. No teacher in any of the earlier subjects of medical education in London receives sufficient remuneration to justify him, unless he has private means, in refusing a professorship in almost any other university in the world. The majority of the teachers of the clinical subjects in London either obtain no remuneration at all or the merest pittance, in striking contrast to the perhaps somewhat extravagant payment received by the physicians and surgeons who taught in the medical schools during the last generation. The buildings and laboratory accommodation in the medical schools of the metropolis are for the most part markedly inferior to similar provision on the continent, in America, and even in the provincial universities of our own country. We yield to none in our admiration of the energy and self-sacrifice of the London teachers and of the splendid results which they have obtained in difficult and disheartening circumstances. But these conditions cannot go on and we are confident that the more seriously the position is studied the clearer it must become to the teachers, as well as to the Senate, that "concentration" is imperative if London is to retain its position as a chief centre of medical education. It is unfortunate that Sir THOMAS BARLOW has stated that in view of the recent Faculty election he will withdraw his support from the Senate's concentration scheme. We do not believe that if Sir THOMAS BARLOW fails to secure election the Senate will relinquish its efforts to improve true education in London, notwithstanding that some of his opponent's supporters seem to desire it. Nor can we believe that the defeat of Dr. J. KINGSTON FOWLER and Dr. J. ROSE BRADFORD after six years' loyal and arduous service will in any way lessen the determination of the majority of the Senate to forward the establishment of an Institute of Medical Sciences on the lines so carefully laid down by the Faculty of Medicine.

Medical Expert Evidence in the United States of America.

RECENT legal procedure in America, in relation as much to medical evidence as to any other subject, may not be expected to furnish this country with any valuable examples to copy. Our New York correspondent tells us that the various strategical moves of the prosecution and defence in the notorious THAW case were supported by expert medical evidence on either side with the result that such testimony has been brought into considerable contempt in the United States. We are not surprised to learn it. But a proposal to change the procedure with regard to medical evidence in contested cases has been made in the State of Maine, which is of genuine interest to all who have experience in Great Britain of the undesirable conflicts of expert testimony which arise in many trials in courts of law. These conflicts are not in the least confined to medical topics, but for some reason or other the public considers that a difference of medical opinion in the witness-box is a clear proof of ignorance or venality, while engineers, chemists, and lawyers may contradict each other over and over again and remain honest if opinionated citizens. The suggested innovation in the State of Maine appears to have been formulated originally by Mr. L. A. EMERY, now Chief Justice of the Supreme Court of Maine, before the State Bar Association of his province, his recommendations having since been embodied in a Bill. The judiciary committee of the State legislature reported adversely to this Bill, but the Medico-Legal Society of New York has interested itself in the matter and is endeavouring to bring its principles before the legislatures of other States after securing authoritative opinions in their favour. The following points constitute a summary of what is objected to in the present situation in American courts: (1) the partisanship of paid medical experts; (2) the payment of large sums of money to medical expert witnesses for services supposed to be rendered by them; (3) the growth of the practice of having expert witnesses present who listen to the evidence of other medical men and are then asked for their opinions upon the evidence thus given; and (4) hypothetical questions put to expert witnesses. These points will readily be understood by medical men who have followed trials in this country in which contradictory medical evidence has been given, although possibly the undesirable features of the system may be more accentuated in the courts of the United States. Barristers also who are sometimes led into making uncomplimentary comments upon the testimony given by "experts" should agree that the partisanship observable is, as a rule, perfectly honest and unconscious, arising out of the manner in which scientific questions are contested in the law courts under a system for which the lawyers and not the expert witnesses are responsible.

The remedy proposed on the other side of the Atlantic consists, as might be anticipated, in giving the court power to appoint independent experts to form opinions, if desired, upon matters in dispute, the first section of the Bill referred to being as follows: "In any case, civil or criminal, in the Supreme Judicial Court or any superior court where it appears that questions may arise therein upon which expert or opinion evidence would be admissible, the court or any justice thereof in vacation may appoint as examiner one or more disinterested persons qualified as experts upon the questions. The examiner at the request of either party or of the court of justice appointing him shall make such examination and study of the subject matter of the questions as he deems necessary for a full understanding thereof, and such further reasonable pertinent examination as either party shall request. Reasonabl[illegible]ll be given each party of physical examination of persons, things, and places, and each party may be represented at such examinations." The remaining sections provide further details of the procedure to be followed, including power given to the court, or to either side, to call the examiner appointed by the court into the witness-box. There is no restriction laid upon the parties calling their own witnesses if they desire to do so, but it is anticipated by those in favour of the proposed measure that the practice of calling witnesses avowedly favourable to the parties tendering them will die out, on account of the disadvantage at which these would be in relation to the independent and official witness. The suggestion of such independent expert witnesses being called in medico-legal cases has been made often in this country and has received the support of important men in both the legal and medical professions. It is to be hoped, therefore, that certain of the American States may be found to give a trial to the innovation proposed. We are ourselves experimenting in a similar direction in the enlarged powers given to medical referees by our latest Workmen's Compensation Act, and it seems possible that very useful results may be obtained by combining experience gathered in two countries, each of which is aware that its previously existing system is far from perfect.

The Accommodation of Hop- and Fruit-pickers.[1]

IN a recent report to the medical department of the Local Government Board Dr. REGINALD FARRAR, one of the medical inspectors to the Board, records the result of an extensive inquiry into the lodging and accommodation of hop-pickers and pickers of fruit and vegetables in different parts of England. He has visited many hop-gardens and farms where strawberry-pickers and pea-pickers are employed, and his report gives a variety of useful information obtained by personal investigation and by discussion with growers, pickers, local sanitary and police officers, missionaries, and others. As a result of these inquiries he is able to indicate practical lines on which rural sanitary authorities *should* proceed in order to deal with the important questions of sanitary administration which arise from the enormous migration of hop-pickers and fruit-pickers which takes place during the picking season. The powers required by local authorities to secure the decent lodging accommodation of hop-pickers and others are to a large extent supplied by the adoption of by-laws such as those formulated by the Local Government Board in its model clauses of 1902. These model by-laws, together with certain alterations and amendments which have since been officially approved, are reproduced in the report. By-laws of this kind appear to have been adopted in the majority of districts concerned, although there are notable exceptions, such as the rural district of Faversham, into which about 9000 "hoppers" migrate during each season.

Dr. FARRAR'S report will strengthen the hands of local authorities in making active use of these by-laws. He shows that many hop-growers have not only provided accommodation which complies with by-law requirements, but in addition have taken trouble to afford their workers rough-and-ready conveniences of different kinds. Plans and illustrations are given of huts, shelters, cooking arrangements, and the like which have been provided at comparatively low cost, and which represent a distinct advance on the conditions which formerly obtained. The growers who have supplied lodging accommodation of a satisfactory kind are usually individuals or companies in a large way of business who can regard such provision as part of their capital outlay. The smaller grower would in some cases find it difficult to follow their example. Dr. FARRAR points out, however, that the hop industry under modern conditions has become profitable only to the grower on a large scale who can afford to practise "intensive" cultivation and scientific methods of drying and is in a position to hold over crops from one year to another. The smaller farmer without capital has now to a large extent been squeezed out of the industry. Hop-pickers may be classified as "home pickers," "foreign pickers"—i.e., persons imported into the district from large towns—gipsies, and casual vagrants. Employment of the habitual vagrant is not encouraged by most growers. A few hop-growers, however, appear to depend almost exclusively on tramps for picking, while the vagrant supplies a large part of the labour required during the pea-picking season in Worcestershire. Where "professional" vagrants are aggregated in a district they are invariably a source of great annoyance, nuisance, and even serious danger to the inhabitants. In Upton-on-Severn during the pea-picking harvest it is reckoned that the expense entailed by police precautions and extra casual ward accommodation almost counterbalances the profits of the pea-picking industry to the district. Dr. FARRAR points out that the gipsy class of pickers, nomads dwelling in their own vans and tents, contrast favourably in most respects with the habitual vagrants. They are good pickers and in general fairly orderly, though sometimes quarrelsome. Their presence is occasionally objected to by farmers on account of their pilfering tendencies, but from a sanitary standpoint does not, as a rule, afford ground for serious complaint.

As regards the most important class of pickers, the "foreigners" or casual hands from the large towns, Dr. FARRAR, as already indicated, is able to point to a general tendency to improvement in their conditions of lodging, especially in certain hop-gardens. He gives illustrations, however, of insufficient or filthy accommodation for sleeping, absence of water or facilities for cooking, and other objectionable conditions for which neither the short period of employment nor the class of people employed should be accepted as an excuse. Attention is also drawn to the way in which married couples, single men, and girls are often herded together indiscriminately under the same roof or in the same tent, and to the gross overcrowding which is liable to take place in tents and huts, especially on Saturdays and Sundays, when the hoppers have week-end visits from friends in town. There would often be great advantage in the provision of camp latrines. The amount of supervision exercised by officers of the sanitary authorities concerned varies greatly; in several districts is done by certain inspectors of nuisances, but in others the inspector does not regard this supervision as part of his duty. In one of the most important hop-growing districts Dr. FARRAR found that the local inspector had chosen the hop-picking season as the time for taking his annual leave. Much good may be done by inspectors who keep an eye on the quality of the food, particulary the fish, which is taken to hop-pickers by hawkers and others; knowledge on the part of dealers that unsound food is liable to seizure does much to insure a proper food-supply. The report makes most interesting reading and lets a flood of light in upon a somewhat dark and untrodden path in public health.

Annotations.

"Ne quid nimis."

THE PROVISION OF SELF-SUPPORTING SANATORIUMS FOR THE WORKING CLASSES.

ON Tuesday, May 14th, a dinner will be held at the Hotel Cecil in support of the National Association for the Establishment of Sanatoria for Workers suffering from Tuberculosis. H.R.H the Prince of Wales will take the chair and the long list of stewards contains many influential and distinguished names, which include the majority of the foreign Ambassadors and Ministers in London. The scheme was founded under the ægis of the Hospital Saturday Fund and has for its object the coöperation of friendly societies, trade unions, and other organisations to establish self-maintaining sanatoriums for workers. The board includes representatives of many sick and friendly societies of high standing and intends to make the sanatoriums entirely self-supporting when they have been built by the subscriptions of the charitable. These societies comprise about 3,000,000 workers, irrespectively of their wives and families. One concrete example will well illustrate the scheme. In the first or model sanatorium at Benenden in Kent, of which the first 30 beds were opened on March 4th, provision will be made for 200 beds, and of these the Postal Federation has guaranteed to support 25, over 40,000 of its members having undertaken to subscribe 2s. a year for that purpose. Other bodies of workers are making provision to support other beds. A special feature of the scheme is that whilst the bread-winner of the family is receiving treatment in the sanatorium the wife and children will receive the full amount of the sick pay which he would have received under the old *régime*, this being provided for by the self-imposed extra levy on the members of the society. Preference is to be given to early cases for treatment in the sanatoriums and it is proposed to provide such light employment for patients as the medical officers may deem advisable. This scheme constitutes the first serious attempt to emulate the German system of workmen's insurance. It is true that it differs vastly from that measure in not being compulsorily enforced upon the people, but the large number of workers whom it will affect and the soundness of its provision for their benefit bring it within comparison of the great Bismarckian scheme. It entirely obviates the pauperising tendency that many people see in our present system of relief, and if it is to be successful will fill an urgent national want. It is necessary, however, for the committee to appeal to public benevolence to build and to equip the proposed sanatoriums, for the affiliated societies are prevented by their constitutions from making more than ordinary donations towards the acquirement of sites and building. Money could hardly be given with a better assurance of its utility than is afforded by the objects of this National Association, and we wish it both on the occasion of this dinner and afterwards a full measure of success in attaining those ends. The value of the sanatorium system of treating tuberculosis is to some extent on its trial, while expert opinion is also not unanimous as to the best method of constructing the buildings. But no one doubts that sanatoriums are of great benefit to certain sufferers, while those as yet in existence are for the most part placed by their pecuniary demands out of the reach of working men. It goes without saying that the guiding principle of the self-supporting sanatoriums will be the practice of the utmost economy commensurate with efficiency. Anything like unnecessary extravagance must ruin the scheme.

LEAD AND ARSENIC IN TARTARIC ACID, CITRIC ACID, AND CREAM OF TARTAR.

AN inquiry was instituted some time since by the Local Government Board in regard to the contamination of tartaric acid by lead and arsenic in consequence of representations which had been made to the Board that certain manufacturers and importers refused to give any guarantee of purity in respect to lead and arsenic in the tartaric acid which they sold. The obvious result of this singular attitude might be that tartaric acid containing excessive amounts of these impurities might find its way into the market for the purposes of food or medicine. The matter was clearly one calling for settlement, since, as is well known, deleterious effects are liable to result from the continued ingestion into the human system of comparatively small quantities of lead and arsenic. The Local Government Board subsequently appointed Dr. A. W. J. MacFadden to obtain some information regarding the alleged contamination and in a report just issued he has included also some observations as to a similar contamination of citric acid and cream of tartar. It appears from the tables published in this report that in 15 out of the 30 foreign samples of tartaric acid examined the amount of lead present did not exceed 0·002 per cent.; three samples contained a percentage of lead over 0·002 but below 0·003; in 12 samples the lead exceeded 0·003 per cent., the highest figure being 0·0062 per cent. Notable quantities of arsenic were found in several of the samples of Spanish tartaric acid, but with the exception of a sample from Italy and two Austrian samples the other specimens were reported to be either free or as containing not more than one-hundredth of a grain per pound, the limit fixed by the Royal Commission on Arsenical Poisoning. In regard to cream of tartar the proportion of lead was in no case more than 0·0033 per cent., and in 11 out of the 15 foreign samples examined the amount of lead did not exceed 0·002 per cent. Only one sample of cream of tartar contained arsenic in amount exceeding the limit of one-hundredth of a grain. In the five samples of tartaric acid and cream of tartar of home manufacture the lead in no case exceeded 0·002 per cent., while arsenic was not found in any of them. It is concluded that in view of the uses to which tartaric and citric acids and cream of tartar are put, recognised definitions of objectionable impurities are needed for application by manufacturers, chemists, and analysts and for use by importers and merchants selling these materials for food and drug purposes. The requirements of the 1885 and 1898 editions of the *British Pharmacopœia* do not, it is claimed, in the case of either tartaric or citric acid serve the purpose of the *Pharmacopœia* as regards contamination by lead and arsenic. General adoption of definite numerical limits of impurity as regards these metals in tartaric and citric acid would seem to offer a more satisfactory basis for trade guarantees and for analytical practice.

Looking to all the circumstances, Dr. MacFadden thinks that having in view the quantities in which tartaric and citric acids and cream of tartar are consumed in food, drinks, medicines, and so on, it is reasonable to conclude that minute amounts of lead or arsenic below 0·002 per cent. and 0·00014 per cent. respectively would not be sufficient to justify their condemnation. Lead appears to owe its origin to the lead-lined vessels used in the manufacture of tartaric and citric acids, while arsenic is most probably derived from the mineral acids used in the process of their manufacture.

AN OBJECT-LESSON FROM AMERICA.

WE have before us the first annual report of the "Social Work permitted at the Massachusetts General Hospital," which we have read with pleasure and interest. It contains a most practical attempt to deal with a difficulty the existence of which must have been realised by every physician or surgeon attached to the out-patient department of a hospital. The gist of the work with which the report deals is neatly expressed in the first paragraph. "In most hospitals there occurs many times each year a scene not unlike that described in 'Alice in Wonderland.' '*Have some wine,' said the Hatter. 'I don't see any wine,' said Alice. 'There isn't any,' said the Hatter.*' Without any sense of the humour and pathos of the situation we say (in substance) to many patients: 'Take a vacation,' or 'Get a job,' or 'Get a set of teeth.' There is none in sight and no means of getting any. What do we do then? We pass cheerfully on to the next patient." Now it is true that this recurrent difficulty is partly met by the various Samaritan funds and surgical aid societies in connexion with our hospitals, but any one who has known of an unfortunate with one leg amputated painfully dragging himself about month after month to collect the many letters necessary to permit such an organisation to make good his deficiency will testify that our present system is far from perfect. The Massachusetts Hospital has been fortunate in enlisting the sympathies of a large body of voluntary lady workers who have organised a system of social relief work the scope of which, so far as we know, finds no parallel in the hospital life of this country. There are many channels into which their enterprising help has been turned which may be classified as follows: (1) Tuberculosis—the proper distribution of tuberculous patients into "classes" for further treatment; (2) inquiry into the hygienic conditions of patients and their proper instruction therein; (3) the instruction of mothers in infant feeding and preventive work with delicate children *in their own homes*; (4) the provision of vacations, outings, convalescent homes, and change of work for those in need of them; (5) the care of unmarried girls, pregnant, morally exposed, or feeble-minded; (6) the after-care of cases discharged from the wards; (7) work as a distributing agency of deserving cases to proper charitable institutions, insuring the maximum help for them with the minimum delay and trouble; and (8) "almoner" work, i.e., investigation of patients' financial condition. It is noteworthy that none of these schemes include the direct monetary assistance of patients, which is considered to be beyond the scope of the organisation, but all of them necessitate for their success the very diligent personal efforts of the workers. The method adopted is for the general secretary of the work to be present in the out-patients' hall to whom the presiding physician or surgeon may refer any case whose social condition requires investigation or whose requirements fall under one of the above heads. A record is kept giving the medical and "sociological" diagnoses, the disposition of the case and the outcome of it after one, three, and 12 months, and so on. If, for instance, the patient is suffering from tuberculosis steps are taken to get him admitted to a proper sanatorium, or if that be impossible he is attached to one of the "tuberculosis classes" held under medical supervision in different centres of the city where the open-air system of the disease is fully taught to him by voluntary workers who also regularly visit his home to see that their lessons are being properly carried out. This last office is rightly considered one of the most important of the system, not only for the treatment of tuberculosis but of other diseases also; the out-patient physician must only too often feel that his careful instructions in hygiene are but wasted breath when they have merely evoked the plaintive request, "Aren't you going to give me a bottle of medicine, doctor?" The provision of a living and intelligent link between the consulting room and the home is the most striking feature of the system, and given good workers should more than double the value of out-patient treatment. The remaining heads call for less comment, but it is interesting to note a branch of "rescue work" and also a clearing-house system to distribute necessitous cases to other suitable charities. The scheme has evidently been most enthusiastically organised, and although it is only yet on probation during its first year 684 new patients have been dealt with and 857 visits paid to old patients. The work thus auspiciously begun has our best sympathy and we shall follow its development with interest. If any large and practical measure of success appears to follow directly upon it we hope that the Massachusetts General Hospital will communicate the results to the lay press in this country as well as in America. A movement of this sort concerns the public most deeply. Only with the support of the public can it be organised on really inclusive lines, and then (be it remembered) entire devotion on the part of the workers will have to be given to insure success.

THE CITY OF LONDON AND THE FEEDING OF INFANTS.

IT is a very healthy sign of the times that at last public attention is being directed to the terrible scandal of preventable infant mortality and by consequence to the measures necessary for its reduction. Of these the provision of a pure milk-supply and the proper feeding of infants are incomparably the most necessary; the former is engaging the attention of our legislature and the latter is being brought more prominently before the public by its medical advisers. There is no doubt that a more scientific and widespread knowledge of the principles that underlie the proper rearing of infants is possessed by our profession as a whole than was the case a few decades ago. The ignorant mother or nurse has less licence to wreak her nefarious, if well-meaning, designs upon the infant's stomach—at least, where the family practitioner has a fair opportunity for veto; but, unfortunately, the great majority of babies who are exposed to the deadly perils of the dirty feeding-bottle and unassimilable "food" never pass under medical supervision. To reach the mothers of this class the medical officers of many boroughs have lately issued circulars containing clear and concise directions for the preparation of meals for infants, qualified by an authoritative statement of the superiority of breast-feeding during the first nine months. These gospels of hygiene take the form both of cards for hanging up in public places and pamphlets intended for broadcast distribution; one of the former, prepared by the medical officer of health of the City of London, lies before us and is an admirable example of what such a manifesto should be. Ample instructions both for breast- and bottle-feeding are given, including a much-needed warning against dummy "teats." The only rule with regard to which we would suggest a modification is this, "Always taste the food before giving it to the child," which might lead an ignorant and possibly diseased woman to take a preliminary suck at the bottle. We should prefer to see, "Taste a spoonful of food from the vessel in which you mix it before giving it to the child." The instructions given for the dilution of milk are in accordance with the proportions that are usually taught in this country. It will be interesting to note whether the recent English translation of Budin's splendid work on the nursling, in which he advocates a dietary of good and well-boiled whole cow's milk, will lead to such an adoption of his method in this country as will justify its appearance in some future manifesto for the instruction of the public of the City of London or elsewhere. The present one includes a few wholesome rules of hygiene for both mother and child.

BREAKFAST FOODS.

Professor Robert Harcourt has contributed to the *Journal of the Society of Chemical Industry* of March 30th a valuable paper on the chemical composition, digestibility, and cost of several wheaten and oaten products that have been placed on the market under the names, "breakfast cereals" and "breakfast foods." According to the claims made for some of these foods they are not only perfect foods in a condensed form but they are also brain tonics and possess a variety of wonderful virtues. Professor Harcourt ruthlessly looks below the surface of mere newspaper "puffs" and shows by a series of analyses how little these extravagant claims find justification in fact. The various breakfast foods may be roughly divided into four classes: 1. The old forms of uncooked granulated oatmeal and the wheat farinas. Foods of this class are served after cooking either for a short time or for several hours. 2. Partially cooked rolled and flaked grains. In manufacturing these foods the grain is softened by steaming and then rolled and dried. In this way the food is slightly cooked and may be subsequently prepared for the table in a very short time. 3. Cooked foods—e.g., shredded wheat, which may be served at once without further cooking. 4. Malted foods—e.g., Force and Grape Nuts, which are supposed to be both cooked and partially digested. Professor Harcourt examined the following breakfast foods: Granulated and rolled oats, Quaker Oats, wheat farina, wheat germ, and rolled wheat, flaked barley, cornmeal, Orange Meat, Force, Norka, Malta Vita, Grape Nuts, Canada Flakes, shredded wheat, and rice flakes. Of these, the oatmeals and Norka, an oaten product, contain the most proteins and fat, while all the other foods are richer in carbohydrates. From a consideration of the data set forth in the paper and of the number of heat calories these foods produce when burned, the conclusion is drawn that the oaten products have the highest nutritive value. The much advertised prepared breakfast foods have only a very slight advantage over the ordinary wheaten farinas. Experiments were made to determine the digestibility of these different foods by ascertaining the quantity of protein, fat, and carbohydrates in the food eaten and in the fæces, the differences being regarded as the amount digested. Healthy young men were taken as subjects and each experiment extended over a period of four days. According to these results the wheat germ is more fully digested and absorbed than any of the other foods. The protein of all the foods examined is less completely assimilated than the other constituents. This is particularly true in the case of Force. It is also worthy of note that the carbohydrates of Orange Meat, Force, and Norka are not so fully assimilated as those of the other foods. The results, as a whole, indicate that the expensive prepared breakfast foods are not more completely digested and assimilated than the wheaten farinas and rolled oats or even than the old forms of granulated oatmeal. Calculations were then made as to the food value of the digestible matter obtained from a given money value of each of the foods examined. It was found that cornmeal is the most economical of these foods, the oatmeals take second place, and the wheat germ occupies the third place. Oatmeal and wheaten farina in packages are twice as expensive as in bulk. The pre-digested foods are very much more expensive; thus, Force costs more than four times as much as granulated oats. Experiments were made to determine the influence of cooking on the solubility of these various foods. Rolled oats and wheaten farina were cooked for different lengths of time, when it was found that the wheatmeals are more readily rendered soluble by heat than the oatmeals. Thus, after 20 minutes' boiling the aqueous extract of wheaten farinas contained 27·4 per cent. of soluble matter, while the extract of the oatmeals contained only 14·95 per cent. Rolled oats and wheaten farina were then boiled for different lengths of time, from 20 minutes to eight hours, and the products were eaten by different subjects in order to determine the digestibility of the foods so treated. The results showed that the length of time during which the food is cooked does not very materially influence the percentage amount assimilated. It is possible that less energy may have been expended in digesting the foods that were cooked for the longer times, but no figures could be procured on this point. From all the data presented it is evident that cornmeal, rolled oats, and the farinas, especially if bought in bulk, are the most economical breakfast foods. It is, however, true that these foods do not agree with everyone and that the pre-digested foods may be useful for those people who have difficulty in digesting starch. But the intelligent housewife who needs to consider economy will do well to continue to use the old forms of breakfast foods, except in individual cases in which difficulty is found in digesting them.

METROPOLITAN FEMALE SANITARY INSPECTORS.

A RECENT return shows that of 28 metropolitan borough councils 22 now employ women sanitary inspectors or health visitors. Those which are not yet included in this list are Stoke Newington (which is a residential district), Bermondsey, Deptford, Greenwich, Shoreditch, and Stepney. The last two names are somewhat surprising as they form a considerable area of "the workshop of London." The Stepney borough council has just declined to appoint a lady sanitary inspector, as it had been petitioned to do by the Stepney Visitors' Association. Islington and Southwark have had such officers on their staffs for more than ten years and in many cases the strength of this element has been increased, in several cases more than once, so that 14 borough councils now employ more than one woman in this work. Battersea and Hammersmith have a health visitor only, the whole of whose salary they find; in the case of sanitary inspectors the London County Council bears half the expense. The salary of these officers varies from £100 to £185 per annum. The chief duties allotted to the office are the inspection of workshops where female labour is wholly or partially employed, the inspection of the homes of out-workers, especially relative to inquiries as to notifiable and non-notifiable infectious diseases, the inspection of small laundries where mechanical power is not used, the inspection of rooms alleged to be verminous, of the kitchens of eating-houses and restaurants, and also of underground public sanitary conveniences. Most of these women have also more or less defined duties appertaining to health visiting, notably with reference to the reduction of infant mortality, to the instruction of mothers of families in health principles, and to the inspection of homes in which non-notifiable diseases have occurred. It was reported that in Stepney there are 191 workshops where female labour only is employed 1732 workshops where men and women work, and 3240 places where home-work was performed during the year 1906. In addition to the above official staff there are several voluntary associations which assist in health visiting, working more or less under the supervision of the local medical officer of health.

OPERATIVE TREATMENT OF CONSTIPATION.

Eleven patients illustrating the results of the operative treatment of chronic constipation were shown on April 28th at Guy's Hospital. The occasion attracted many medical men. The patients were closely questioned and carefully examined, especial interest being shown in regard to the diet taken by them which in all cases was found to be the ordinary daily food of the class of life of the patient. Mr. W. Arbuthnot Lane's reasons for short-circuiting the intestine and removing the cæcum and large bowel in these 11 cases, consisting of ten women and one man, were the sufferings of the patients from continued loss of flesh and pain resulting in total inability to work, partly due to intestinal stasis and partly due to toxic influences. In some instances the operation had been performed three years ago and in all marked improvement in health and strength was strikingly exhibited, the condition of rapidly progressive degeneration being replaced by one of physical capacity and the general appearances of health.

LOATHSOME BED STUFFING.

We make no apology for returning to this subject, as in our opinion the attitude of the Government in regard to it is very unsatisfactory, while a distinct menace to the public health is being allowed to exist with no organised attempt whatever to suppress the evil. We have received from many quarters complete endorsement of the remarks which we have made from time to time and we have abundant reason for believing that the information supplied to us is absolutely correct. The latest communication is convincing and contains singularly unwholesome facts. "The awful filth that finds its way into beds and mattresses is," says our correspondent, "appalling; rags of the most filthy kind and old carpets stinking with dirt are torn up by a machine known as 'the devil.'" After the heavy grit is shaken out the so-called wool is sent to the bedding manufacturer to be put into beds and mattresses and in many instances these are labelled and sold as "sanitary bedding." There cannot, of course, be the least objection to the use of such material for this purpose provided that it is thoroughly washed and sterilised. We understand, however, that this desirable process would add to the cost by about 2*s.* for each bed and rather than pay this extra amount for a sanitary and clean mattress a stupid section of the public would sooner run the risk of having an offensive bed to lie upon if not one which may very possibly reward their pigheadedness with disease. And manufacturers sell these mattresses realising full well the penalties which the buyer is likely to incur and yet they are powerless to stop it because if they insisted upon an extra charge of 2*s.* for a cleaned mattress their business and custom would be threatened with extinction. "20 years ago," writes our correspondent, "I made no flock but what was washed and sterilised, but to-day, I am sorry to admit, I am compelled to do as others do and make the filthy stuff to compete and hold my own, *for* there are many manufacturers who have no washing plant, and probably 80 per cent. of all beds and mattresses are made from the rags torn up and used as filling in their dirty state." This evil trade does not only apply to bedding, for there are reasons for believing that what is the most magnificent upholstery on the surface in the shape of velvets, sateen, and tapestry may, after all, be sheltering a loathsome stuffing. The public, or that section of it which cares for these things, would do well to regard this matter seriously, and it is easy enough to ascertain by a simple test whether the character of this material is objectionable or not. If a portion of the material be taken out of the case and placed in a basin containing some boiling water and stirred up there will be an unmistakeably offensive smell evolved if the material is unscoured and unfit for bedding, while the water will become dirty-coloured. Often, however, the stuffing is so palpably bad that such a test is quite superfluous. Surely some system of control should be established by the Government without any delay which will put an effectual end to this infamous disregard for cleanly dealing and common hygienic demand.

THE FOURTEENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

At this Congress, which is to be held in Berlin from Sept. 23rd to 29th, the exhibition will be a prominent feature. Scientific institutes, as well as State and municipal authorities, together with private firms, are taking an active part in the preparations for it, and it is hoped that the exhibition will afford a general view of the present state of hygiene from both a theoretical and practical standpoint. The methods of combating infectious diseases (especially colonial and tropical diseases), State and municipal hygiene (especially the care of infants), the providing of good drinking water, the removal of waste, and the hygiene of schools will be represented in an exhaustive and interesting manner. Considering the great importance of hygiene as regards both private and public life it has been resolved to keep open the exhibition, which is to be held in the "Reichstag," after the closing of the Congress up to the end of September. Those interested will have full opportunity to make themselves acquainted with this department of medicine, the progress in which has had a notable effect with regard to the diminution of the general mortality and the considerable advance in the average age limit during the last ten years.

THE BACTERIOLOGICAL DIAGNOSIS OF TYPHOID AND PARATYPHOID FEVER.

In a research carried out in the Hygienic Institute in Kiel Dr. R. Müller and Dr. H. Graf[1] were able to find either typhoid or paratyphoid bacilli in the clot of the specimens of blood sent for Widal's reaction in eight out of 11 examinations, a result all the more surprising since it has been generally supposed that the bacilli in the clot and serum of such a specimen are killed by the bactericidal action of the blood serum. To control these observations Dr. O. Kurpjuweit[2] examined all the specimens sent to the bacteriological laboratory in Saarbrücken from Jan. 11th to March 14th, 1906—in all 294. The method adopted was that after the serum had been pipetted off and used for the Widal test the blood clot was spread by means of a glass spatula upon a litmus-lactose agar plate, as used in the v. Drigalski-Conradi method. In a certain number of the cases the blood-stained serum was also spread out upon plates in a similar manner. In 12 cases a positive result was obtained from the blood clot, a growth of typhoid or paratyphoid bacilli appearing, while in the case of the serum the results were uniformly negative. Of the remaining 282 trials, 194 proved to be from cases *not typhoid* fever. The number of colonies obtained from the small quantity of clot used (from 0·1 to 0·15 cubic centimetre) was usually small, varying between one and 21, but in one case of paratyphoid fever there were about 1600. Dr. Kurpjuweit concludes that although the culture of the clot does not give such generally good results as those of cultures made from the blood itself, the urine, or the fæces, yet in some cases it may show the presence of bacilli when they are overlooked by the other methods, so that in virtue of its simplicity it is worth while doing in every case where a Widal reaction is tried. He further quotes some observations made since his own were completed by Dr. Fornet,[3] who by means of an improved technique succeeded in growing the organisms 14 times out of 19 examinations of the blood clots in the capillary tubes sent for the Widal reaction. The method which he adopted was to put about five cubic centimetres of fresh ox bile in test-tubes, which were then sterilised in a steam oven or by boiling in water. The clot in the Widal tube was placed in one of these tubes after it had cooled and it was closed with cotton-wool in the usual way and put in the incubator for the night. On the next day a large Endo's or v. Drigalski-Conradi plate was inoculated from the bile tube. The effect of the bile is explained by the suggestion that it dissolves the blood and sets free the organism. By this means it is possible to establish the diagnosis of typhoid or paratyphoid fever in the first few days of the disease, at a time when Widal's reaction is likely to be slight or negative and when the bacilli are usually not able to be grown from the fæces. The method is simple of execution and, judged by the reports given of it, seems likely to be a valuable addition to our means of diagnosis.

UNCINARIASIS IN PORTO RICO.

IN the *Boston Medical and Surgical Journal* of April 4th Dr. B. K. Ashford and Dr. W. W. King have published an important paper on uncinariasis in Porto Rico. The parasite of the disease, the necator Americanus or uncinaria Americana, belongs to the same family as the ankylostoma duodenale and affects man in a similar manner. Uncinariasis in Porto Rico is not only interesting from the medical standpoint but in consequence of its frequency furnishes an all-important social and economic problem. 70 per cent. of the 750,000 inhabitants suffer, in greater or less degree, from the infection and from 5000 to 7000 annually succumb to it. As in ankylostomiasis, anæmia results; the hæmoglobin amounts on an average to from 40 to 45 per cent. The disease has been misunderstood and attributed to various causes, such as malaria, starvation, climatic influences, and so on. The manner in which the worm invades the human body is now definitely known and constitutes one of the marvels of pathology. As has been shown recently by Looss in the case of ankylostoma duodenale, under proper conditions of temperature and moisture larvæ develop from ova in the fæces of the host. They penetrate the bare skin of the feet of the natives, enter the veins, are carried in the circulation to the right heart and pulmonary artery, to be arrested in the small vessels of the lungs. They break through into the alveoli of the lung, ascend the bronchial tubes and trachea, descend the œsophagus to the stomach, and pass into the upper part of the jejunum, their favourite feeding ground. Dr. Ashford and Dr. King have not only experimentally confirmed this mode of infection but are able to state that it is the only way in which the worm enters the body. The theory of inhalation of infected dust does not merit consideration, as drying kills the larvæ. The disease is always acquired from contact of the bare skin with mud or muddy water and is termed by the natives "mazamorra" (ground-itch). From some minutes to half an hour after standing with bare feet in infected places itching begins. In a day the part becomes covered with papules, which later become vesicles. The following experiment was performed by Dr. Ashford and Dr. King. Fæces laden with the ova of uncinariæ were mixed with earth and water in a dish and placed in the shade. On the fourth day larvæ were very plentiful; the majority appeared to be dead, while some moved slowly. The dish was then left slightly tilted overnight and on the fifth day the larvæ which had collected at the lowest level apparently were dead, while those in the damp mud were very active. On the eighth day the hair was clipped from the back of a guinea-pig four days old and a poultice made with the mud, in which the larvæ were still active, was applied for half an hour. Then the spot was cleansed and rubbed with absolute alcohol. Five minutes after application of the mud the animal showed a desire to scratch. The same application was made on the two following days. On the third day of the experiment the animal seemed well and no dermatitis had developed, but it died in the night. At the necropsy one lung was found solid from effusion of blood and the other was filled with dark red spots. One of these spots was excised and examined under the microscope. Ten encapsuled very active larvæ were seen. They seemed to be so strong as to overcome all obstacles, breaking up the lung wherever it obstructed them. The intestines were normal. An important observation made was that in uncinariasis not the slightest trace of blood can, as a rule, be detected in the fæces. The anæmia cannot therefore be explained by hæmorrhage. As Looss has shown for the ankylostoma duodenale, the lesion produced is practically confined to the mucosa of the intestine. The worm draws this into its mouth, denuding it of epithelium which seems to be its food. Albumin and casts, hyaline, finely granular, and fatty, are commonly found in the urine. The prophylaxis is very simple—the wearing of boots. Treatment consists in administration of beta-naphthol. But in consequence of the condition of the kidneys it should be given carefully.

FESTIVAL DINNER OF THE MIDDLESEX HOSPITAL.

WE have received a letter from the chairman and treasurers of the Middlesex Hospital calling attention to the festival dinner that is to be held under the auspices of H.R.H. the Duke of Connaught at the Prince's Restaurant on May 10th next. It had been intended to hold this gathering during last year but unavoidable circumstances led to its postponement. There is no argument needed in pressing the urgent claims of any large London hospital on the notice of our readers and indirectly through them on that of the larger public whom they may be able to influence. The stability of the Middlesex Hospital finance is no greater than that of other general hospitals, only 15 per cent. of the £40,000 annually necessary for its upkeep being derived from invested property and 35 per cent. from the efforts of a limited number of charitable persons and the various hospital funds. The remaining £20,000 depends on bequests and intermittent charitable contributions from the public. The hospital has a record of 160 years' service to the poor and occupies a central position which, although it borders on a district of great commercial and personal wealth, yet is actually surrounded by a network of poor and densely populated streets; on the larger charity of the former area the latter has undoubtedly a strong claim; the necessity of the hospital in its present site is unassailable as is proved by the 4000 in-patients who yearly receive its benefits. One special feature that strengthens its claim on the sympathies of a very large number of people is the special provision of accommodation made under a bequest in 1792 for the treatment of necessitous patients suffering from cancer "during the remainder of their lives." We need hardly remind our readers that to the cancer wing is attached a research department in the laboratories of which much systematic and useful work has been, and is being, done to throw light on the dark mysteries of this terrible malady. On all grounds, then, we support the special appeal that is being made on the occasion of this festival dinner; those who wish to express their sympathy with its objects in a practical form are asked to send their subscriptions and donations to Messrs. Coutts and Co., 440, Strand; Messrs. Parr's Bank, 1, Cavendish-square, W.; or to the secretary at the Middlesex Hospital, Mortimer-street, W.

EPIDEMIC CEREBRO-SPINAL FEVER.

GLASGOW and Belfast still continue to be the chief centres of the epidemic of cerebro-spinal fever. In the former city the weekly report issued on April 26th showed that there were at that time 114 patients under treatment. In Scotland during the week ended April 27th there were 26 deaths from the disease registered in Glasgow, 8 in Edinburgh, 2 in Leith, and 1 in Dundee. In Belfast during the week ended April 25th there were 36 fresh cases notified and 27 deaths, making since the commencement of the epidemic in Belfast a total of 337 cases with 227 deaths.

GERMAN CONGRESS FOR THE PREVENTION OF VENEREAL DISEASES.

THE Third Congress of the German Society for the Prevention of Venereal Diseases will be held in Mannheim on May 24th and 25th. At 8 P.M. on May 23rd there will be a reception (*Begrüssungsabend*) either in the exhibition or in the Rosengarten. On the 24th, at 8 P.M., the members will dine in the Park Hotel. Applications for dinner tickets (costing 5 marks) should be made as soon as possible either to Dr. Heinrich Loeb, Mannheim P. 7.23, or to the offices of the society, 105A, Potsdamerstrasse, Berlin W. 35. The meetings of the Congress on May 24th and 25th will be held in the Rosengarten from 9.30 A.M. to 12.30 P.M. and from 3 to 5 P.M. The official discussions will deal chiefly with the explanation of sexual questions to children and young persons, and on this subject there will be eight speakers, of whom the first three will be Dr. A. Blaschko, Professor Fr. W. Foerster, and Frau Krukenberg; Herr Köster will discuss literature for the young and Professor Eulenburg and Frau Adams-Lehmann will introduce the subject of "Sexuelle Diätetik." The meetings of the Congress will be public. Anyone may attend and take part in the discussions. Members of the Congress pay a subscription of 10 marks and are entitled to take part in the voting and to receive the Transactions.

THE PREPARATION OF INFANT'S AND INVALID MILK FROM COW'S MILK.

A SOMEWHAT novel method of preparing from cow's milk a modified milk which approximates to the composition of human milk has recently been proposed by Dr. Szekely, chemist to the Hungarian Government. The process is based on the discovery that carbonic acid gas under pressure separates not only the casein but also part, if not all, of the calcium phosphate of cow's milk. The fresh milk under treatment is first heated to 58–60° C. and then poured into a closed cylinder connected in its turn with a cylinder containing carbonic acid gas. The gas is forced into the cylinder containing the milk until the pressure is from 25 to 30 atmospheres. After a time the separation of the casein is said to be complete, and it separates as a spongy mass, a clear pure whey remaining. With the casein is also a large proportion of the salts and more particularly phosphate of calcium. The whey shows the following average composition: Protein, 0·60 per cent.; milk sugar, 4·50 per cent.; and salts, 0·55 per cent. This accords with the composition of cow's milk the casein of which has been removed by Pukkal's clay filter. An important statement in regard to this whey is that it retains the active enzymes of raw untreated milk. It is further claimed that carbonic acid under pressure destroys tubercle bacilli. Pasteurised cream (65°–70° C.) to which the requisite amount of sugar has been added is then put in with the whey and the infant's milk so obtained is bottled ready for use. To 50 parts of whey 49 parts of pasteurised cream are added containing about 9 per cent. of fat and 1 part of milk sugar. The composition of the milk is stated to be as follows: Fat, 4·50 per cent.; casein, 1·50 per cent.; albumin, 0·50 per cent.; milk sugar, 5·45 per cent.; soluble salts, 0·55 per cent.; and insoluble salts, 0·08 per cent.

THE *Department of Public Health of Queensland* in a bulletin dated March 23rd states that a case of bubonic plague, No. 27 in the series, the patient being a male, aged 48 years, was reported from the General Hospital, Brisbane, on March 17th. A fatal case of plague reported after death occurred at Townsville on March 17th. The patient was a man, aged 33 years. There are no further developments at Port Douglas. As regards the Mauritius a telegram from the Governor, received at the Colonial Office on April 26th, states that for the week ending April 25th there was 1 case of plague and 1 death from the disease. A telegram from the Acting Governor of Hong-Kong, received at the Colonial Office on April 29th, states that for the week ending April 27th there was 1 case of plague and 1 death from the disease.

THE death is announced of Professor Albert Ritter von Mosetig-Moorhof, extraordinary professor of surgery in the University of Vienna, the eminent Austrian surgeon. The telegrams which have been published, however, show a marked discrepancy as to the details surrounding the sad event. Professor von Mosetig-Moorhof was well known for his introduction of the use of iodoform for packing cavities in bone.

WE are asked to remind candidates for the Radcliffe prize in the University of Oxford that they should send in their memoirs to the Registrar's office on or before June 1st next. No memoir for which any University prize has already been awarded will be admitted to competition for the Radcliffe prize.

Mr. William Wright, *M.B.*, *D.Sc.*, *F.R.C.S.*, will deliver three lectures on the Prehistoric and Early Historic Inhabitants of England in the theatre of the Royal College of Surgeons of England on May 6th, May 8th, and May 10th, at 5 o'clock P.M.

THE death is announced of Dr. Edward Markham Skerritt, senior physician to the Bristol General Hospital. We hope to give particulars of his career in a future issue.

"SOCIALISM AND THE MEDICAL PROFESSION."

AT a meeting of the Fabian Society held at Essex Hall, Strand, London, on April 26th, Mr. F. Lawson Dodd read a paper on Socialism and the Medical Profession. He commenced by saying that before the democracy would be fit to undertake its widest possibilities education would have to be organised in its service, and with the organisation of education should come the organisation of the medical profession. Both inside and outside that profession there was at present dissatisfaction with the conditions of medical service. The want of system was, however, but a temporary phase in the history of the profession which showed three stages of progress. Having its origin in the mysterious it evolved by various steps to the ecclesiastical period, when medicine was in the hands of the Church in the Middle Ages. This was followed by the commercial or guild system, when the healing art was practised by smiths and barbers. From this point development had taken place, until there were signs that a third stage, the stage of a State medical service, was approaching. The immense advance of science and the work of Wakley in founding THE LANCET and of Sir John Simon were the prominent factors in the movement towards State interference and control of medical service. The first step was the Act of 1858 which by a system of registration enabled the public to distinguish between qualified and unqualified practitioners, and which created the General Medical Council, the functions of which were to maintain that register and to control medical education. This Act laid down the principle that the medical service of the country exists for the public interest and had called into existence the germ of a State medical service which he hoped in the future would be fully developed. From the medical profession itself, he said, there was a widespread demand for State interference, as was shown by the Bills now before Parliament, one of which aimed at the creation of a State medical examination. Few people realised to what an extent the medical profession was passing into the hands of the State. The Navy and Army Medical Services, the Colonial Service, the Public Health and Poor-law Services, the Prison and Asylum Services were all of comparatively recent origin. Sometimes some of these officers were also in private practice, but this was viewed with a growing distrust which would end in favour of "the whole-time man." These services in many ways compared favourably with other branches of the medical profession and their popularity was shown by the keen competition for certain of the posts. The medical man on entering private practice found himself, after spending many years in study, in a new world where he had to compete for patients; his prestige often depended upon his manners and social position and he was thrown upon the mercy of the public whose diseases he was called upon to treat. Whatever competition might do for trade it had nothing but a bad influence on professional work. In the matter of overwork the medical profession suffered more than any other profession as shown by the high mortality rate among medical men. There was just as good a case for legal interference in regard to overwork in the medical profession as in any other calling. Overwork and excessive night-work might lead to disaster just as it did in the case of the engine-driver or the signalman. Then there was a constant tendency on the part of the public to impose on the medical man and to seek from him gratuitous work. The organised workmen's societies led to the sweating of medical men. All hospital appointments, unless under State control, were practically unpaid, and certificates of various kinds were demanded by the public and by public bodies from the officers without payment. With regard to the question of hospital abuse some hospitals were trying to carry out a system of selection, but if a barrier of appearance was put up the poor clerk was excluded and the workman who was better off was admitted. In his view the suggestion to cut down hospital attendance displayed ignorance of human nature and a total incapacity to realise the grievances of the general public. During the 30 years in which the agitation against hospital abuse had been in progress the evil had been growing. Any solution of the problem to be satisfactory must take into consideration the case of the public as well as of the medical profession. The evils of the individualistic system of medical treatment resulted in most serious hardships to the middle classes, and an organised service of State medicine was, he considered, the only solution of the medical problem. But this ideal could only be brought about by public education. The important thing was to realise the fact that medical service was already in a state of transition, so that changes might now be effected along the line of least resistance. One of the first things that should be done was to secure the fixity of tenure of medical officers of health, who should have adequate assistance. Preventive medicine was taking a more and more important place. The public medical service, which would eventually have to be organised, should have connecting links between the ambulance bearer at one end and the consultant physician or surgeon at the other. It was also necessary that every man should be in some way connected with a hospital throughout his career so that the opportunities for scientific study might be constant. Hospitals would have to be placed on the rates and some form of insurance against sickness instituted. Members of the staff of a general hospital would then be paid just as the medical officers of the hospitals of the Metropolitan Asylums Board are paid at the present time. Another step would be the creation of a Ministry of Public Health. The cost of such a system should fall in part on the exchequer and in part on local taxation. A small tax in time of health would be more welcome, he was certain, to the public than the payment of a heavy doctor's bill at a time when it could be ill afforded.

A discussion followed in which Mr. L. HADEN GUEST, Mr. ADOLPHE SMITH, Mr. GRANVILLE BARKER, and others joined. It was suggested that the cost of such a system would be enormous, and that the condition of the housing of the population was the chief obstacle to the improvement of the public health of the country.

THE ADULTERATION OF WINES, SPIRITS, AND BEER.

AN interesting conference was held at the Institute of Hygiene, 34, Devonshire-street, London, W., on April 29th, which was largely attended by leading members of the medical profession, analytical chemists, lawyers, importers, distillers, brewers, merchants, and others. The subject chosen for discussion was, "The Adulteration of Wines, Spirits, and Beer, and its Effect on Health."

In opening the proceedings the Chairman, Sir WILLIAM BENNETT, K.C.V.O., said that opinions might differ as to the desirability of the use of alcoholic beverages, nevertheless, if these were used it was essential not only that they should be free from adulteration but that they should also be what they were represented to be. The conversion of the nation at large to total abstinence could, even now, only be regarded, he thought, as a remote contingency, and in the meantime the question of the purity of the various alcoholic beverages in common use amongst a large section of the people must be a matter of grave concern. There was a strong impression abroad that adulteration, substitution, and misrepresentation in connexion with the sale of wines, spirits, beer, and medicated beverages containing alcohol were rife, and if this impression was correct it could not be denied that such a condition of affairs was antagonistic to the welfare of the community and should no longer be tolerated. It also appeared that the means at present available for the prevention of the practices mentioned were virtually useless and in these circumstances the Institute of Hygiene—the primary object of which was the furthering of methods to insure the purity of all articles of consumption—thought it right to convene the present conference in order to obtain the views of those qualified to form a responsible judgment upon the matter, with the object, if after consideration it was thought desirable, of impressing upon the proper authorities the urgent necessity for providing adequate means for the prevention of those abuses which were commonly believed to exist.

Dr. F. J. SMITH proposed:—

> That the adulteration, substitution, and misrepresentation of wines, spirits, and beer affects the health and strength of the people, especially in connexion with its tendency to induce a craving for drink, and that the Local Government Board, licensing and other authorities be called upon to take such steps as are necessary to prohibit the sale of liquors which are not what they profess to be and the medical profession be appealed to to exert their influence to prevent their consumption.

He said that the medical profession saw so much of the evil effects of drink that they had the best claim to protest against any misrepresentation in connexion with the drink of the people. He referred to the manifesto that appeared in THE LANCET and said that though he had not signed it he could conscientiously have done so. He also condemned basis wines and so-called medicated wines, as they did much harm by the misplaced confidence which they received.

Dr. W. EWART, in seconding the motion, said that though inclined to limit the use of alcohol as far as possible, yet he gave his whole-hearted support to the motion and hoped it would lead to State action.

Mr. BRAMALL said that as a solicitor he had had much experience of cases dealing with misrepresentation and he fully approved of the motion and referred to the serious burden which now rested on those who had to prosecute.

The motion was carried.

Mr. CHARLES HAIG said that he had had 40 years' experience of whisky and he did not feel disposed to put much value o [illegible] ion of either medical men or analysts. He thought, however, that medicated wines did much injury, as they were made from the cheapest stuff and sold at enormous profit. He was also in favour of levying a tax on basis wines and wines made in this country and concluded by moving the following proposition :—

> That it is in the best interests of importers, producers, and purveyors of wines, spirits, and beer, and to their eventual profit, that every means should be taken to raise the standard of quality and discourage adulteration, substitution, and misrepresentation.

Mr. W. GILES seconded the motion and hoped that the public would be educated to appreciate good quality and to pay for it. He hoped British wines would be made under license.

Mr. W. PHEYSEY thought that the law was sufficient to meet adulteration if it were put in force, yet the production of basis wines required control and the sale of medicated wines was a great evil as they were sold as mixtures and tonics and often prescribed by medical men.

The motion was put to the meeting and carried unanimously.

Mr. S. ARCHIBALD VASEY, F.I.C., F.C.S., moved :—

> That it should be required by law that every bottle or vessel containing wines, spirits, or beer, intended for sale and consumption, should bear upon it a clear and accurate description of the contents and a statement of the source of origin.

He did not think adulteration was, on the whole, of a very serious kind—even basis wines could not be called unwholesome and there was no objection to them if they were honestly declared as British productions. He thought beer was never better than it was to-day but though substitution might not poison, it might cheat, and what was wanted was an honest label. He appealed to the Government authorities to deal decisively and without delay with the question of definitions.

Dr. T. DUTTON, in seconding the motion, said that the medical evidence went far to show that there was much merit in good sound wine and beer but substitution and adulteration were to be condemned as most injurious to health.

Mr. L. CAMPBELL JOHNSON thought the motion would be unfair to the British maker as it would not affect foreign producers.

Dr. J. C. THRESH proposed the following amendment :—

> That the Local Government Board should appoint a Court of Reference, including commercial and scientific experts, to define standards of wines, spirits, beer, cider, and similar fermented beverages.

This amendment was seconded by Mr. CAMPBELL JOHNSON and supported by Mr. CHAPMAN, F.I.C. It was put to the meeting and carried unanimously.

The motion was then put to the meeting but was not carried, the opinion being generally expressed that it would be very difficult to put into operation.

Mr. BRAMALL moved :—

> That two scientific gentlemen, members of this society, be appointed to join the deputation to the President of the Local Government Board to urge upon him to appoint a commission to fix a standard for Scotch and Irish whisky, in order to represent the importance of the matter in the interests of the public health.

This was seconded, put to the meeting, and carried.

Dr. THRESH proposed :—

> That the resolutions that have been passed at this Conference be submitted for the consideration of the Prime Minister, the Home Secretary, and the President of the Local Government Board.

This, too, after having been seconded and put to the meeting, was carried unanimously.

The Conference terminated by a cordial vote of thanks to Sir William Bennett for presiding.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on April 25th, Sir R. Douglas Powell, Bart., K.C.V.O., the President, being in the chair.

The following gentlemen having passed the requisite examination were admitted as Members of the College :—Julius Meyer Bernstein, M.B. Lond., L.R.C.P. Lond.; Wilfrid Edgecombe, M.D. Lond., L.R.C.P. Lond.; Daniel Cæsar O'Connell Finigan, M.D. Berlin, L.R.C.P. Lond.; Archibald Montague Henry Gray, M.D. Lond., L.R.C.P. Lond.; Thomas Lewis, M.B. Lond., L.R.C.P. Lond.; Newman Neild, M.B. Vict., L.R.C.P. Lond.; and Clifford Sidney White, M.D. Lond., L.R.C.P. Lond.

Licences to practise physic were granted to 114 gentlemen who had passed the necessary examinations.

The following Members, nominated by the Council, were elected as Fellows of the College :—Daniel Colquhoun, M.D. Lond.; James Barry Ball, M.D. Lond.; Arthur Shadwell, M.D. Oxon.; Arthur Thomas Wilkinson, M.D. Lond.; Edward Mansfield Brockbank, M.D. Vict.; William James Fenton, M.D. Cantab.; George Edward Rennie, M.D. Lond.; Edwin Bramwell, M.B. Edin.; Andrew Duncan, M.D. Lond.; Robert Jones, M.D. Lond.; Thomas McCrae, M.D. Toronto; and Herbert Stanley French, M.D. Oxon.

On the proposition of the PRESIDENT a letter of congratulation was sent from the College to Lord Lister on attaining the eightieth anniversary of his birthday, referring to the immense benefits which had been conferred on mankind through his researches.

The following communications were received :—1. From the secretary of the Royal College of Surgeons of England reporting proceedings of its Council on April 11th. 2. From the Geological Society of London, inviting the College to send a representative to take part in the centenary commemoration of the society's foundation on Sept. 26th to 28th next. The invitation was accepted and it was left to the President to nominate a representative.

A report was received from the Censors' board in the case of Arthur Rayner, L.R.C.P. On Dec. 12th, 1906, he was convicted at the Central Criminal Court of causing the death of a married woman by feloniously procuring abortion and was sentenced to three years' penal servitude. Having investigated the case the President and Censors resolved to report the case to the College, and in view of the serious character of his offence they unanimously recommended that the Licence of Arthur Rayner be revoked and altogether withdrawn and his name expunged from the list of Licentiates. The College adopted the recommendation.

Dr. Frederick Taylor was elected a representative of the College on the Senate of the University of London in place of Dr. W. H. Allchin whose term of office will expire on May 14th and who did not desire re-election.

The quarterly report, dated April 18th, of the College finance committee was received and adopted.

A report, dated March 18th, of the committee of management was received and adopted. The substance of the report was as follows :—

> 1. The committee recommend that for the future four examiners in anatomy and four examiners in physiology be appointed annually and that each College should appoint two examiners in each subject.
>
> 2. In reference to the present regulation requiring candidates to pass in chemistry and physics together, Regulation VIII. will now stand as follows: "A candidate must present himself for examination in Parts I. and II. together (unless he claims exemption from one of them under the conditions of paragraph XII.) until he has reached the required standard to pass in both, or in one of these parts, but he will not be allowed to pass in one part unless he obtains at the same time half the number of marks required to pass in the other part. A candidate may take Parts III. and IV. separately, or he may present himself for the whole examination at one time."
>
> 3. In reference to the commencement of the study of anatomy the committee recommended that Clause XIII. be altered as follows: "The study of anatomy and physiology will not be recognised until the candidate has passed in two of the first three parts of the First Examination—viz., chemistry, physics, and biology."

A report, dated April 15th, of the committee of management on the subject of the teaching of midwifery was received and adopted. The committee recommended that the regulations of the Examining Board in England should be altered so as to provide :—

> 1. That every student shall himself conduct 20 labours. 2. That before conducting such 20 labours he be required: (a) to have held the office of medical clinical clerk and of surgical dresser at a recognised hospital during six months each; and (b) to have attended a course of practical instruction in midwifery. 3. That the certificate of having conducted the required number of cases be signed by a member of the staff of a lying-in hospital or of the maternity charity of a general hospital, or by the dean of the medical school attached to the general hospital. 4. That every student be required to discharge the duties of clinical clerk in the gynæcological wards or out-patient department of a recognised hospital. 5. That every student be required to complete the curriculum of professional study before presenting himself for examination in midwifery and gynæcology.

A further report, dated April 15th, from the same committee was received and the following portions were adopted :—

> 1. A report from Dr. Theodore Dyke Acland on the examinations of the Egyptian Medical School, on the professional education at that school, and on the hospital accommodation at Cairo. The thanks of the College were accorded to Dr. Acland for his valuable services as assessor.
>
> 2. The Council of the Royal College of Surgeons having adopted the report of this committee, dated March 18th, with the exception of the clause relating to the distribution of the examinerships in anatomy

and physiology between the Royal Colleges, this clause was again taken into consideration by the committee. Under former conditions the Royal College of Surgeons appointed four examiners in anatomy, whilst the Royal College of Physicians appointed two of such examiners and three examiners in physiology were appointed by each College. The committee, on further consideration, felt that the reduction in the number of examiners would be more equitably brought about by each College giving up an examinership in each of the two subjects; the committee therefore proposed that three examiners in anatomy be appointed by the Royal College of Surgeons and one examiner by the Royal College of Physicians, and that each College should appoint two examiners in physiology.

After some formal matters had been transacted the PRESIDENT dissolved the Comitia.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 2nd, 1829.

ON THE PROPHYLACTIC POWERS OF BELLADONNA AGAINST SCARLET FEVER.

BY C. W. HUFELAND.

THE author has been led, both by his own experience and that of a great many other practitioners, to form such a favourable opinion with respect to the powers of this medicine, that he is convinced that in epidemics of scarlet fever it ought universally to be resorted to, as the best means of preventing the disease altogether, or mitigating its violence. The following are his general conclusions:—

1. The proper use of belladonna has, in most cases, prevented infection, even in those instances where, by the continual intercourse with patients labouring under scarlet fever, the predisposition towards it was greatly increased.

2. Numerous observations have shown, that by the general use of belladonna, epidemics of scarlet fever have actually been arrested.

3. In those few instances where the use of belladonna was insufficient to prevent infection, the disease has invariably been slight.

4. There are exceptions to the above three points, but their number is extremely small.

It seems that in some epidemics belladonna has no protective powers at all; the individual disposition, the method of using the remedy, and the quality of it will, of course, have considerable influence on the result of the experiment. Three grains of the extract, which must be recently prepared, are dissolved in three ounces of diluted alcohol; of this solution the individual takes, twice a-day, as many drops as he is years old; its use must be continued as long as contagion is possible. The dose, it appears, is so very small, that even if it should fail in its effect, it will, at all events, not be injurious.

In consequence of Hufeland's communication on the above subject, the Prussian government has issued an official decree, ordering the general use of belladonna, as a prophylactic in all instances when scarlet fever prevails as an epidemic.—*Liter. Ann. der ges. Heilk.*

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8663 births and 4910 deaths were registered during the week ending April 27th. The annual rate of mortality, which had been equal to 17·9, 16·9, and 16·8 per 1000 in the three preceding weeks, further declined to 16·0 in the week under notice. During the first four weeks of the current quarter the death-rate in these towns averaged 16·9 per 1000, the rate during the same period in London being only 16·5. The lowest rates in the 76 towns last week were 5·8 in Hornsey, 6·9 in King's Norton, 7·6 in Barrow-in-Furness, and 8·0 in York; the rates in the other towns ranged upwards to 23·0 in Wigan and in Swansea, 23·2 in Stockport, 25·6 in Middlesbrough, and 27·3 in Birkenhead. The 4910 deaths in the 76 towns showed a further decline of 239 from the numbers returned in recent weeks, and included 532 which were referred to the principal epidemic diseases, against 569, 544, and 506 in the three previous weeks; of these, 226 resulted from measles, 167 from whooping-cough, 47 from diphtheria, 36 from diarrhœa, 34 from scarlet fever, and 22 from "fever" (principally enteric), but not one from small-pox. No death from any of these epidemic diseases was registered last week in Southampton, Swansea, Huddersfield, Rochdale, York, or in nine other smaller towns; the annual rates from these diseases, however, ranged upwards in the other towns to 4·4 in Birkenhead, 4·5 in Sheffield, 4·6 in Bolton, and 5·3 in Portsmouth. The fatal cases of measles in the 76 towns, which had been 251, 228, and 216 in the three previous weeks, rose again to 226 last week; the highest annual rates therefrom were 3·0 in West Bromwich, 3·1 in Birkenhead, 3·2 in Nottingham, and 4·0 in Sheffield and in Portsmouth. Whooping-cough also showed increased fatality and was proportionally most fatal in Brighton, Tottenham, Stockton, and Salford. The deaths referred to diphtheria, diarrhœa, and scarlet fever were also more numerous than in the previous week. Scarlet fever was most fatal in Wigan, and diarrhœa in Rhondda and Tynemouth. Of the 22 deaths referred to "fever," three occurred in Wigan, equal to an annual rate of 1·8 per 1000. One case of small-pox was under treatment in the Metropolitan Asylums Hospitals at the end of last week, being the first case admitted to these hospitals since the end of June last. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2637 and 2628 in the two previous weeks, rose again to 2665 at the end of the week under notice; 360 new cases were admitted during the week, against 298 and 361 in the two preceding weeks. The deaths referred to pneumonia and other diseases of the respiratory organs in London, which had been 412, 355, and 326 in the three previous weeks, further declined last week to 295, and were ten below the corrected average number in the corresponding week of the five years 1902–06. The causes of 49, or 1·0 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Newcastle-on-Tyne, Salford, and in 50 other of the 76 towns; the proportion of uncertified deaths, however, again showed considerable excess in Liverpool, Birmingham, St. Helens, Warrington, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 20·2 and 20·0 per 1000 in the two preceding weeks, rose again to 20·6 in the week ending April 27th, and exceeded by 4·6 the mean rate during the same week in the 76 large English towns. The rates in the eight Scotch towns ranged from 17·0 and 17·6 in Aberdeen and Dundee to 24·2 in Glasgow and 22·5 in Leith and Perth. The 714 deaths in the eight towns were 19 above the number in the previous week, and included 121 which were referred to the principal epidemic diseases, against numbers increasing steadily from 100 to 133 in the six preceding weeks. These 121 deaths were equal to an annual rate of 3·5 per 1000, which exceeded by 1·8 the rate from the principal epidemic diseases in the 76 English towns; they included 52 from whooping-cough, 39 from "fever," 12 from diarrhœa, 11 from measles, six from diphtheria, and one from scarlet fever, but not one from small-pox. The 52 fatal cases of whooping-cough were within two of the number in the previous week, and included 43 in Glasgow, and two each in Edinburgh, Aberdeen, Paisley, and Greenock. The 39 deaths referred to "fever" showed a further decline of three from the high numbers in the two previous week, but included 27 in Glasgow, nine in Edinburgh, two in Leith, and one in Dundee; of these deaths from "fever," 26 were certified as cerebro-spinal meningitis in Glasgow, eight in Edinburgh, two in Leith, and one in Dundee. The 11 deaths from measles showed a decline of six from the number in the previous week, and included five in Glasgow and four in Edinburgh. Of the 12 deaths attributed to diarrhœa six occurred in Glasgow and two in Perth; and of the six fatal cases of diphtheria three were returned in Glasgow and two in Greenock. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 118 and 103 in the two preceding weeks, rose again to 109 in the week under notice, but were 26 below the number in the corresponding week of last year. The causes of 22, or 3·1 per cent., of the deaths registered in the eight towns during the week were not certified or not stated; in the 76 English towns the proportion of uncertified deaths in the week under notice did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 26·6 and 27·4 per 1000 in the two preceding weeks, further rose to 33·5 in the week ending April 27th. During the first four weeks of the current quarter the death-rate in the city averaged 28·9 per 1000, the rates during the same period did not exceed 16·5 in London and 17·6 in Edinburgh. The 251 deaths of Dublin residents during the week under notice showed a further increase of 48 upon the high numbers in recent weeks, and included 29 which were referred to the principal epidemic diseases, against 19 and 18 in the two preceding weeks; of these, 15 resulted from whooping-cough, ten from measles, two from "fever," and one each from diphtheria and diarrhœa, but not one either from scarlet fever or small-pox. These 29 deaths were equal to an annual rate of 3·9 per 1000, the rate during the same week from the principal epidemic diseases being 1·7 in London and 2·4 in Edinburgh. The fatal cases of whooping-cough showed a considerable further increase upon recent weekly numbers; and those of measles corresponded with the number in the previous week. Two fatal cases of cerebro-spinal fever were also registered. The 251 deaths from all causes included 53 of children under one year of age and 71 of persons aged upwards of 60 years; each of these numbers showed a marked increase. Seven inquest cases and seven deaths from violence were registered; and 89, or 35·5 per cent., of the deaths occurred in public institutions. The causes of six, or 2·4 per cent., of the deaths in Dublin were not certified; the percentage of uncertified deaths during the week did not exceed 1·0 in London and 1·6 in Edinburgh. The 170 deaths registered in Belfast during the week under notice included 27 referred to cerebro-spinal fever or cerebro-spinal meningitis, corresponding with the number in the previous week.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Deputy Inspector-General: J. Crowley to Haslar Hospital. Fleet Surgeons: E. R. D. Fasken to the *Cressy*, and W. E. Home to the *Excellent*.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Richard Edmund Biddulph has been placed on the retired list, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets (dated April 28th, 1907).

ROYAL ARMY MEDICAL CORPS.

Colonel Matthew D. O'Connell is placed on retired pay (dated April 5th, 1907).

Colonel A. T. Sloggett, C.M.G., has been appointed to examine Militia and Yeomanry candidates for commissions in the Regular Army in London. Major A. E. C. Keble has been noted for appointment to Sierra Leone as Sanitary Officer.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant-Colonel Charles W. Thorp having reached the prescribed limit of age ceases to belong to the Army Medical Reserve of Officers (dated April 9th, 1907).

IMPERIAL YEOMANRY.

Northumberland (Hussars): Hamilton Drummond to be Surgeon-Lieutenant (extra), under the conditions of paragraph 28, Imperial Yeomanry Regulations, 1906 (dated March 18th, 1907).

VOLUNTEER CORPS.

Royal Garrison Artillery: 4th West Riding of Yorkshire: Surgeon-Lieutenant A. M. Connell to be Surgeon-Captain (dated March 19th, 1907). 1st Sussex: Thomas Sanders Worboys to be Surgeon-Lieutenant (dated March 1st, 1907).

Rifle: 2nd Volunteer Battalion the Prince of Wales's Volunteers (South Lancashire Regiment): Douglas Catterall Leyland Orton to be Surgeon-Lieutenant (dated March 15th, 1907).

ARMY MEDICAL SERVICE.

An examination of candidates for not less than 30 commissions in the Royal Army Medical Corps will be held on July 25th next and following days. Application to compete should be made to the Secretary, War Office, London, S.W.

CLASS FOR INSTRUCTION IN MILITARY MEDICAL ORGANISATION.

In consequence of the success which in the West of London attended the movement for initiating the formation of an organised Army Medical Civilian Reserve, it is proposed to hold another class this summer. The instruction will be given by specially experienced officers of the Royal Army Medical Corps at a convenient place for medical men residing in the metropolis. The importance of this class is increased by the certainty that trained civilian medical coöperation will have to form a part of the organisation of the new "territorial force." Gentlemen desirous of joining this class are requested to send their names to the acting honorary secretary, Mr. Herbert Chambers, 101, Goldhawk-road, London, W.

Correspondence.

"Audi alteram partem."

CEREBRO-SPINAL MENINGITIS.

To the Editors of THE LANCET.

SIRS,—Owing to the increase of this disease and to the alarming percentage of mortality in such cases, I venture to trouble you again with my opinion as to a possibly favourable treatment. Death is chiefly certified as finally due to coma; and I am sure this is a coma due to mechanical pressure, not to toxæmia. I therefore suggested in your columns last autumn the desirability of relieving this by surgical means. I then described a suitable operation for the purpose—viz., cervico-spinal laminectomy with capillary drainage in the serous stage, or tubal in the purulent condition that usually precedes a fatal issue. The operation on the fourth or fifth left cervical lamina is safe and quite easy, as I have now tried it on the cadaver although unable to try it on the living subject. The left lamina should be turned up as a flap, leaving its dorsal periosteum adherent; and if the treatment be successful, may be returned to its original position so as to leave no patent opening. At the critical point of the disease free drainage into copious antiseptic absorbent dressings may tide over the crisis and pave the way to recovery. The free use of leeches clearly saved two lives out of the nine cases I saw last autumn, and led me to feel that more thorough depletion or relief of tension might save many more. The suggestion has not been taken up, and I should not have troubled you by its repetition had the disease with its attendant serious mortality not increased to such an alarming extent. But till the "sero-pentists" have provided us with a reliable vaccine serum I think the surgeons should not neglect the obvious and yet dangerless method of relieving tension at a critical period of the disease.

I am, Sirs, yours faithfully,

Newquay, Cornwall, April 28th, 1907. ARTHUR W. HARE.

HEART FAILURE DUE TO AIR EMBOLISM.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of April 27th, p. 1182, is a reference to a fatal case of air embolism. A fatal result usually implies a large and rapid entry of air. I have repeatedly noticed the entry of air into a vein, especially during operations on the neck, without the slightest ill effect on the patient. I have often seen air bubbles injected with the saline solution during intravenous infusion, no obvious harm resulting. A hissing noise, similar to that caused by the suction of air into a vein, may be produced by the passage of air between separated layers of muscle or fascia, when the space between these layers is opened and closed by respiratory movements. Therefore in a given case the mere occurrence of a hissing noise, the heart's action remaining unimpaired, is not proof positive that air is entering a vein. The rapid entrance into a vein of air, in sufficient quantity to arrest the action of the heart, produces a surgical emergency in which prompt treatment can alone give the patient a chance of recovery.

Delore and Duteil,[1] in discussing the cause of death, hold that it consists not simply in obstruction of the pulmonary capillaries, but in an association of pulmonary embolism with weakening of the heart's action due to distension of the cavities on the right side. They suggest as treatment aspiratory puncture of the right ventricle. This minor operation is regarded by Delore and Duteil as quite free from risk and likely, if practised without delay, to be as beneficial on the human subject as it has proved to be on animals.

In carrying out this treatment I would add the following suggestions. After closure by pressure of the wound in the vein incise the skin prior to passing the needle, which can be manipulated more accurately when the resistance of the skin has been removed. Where available a fine trocar and cannula should be employed in preference to a needle, the trocar being removed as soon as the heart cavity is reached in order to prevent injury by the point of the trocar. If an aspirator is not at hand a reversed enema syringe may be fitted to the cannula, but in the absence of suitable apparatus the surgeon will probably be obliged to fall back on suction made with his lips in order to evacuate the blood-stained froth, a short length of rubber tubing being attached for this purpose to the cannula. Artificial respiration will be necessary and may assist in furthering the flow of froth and blood. I am, Sirs, yours faithfully,

Plymouth, April 28th, 1907. C. HAMILTON WHITEFORD.

THE USE OF ALCOHOLIC BEVERAGES.

To the Editors of THE LANCET.

SIRS,—Whilst this subject is being discussed in your columns I should like to point out a class of case in which the use of brandy or whisky is, in my opinion, of undoubted therapeutic value—viz., cases of retention of urine, either from an enlarged prostate or stricture of the urethra, in which patients have to undergo life-long catheterisation. It is my experience that men who make use of brandy or whisky as a drink escape cystitis from decomposition of the urine more frequently than do total abstainers, and I frequently administer half an ounce of brandy or whisky immediately after the operation. It revives the patient and makes him feel comfortable and happy. If alcohol is excreted by the kidneys and appears as such in the urine, and if it is an antiseptic its therapeutic value must be apparent. I am, Sirs, yours faithfully,

Exeter, April 30th, 1907. JOSEPH A. W. PEREIRA.

PHARYNGO-KERATOSIS TREATED BY APPLICATIONS OF SALICYLIC ACID IN SULPHO-RICINATE OF SODA.

To the Editors of THE LANCET.

SIRS,—In the report of a case illustrating the above, which I brought before the Laryngological Society at its meeting on April 5th, a very important fact, and, indeed, the one which gave the main value to the case, was omitted. This was to the effect that the condition—best known as pharyngo-mycosis—was well marked on both tonsils, but that after the patient had made a daily application of a 10 per cent. solution of salicylic acid in sulpho-ricinate of soda to her right tonsil only, a slow but steady diminution in the size and in the consistency of the spots on it was observed after a few weeks. The other tonsil remained as before until the same application was made to it also. This rigid experimental test showed incontrovertibly that the improvement was due to the application and not to any coincidental spontaneous disappearance such as we know to take place from time to time in this disease. It is generally agreed that the condition is really one of no importance, and if a patient can be persuaded to disregard it so much the better; for those, however, who are impatient of the condition, it is gratifying that there should be a method of treatment which has an unmistakeable action on the keratotic condition and which can be placed in their own hands. The action is, of course, analogous to that of salicylic acid upon warts, corns, and similar conditions, and the sulpho-ricinate of soda seems to be the vehicle with which it can be incorporated so as to be as unirritating as possible. In view of the policy I have above described of dissuading patients from submitting to treatment for this condition the opportunities for observing the effect of such treatment are obviously very few. Thanking you for allowing me space for this communication,

I am, Sirs, yours faithfully,

May 1st, 1907. DUNDAS GRANT.

MEDICAL OFFICERS OF HEALTH AND RURAL DISTRICT COUNCILS.

To the Editors of THE LANCET.

SIRS,—In my annual reports to the Oulton Broad urban district council and the Mutford and Lothingland rural district council for 1905, when dwelling upon the Oulton Isolation Joint Hospital, the property of the above-mentioned authorities, I made the following comments:—

> The bathing accommodation is lamentably deficient, there is only one bath in the hospital, this is an ordinary wheel bath and this is not in a very good state, so that patients suffering from scarlet fever, diphtheria, and enteric fever all have to use the same bath. There is another bath at the institution, one in the caretaker's house, but that should be for the use of the staff only. Before a patient can be discharged he or she must go over to the house and take his or her final bath in this one. This, gentlemen, is far from what it ought to be; it is, to say the least, not nice for the staff. What is really required is a discharge room with a proper bath, etc., for each ward.

The hospital consists of four wards built upon the pavilion system, each ward being bedded for four patients, though more are admitted. One block, consisting of two wards, is mostly used for cases of typhoid fever and diphtheria; the other two wards are reserved for cases of scarlet fever.

In my annual report for 1906 which I am now forwarding you (on page 33) you will notice that that condition of affairs *re* bathing still obtained[1] and that I again drew the committee's attention to this lamentable condition of affairs. This report has caused several personal attacks upon myself at meetings of the committee. I was told that the report should not have been presented to the council and that no representations had ever been made to the committee that another bath had been required and that I ought to have apologised for having written such a report. At a meeting of the hospital committee held on the 5th inst. the member whose speech of the 25th inst. *re* cost of patients was reported in the *Eastern Daily Press* of the 26th inst., insinuated in a most aggravating form that my transaction bearing on a matter of the provision of shrubs to the hospital when the grounds were being laid out some two years ago might not have been of a honest and straightforward nature, and the direct impression conveyed to my mind was that I might have been a party to fraud. These hostile attacks culminated in the statements made as per reports of the two newspapers, which I beg to submit for your perusal.

It must come as a revelation to medical superintendents of isolation hospitals that it is a part of their duty on receiving a request for the removal of a patient to hospital to visit and examine the case asked to be removed for the purpose of verifying the diagnosis of the medical brother who has notified the case. What would the Local Government Board say on this matter? What would the medical profession think and say? Is it any wonder that the present Government contemplates taking away the administration of the Public Health Acts from the rural district councils? Is it possible to work in harmony with such bodies and at the same time do one's duty for the welfare of the districts? You will notice that what seems to me to be a direct attack upon myself is made by the member Mr. M. more particularly affecting the administration of the hospital. The figures quoted, as supplied to him by the clerk, I have not as yet had an opportunity of proving. He is wrong to start with, with regard to the number of patients admitted during the years of 1901 and 1902, he giving a much higher number than that actually admitted to hospital, as proved by the register of cases. My connexion with the hospital did not start until 1904. The whole of the figures are jumbled up, including establishment charges, salaries, and everything else. I am expected as medical superintendent to pay the staff, keep a record of all petty cash transactions; so well, so good. At the quarterly meetings of the committee I have to initial all bills presented for payment, including grocers, butchers, milk, drapery, chimney-sweeps, and every other tradesman, and, as you see from the report, am expected to work out the daily cost of maintenance per head, both for patients and staff. Does the medical profession consider these to be the duties of a medical superintendent? There is a clerk—a qualified solicitor—whose duty is it to get out these statements, his or mine? There is a matron. Is it the medical superintendent's duty to examine and check her provision accounts, drapery account, and every other petty account? I shall be glad of your opinion on these points and also any opinion which a medical superintendent may express bearing upon these questions. Would the Local Government Board sanction an inquiry as to my administration of the hospital? Thanking you in anticipation, I am, Sirs, yours faithfully,

---

[1] Revue de Chirurgie, No. 3, 1905.

[1] Since the report was printed another bath for patients has been supplied, but discharged patients still take their final bath in the bath supplied for the staff.

SAMUEL J. J. KIRBY.

Oulton Broad, Lowestoft, April 29th, 1907.

A DISCLAIMER.

To the Editors of THE LANCET.

SIRS,—I beg leave to disclaim any association with the medical part of the article which appears in the current number of *Great Thoughts*. In my capacity as President of the Ethological Society I was recently requested to grant an interview on the subject of ethology, which I did, but cautioned the interviewer that I could not allow any medical questions and that I should have to see a proof of the article. This was forwarded to me in due course and returned with my corrections.

To my surprise, on seeing the paper I found considerable additional matter of which I had no knowledge and which, contrary to my express instructions, had reference to my medical work. The offence was made worse by putting the words, which were collaborated from my books, as if spoken by me. I wrote at once to the editor, who replied expressing his regret that the additional matter "was inserted against my wishes" and explained that on "finding the interview was somewhat shorter than those we usually have I inserted the paragraph myself in order to fill up the page after you had seen the proof, as I thought it made interesting copy." Both editor and sub-editor tendered their apologies.

I am, Sirs, yours faithfully,

May 1st, 1907. BERNARD HOLLANDER.

MEDICAL EDUCATION AND THE UNIVERSITY QUESTION IN IRELAND.

To the Editors of THE LANCET.

SIRS,—A recent annotation in THE LANCET entitled "The Irish University Question" emboldens me to write you a rather long letter. The question is one that concerns the education of Irish medical students acutely, but it is too often dismissed with a shrug of the shoulders because of its intricacy, which, I think, is more apparent than real. I venture on a statement of the situation in the hope that it will enable your readers to see what are the real difficulties, feeling sure that in this way the medical student of Ireland will secure their sympathies regardless of political or religious points. When a boil on the neck of a Unionist presents other characteristics than those of a boil on the neck of a Nationalist, when the dislocated shoulder of a Roman Catholic requires different treatment from that required by the dislocated shoulder of a Protestant, when Dublin influenza loses its similarity to Belfast influenza, the medical student will be interested, and interested fundamentally, in racial, religious, and geographical bickerings. At present he wants peace and opportunities for instruction.

Ireland possesses at the present moment the University of Dublin (Trinity College), the Royal University of Ireland (with an office in Dublin and colleges at Belfast, Cork, and Galway), and the Catholic University of Ireland, with its six constituent colleges of Maynooth, University (actually confused in English minds with Trinity College), Blackrock, Carlow, and Clonliffe. The result of this apparent wealth of educational opportunities is that medical education in Ireland is on the wane; we not only do not progress as England and Scotland do but we have begun to go backwards. Trinity College, Dublin, founded more than 300 years ago, has a distinguished past and a successful present. The reasons for tampering with it must be very strong before they can weigh against these facts. The Royal University of Ireland and the Catholic University of Ireland have at any rate no sentimental claims upon tender handling, and if any re-arrangement of university education promising medical and scientific students better chances should be persevered in, even though it should interfere with the present position of these institutions, I do not think their own professors would take a different view.

I make no claim to originality for much of what follows; I have adopted the views of well-informed men. The Royal University of Ireland was established by Lord Beaconsfield in 1879. At the old Queen's University which it superseded a boy *must* have been at the (legally speaking) undenominational colleges at Belfast, Cork, and Galway. But the Roman Catholics objecting to this mixed education, and supported in their objection by the unfortunate fact that the first professors in the three Royal Colleges were Protestants, boycotted the three Royal Colleges and founded in 1854 a Catholic University. Parliament, however, refused a charter to this university and until 1879 the State position was, as far as the Roman Catholic community was concerned, that they could use the undenominational colleges at Belfast, Cork, and Galway, or Trinity College, Dublin, where, as at the three Royal Colleges, the teaching was all in the hands of Protestants. Then came the Royal University of Ireland, founded, it would seem, with the rather Machiavellian intention of indirectly endowing Roman Catholic education. The result of this has been that the Roman Catholic students are examined for their medical degrees to too great an extent by their own professors while the students from Belfast, Galway, and Cork only receive occasional benefit in this way. This accounts, say the professors of Belfast, for the proud position in the honours list of the Royal University of Ireland enjoyed by University College, Dublin. University College, Dublin, needless to say, denies the impeachment, and attributes the admittedly high proportion of academic successes obtained at the University by their students to the application of the pupils and the zeal of the masters.

How does this position affect medical education in Ireland? There is perpetual friction kept up between North Ireland and South Ireland, all idea of the undenominational university is lost, the best students do not go in for the best examinations, the best men for educational posts do not necessarily get them, recrimination occurs between the leaders of thought who ought to be working hand in hand for the best education of the fine material supplied to them by their country. As far as medical education is concerned there is, it seems to me, but one remedy for such a state of affairs—the creation of two brand new universities for Ireland. It is the fact, a fact that will be considered reasonable by one school of thought and regrettable by another, that the Roman Catholics do not approve of mixed education; they will not, if they can avoid it, allow their students to be educated with Protestants, however clearly the rules of the particular institution show that unsectarian education is intended. Now, three-quarters of the population of Ireland are Roman Catholics, a fact which gives them an overpowering right to ask that their views should be met. But if a Roman Catholic university is started in Dublin an unsectarian university should be erected at Belfast, where the students of Belfast, Galway, and Cork could be examined for their medical degrees without the possibility of favouritism and in fair circumstances. Of course, it is dead against modern ideas to found universities with religious restrictions—the great universities of the world have abolished them—but the circumstances in Ireland are peculiar and it seems to me that all Irish medical men should press for the foundation of two new universities and *for peace*, without which the famous Irish medical men will grow less in number and influence. Trinity College, Dublin (Dublin University), would in this way be forced into no unsuitable alliance. The Royal University of Ireland would enjoy fair play and a Roman Catholic university would minister to the educational needs of a country that is largely Roman Catholic in creed.

I am, Sirs, yours faithfully,

CHARLES O'MALLEY.

⁂ Our correspondent's statement, contrary to his design, shows that the whole question bristles with difficulties. Many of them are not touched upon by the writer and most of them cannot be discussed in THE LANCET which is a medical paper. We publish this letter because he has approached the subject from the point of view of the medical teacher, but there is no solid support of his views, so far as we know, among his medical colleagues in Ireland.—ED. L.

THE BUDGET.

To the Editors of THE LANCET.

SIRS,—The cruel and iniquitous income-tax, which is apparently to be maintained at the war level of 1*s*., weighs with special injustice on the medical man. His earnings are not income, properly speaking, but realisation of the capital of his health, strength, and life, and the remission of 3*d*. up to £2000 a year from all sources is totally inadequate as a recognition of this fact. Any method by which its incidence may be minimised is worthy of the attention of the profession, and I may perhaps be permitted to cite my own example.

In the first place, instead of making an allowance to my children, I divided my savings among them as far as was consistent with prudence. It is a long time before the interest on the subdivided capital reaches an amount which renders it liable to the tax, and the time when the total income from earnings and dividends amounts to £2000 is retarded. The amount of the death duty also is reduced. An attendant advantage is that boys early learn the value of money and become accustomed to financial responsibility, they are less likely to be spendthrifts than if they come into a considerable amount all at once. A further precaution is to insure largely, arranging that all premiums are to be paid at or before the age of 60, so that they do not become a burden when the earning power is reduced. Happily, in order to encourage thrift previous Governments have allowed life insurance premiums to be deducted from income liable to taxation. It is not amiss to make a part of the insurance payable at a certain age as a provision for evil days. Bonuses taken in cash instead of being added to the amount insured may perhaps be very welcome in some cases in old age. As a profession we are lamentably improvident, and if we are stung by injustice into better ways it may be good for us. I am, Sirs, yours faithfully,

April 25th, 1907. M.D.

THE RECENT CASE OF PHOSPHORUS POISONING.

To the Editors of THE LANCET.

SIRS,—According to White Paper Cd. 3373, the man Thomas Davis, engaged at Messrs. Morlands' match factory, whose death occasioned the inquiry referred to, was engaged in removing splints which had fallen on to the dipping table by means of a species of toasting fork, not engaged in pouring phosphorus composition on to the revolving table. The remover of the splints should not be exposed to phosphorus fumes to anything the same extent as the "dipper," who pours on the paste and attends to the removal of the frames. If the man had been employed as a frame-dipper or with the phosphorus paste it would have, I think, constituted a breach of the special rules. Apparently the direct cause of the poisoning was the conveyance of phosphorus to the mouth, *but* the fact that such a man was employed in what must always be a dangerous process, unless entirely automatic, raised the question alluded to in the first paragraph of your leader.

I am, Sirs, yours faithfully,

April 27th, 1907. M.R.C.S.

THE ACTIONS OF FORMIC ACID AND THE FORMATES.

To the Editors of THE LANCET.

SIRS,—It is interesting in this connexion to note that many folk-lore stories relate that stinging or biting by ants will revive the dead. So we have the following story from Tasmania: "Two women were impaled by a sting ray and died. Two black fellows, the bringers of fire, who are now stars, took the bodies, laid them between great fires, and having collected many ants, placed them on their breasts. Severely, intensely were they bitten. The women revived, they lived once more, and are now the companions of the black fellows in the sky."[1]

I am, Sirs, yours faithfully,

April 30th, 1907. FORMICA.

THE MARSEILLES MUNICIPAL ABATTOIR.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

IN describing the great Paris municipal slaughter-house of La Villette I related how the butchers constituted a privileged corporation. Their influence it was that defeated the excellent reforms introduced at the commencement of the last century. In many provincial towns the large slaughter hall was substituted for the private small shambles. But the corporation of the Paris butchers prevented the adoption of this principle when in 1810 the decree ordering the town of Paris to build public slaughter-houses was published. The worst of this is that other towns thought that they could not do better than follow the Parisian example. In Germany and in Switzerland, on the contrary, the example given in the French provinces was followed, while in France the provinces themselves abandoned what they had done so as to imitate Paris. It has taken not far short of a century to convince the French of their error in this respect. Perhaps one of the most remarkable illustrations of this fact is the new municipal slaughter-house of Marseilles. As the buildings were inaugurated *in January, 1895, they* may be considered as, comparatively speaking, new. What is more, the people of Marseilles are very proud of their public abattoir, and in a sense it does credit to the town. The buildings are well situated, they are well kept, they cost a great deal of money, and they may be described as almost palatial. Unfortunately, it remains the fact that a more modest style of architecture, less expenditure of money but a more scientific plan would have given better results. The fault, however, rests with Paris. The architect himself in his report on the subject states that he visited some neighbouring public slaughter-houses, that he only travelled 860 kilometres, and he rests his principal claim for the justification of his plan on the fact that he thoroughly examined the cattle-market and slaughter-house of La Villette.

The members of the Marseilles municipal council probably knew nothing whatsoever about the building of slaughter-houses, therefore they doubtless thought that if the architect's plan was based on what had been done in Paris they could not go far wrong in approving the scheme This was, of course, the greatest mistake that could have been committed, for France was taking the lead in Europe in this matter till the fatal example given in Paris threw the whole nation back and now it is Germany which is first on the list. If the architect employed by the town of Marseilles had not visited the neighbouring abattoirs and had avoided Paris altogether but had gone to Germany instead he would have learnt something and could have put Marseilles at the head of the movement, *instead of building in 1894* a public abattoir which is not so appropriately planned as the public slaughter-house *in the* town of Rochefort built in 1790 or as those built by the towns of Blois and Grenoble about a century ago. But what is even more remarkable is the fact that Marseilles used to possess in olden times a public slaughter-house *which was* planned much more in accordance with modern ideas than its present and new abattoir. There is a standard work on the subject entitled "Études relatives à l'Art des Constructions," written by L. Bruyère, formerly director of public works of Paris, and published in 1823. In this book Bruyère describes several slaughter-houses and he says: "Marseilles possesses a large abattoir situated outside the town and near to the lazaret. Its quadrangular plan is divided into three equal parts by a double row of pillars. The space in the centre is allotted to the carriages and the animals and people that pass to and fro. The two lateral *portions serve one* for the slaughtering and the other for the storage of the carcasses." As M. J. de Loverdo in *Les Abattoirs Publics* remarks: "This disposition appears altogether remarkable, for it seems to us analogous to what has been realised by the last improvements effected by German architecture. These three sections of the old Marseilles abattoir recall the general plan of the Breslau, the Offenbach, and other German slaughter-houses. The central part can be compared with the central hall of intercommunication reserved for carts and workers, and which connects the slaughter-hall that is on one side and the modern cold storage for the carcasses which is on the other side."

To build the new slaughter-house at Marseilles, which, at least theoretically, is not so well designed as the old slaughter-house, the cost in space and money was greater than if the old plan had been utilised but on a larger scale. The modern abattoir is built in the Cabucelle quarter, well away from the town and on a height which dominates the Bay of Madrague beyond the Joliette docks. Close to the sea shore, conveniently near to the landing quays, there is a large cattle or sheep market. This is an abominable place. All the partitions are made of wood and it does not seem to have occurred to anyone that the risk resulting from the employment of wood might be reduced if it was frequently whitewashed. This market is used for the animals, mostly sheep brought over from Algeria. The absurd thing about it is that these animals are not killed on the spot. Many of them are sent by rail into the interior and put out to grass. On the other hand, on the summit of the hill overlooking this market and where the new slaughter-house has been built, there is a small but quite modern cattle and sheep market. The animals that are brought here, however, are killed almost immediately, so that it would not have mattered so much if they occasionally rubbed against some contaminated wooden partitions or stood on muddy, porous ground saturated with manure. The animals would be killed probably before any disease that they might contract had time to develop. In any case, it is obvious that the danger is much greater if cattle are to travel considerable distances. All markets should be properly constructed and properly drained, and the place where the animals stand should be water-tight and no contamination of the subsoil shall be possible. But if any exception to such rules could be tolerated it would be in regard to animals that are to be slaughtered at once. At Marseilles, on the contrary, the sanitary market is reserved for the animals that are to be killed and the insanitary market for the animals that are not to be killed. At most the animals that are bought at the cattle market adjacent to the slaughter-house may be kept for a night or two in stables prepared for that purpose and situated on the premises. From the sanitary point of view these stables are inferior to the market. They are paved with uncemented cobbles and as these stones give way and are displaced pools of liquid manure form in the hollows. The mangers are of wood and the stables are not as frequently or as thoroughly cleaned out as is desirable. Also, it may be noted that these stables are at some distance from the slaughter pavilions. These are built on much the same plan as at La Villette, but in Paris the stabling is nearer at hand and therefore more convenient.

---

[1] The Childhood of Fiction: a Study of Folk Tales and Primitive Thought, by J. A. Macculloch, London, John Murray, 1905.

There are three large pavilions for the slaughtering of horned cattle and sheep. As at Paris, each pavilion has a vast central space or court and on each side there are numerous partitions where the butchers may work in private. Some critics have expressed the opinion that these pavilions are not high enough. In any case, there seemed to me to be ample ventilation and light. On the occasion of my visit the greater part of the day's slaughtering was terminated, but there were still some animals remaining to be killed. Going among these I did not notice any evil odours. The viscera were promptly removed. The paunches, intestines, in fact whatever could not be swept out of sight into the drain, were promptly conveyed to carts and these carts are taken away daily by a dealer in manure. The floors of the slaughter departments are well cemented and drained and the fittings are for the most part of iron. All this I was assured was thoroughly scoured out twice a day and here and there wherever an accumulation of dirt occurs the place is washed at once. Thus partial cleaning is going on all day long. Outside there is a magnificent broad avenue planted with oriental plane-trees. Their luxurious foliage and gigantic leaves afford grateful shade during the hot days of summer.

On the opposite side of this majestic row of trees and spacious avenue there are smaller buildings. In two of these a number of persons, for the most part women, work at preparing tripe. This is always dirty, unpleasant work, and it is very necessary that it should be done under the strict surveillance of responsible municipal officers. Therefore the tripe dealers must come to the slaughter-house and are placed in lofty, well-lighted, and ventilated buildings. Here there is an unlimited supply of hot and cold water but the monthly charge is 32 francs (25*s*. 7*d*.) per tap and 6*s*. 10*d*. per seat. The place is divided into compartments, each large enough for 12 persons to work together under one employer. In another building the same sort of provision is made for preparing sausage skins, &c., and this likewise is a bye-product which cannot be produced without creating considerable nuisance. It is therefore well that these trades should be carried on in isolated specially constructed buildings well away from dwelling-houses. In all these respects the care taken and provision made at Marseilles are well worthy of commendation.

The slaughter-house for hogs is much more in accordance with modern principles than is that for horned cattle. It is a slaughter hall. Large flag-stones, measuring some 6 by 3 feet, are employed as tables and are easy to keep clean and are non-absorbent. The floors are cemented as also is the lower portion of the walls. There are iron cauldrons for scalding the pigs and there is no absorbent material anywhere. Perhaps, however, what is most to be praised at the Marseilles abattoir are the very admirable laboratory and physiological museum which face the main entrances. There extensive microscopic researches have been made and the veterinary surgeons have all the necessary space and utensils to pursue their scientific studies. The inspecting staff consists of a chief veterinary surgeon, two assistants, and 16 inspectors. The number of animals killed during the year 1905 was: bulls, bullocks, and cows, 33,150; calves, 29,802; sheep, 197,198; lambs, 40,311; and hogs, 39,923. Then there were also 7481 horses and mules and 405 donkeys slaughtered. The charges—that is, the payments made to the municipality for the use of the abattoir by the butcher—are: 3 francs 50 centimes per head for killing horned cattle, 35 centimes per head for sheep, 30 centimes per head for lambs, 2 francs 50 centimes per head for hogs (this includes the scalding for removing the bristles, &c.), and 1 franc 50 centimes per head for calves. Thus, taking the largest item, the 33,150 horned cattle at 3 francs 50 centimes each, this makes 116,356 francs (or £4654) income for the municipality. No fear is entertained that the debt contracted to build the slaughter-house will be paid off in course of time and then the public abattoir will provide a fruitful source of public revenue. From the public health point of view it would have been desirable that this institution should have been constructed more in accordance with modern discoveries and principles. Nevertheless, it affords many guarantees to the public. It removes from the town various industries, especially in regard to the bye-products, that are likely to give rise to a dangerous nuisance. It places these under strict surveillance. It focuses the cattle and the meat trade on one spot and renders the work of inspection easier and more likely to be efficacious. It also insures cleanliness. These are great advantages which the inhabitants of Marseilles have secured and upon which they are to be congratulated.

SOME TURKISH LAZARETS

AND OTHER SANITARY INSTITUTIONS IN THE NEAR EAST.

Means of Landing and Re-embarking the Pilgrims at the Lazaret of Camaran.—"Sambouks"—The Tug "Camaran."—The Landing Stages: the Two Jetties in the Bay and the Four Landing Piers for Pilgrims.

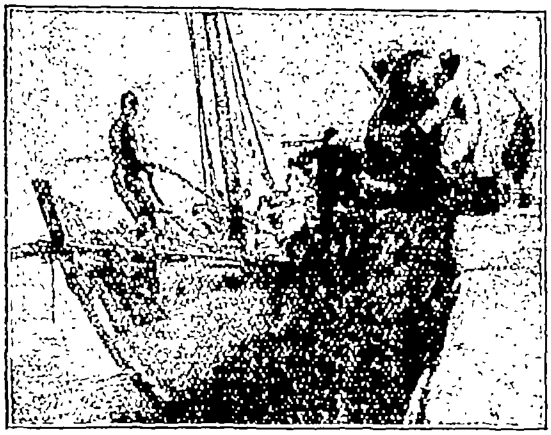
SINCE the pilgrims land at Camaran solely to please the sanitary authorities the latter have to provide means for taking them from the ship to the shore and back again to the ship at the expiry of their term of quarantine. It will be convenient to consider, first, the means of transport between ship and shore; and secondly, the jetties at which the pilgrims are landed.

(*a*) *"Sambouks" and the tug "Camaran."*—The pilgrims are conveyed ashore in native boats called "sambouks." These craft vary much in size; the largest are nearly fifty yards, the smallest only some ten yards, long. They draw from two to five feet of water. They can carry from 30 to 100 pilgrims, the number varying with the size of the boat and also with the amount of luggage that the pilgrims have with them. The Persians and Javanese carry always a large quantity of baggage, while Indians as a rule, and particularly the poorer amongst them, have very little. The lazaret has at its disposal 15 of these sambouks of different sizes. Each year a contract is made with the owners specifying the conditions of their engagement for the season. A small sambouk is seen in the accompanying illustration (Fig. 1). Formerly these boats sailed, or were rowed, from the ship to the shore. But since 1905 the lazaret has possessed a tug, called the *Camaran*, which tows the sambouks. The gain in time and in every other respect has been considerable. The tug is a small steamer of 34 tons and 25 horse power; she is some 20 yards long and four wide and can make from eight to nine and a half knots an hour. This steamer, which was built in Constantinople for the Board of Health, has already proved most useful.

---

[1] No. I. was published in THE LANCET of April 27th, 1907, p. 1163.

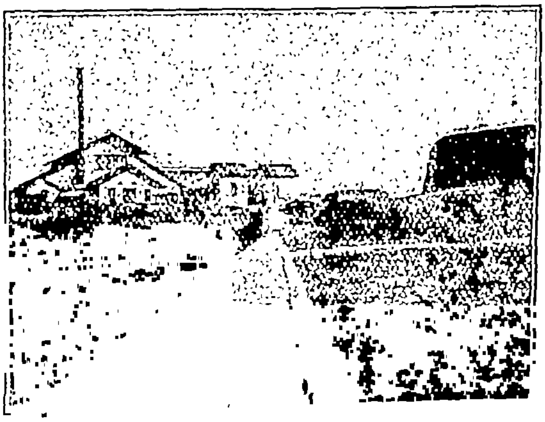
FIG. 1



Sambouk; pilgrims landing at the first landing stage.

(*b*) *The landing stages.*—The lazaret has six landing stages in all. Of these two are on the northern shores of the bay mentioned above and are used for all purposes connected with the administration of the lazaret; the other four are outside the bay, on the east coast of the island, and are used for the landing and re-embarking of the pilgrims. They may be briefly described in order.

FIG. 2.

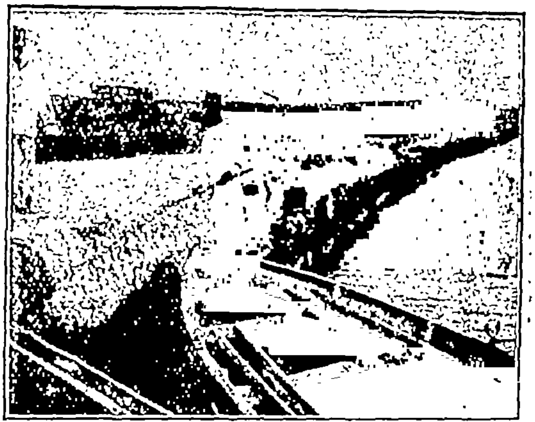


The jetée du parloir. Machinery building, laboratory, and "parloir."

The *Mervani jetty*, so-called from its proximity to the Mervani plain (i.e., the plain to the north of the bay), is a well-built jetty near the inner end of the bay. It was rebuilt in 1904, constructed of two lateral walls of dressed stone, filled in between with stones *à sec*—that is to say, without mortar. The entire length of the jetty is 132 metres and the width three metres. The head, which is about 11 metres square, is built of artificial concrete blocks; a two-ton crane stands at the end of the pier. The rails of the Décauville railway run to the jetty head, and also a five-centimetre pipe which conducts distilled water to a tap at the end of the pier by means of which portable tanks in the sambouks can be filled and good drinking water thus conveyed to ships that need it.

The *jetée du parloir*, so called because at its end is the "parloir," or small house where the interrogation of coasting ships takes place, is also on the northern side of the bay, but much nearer its entrance than the other. It was built in 1899, is 82 metres long and two metres wide, and is constructed of armoured cement, resting on arches and piers composed of concrete blocks. This pier, which is seen in Fig. 2, is in excellent condition and is one of the most frequently used of all the piers.

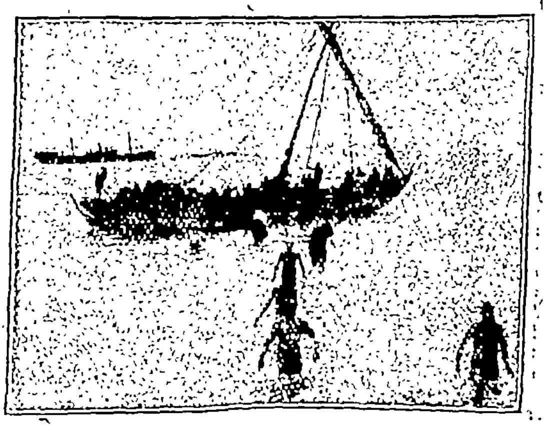
FIG. 3.



The first landing pier for pilgrims.

The *first landing stage* for pilgrims ("Birindji"), built originally of stone *à sec*, has been repaired with cement. Its full length is 96 metres and its width 3·10 metres, except at the head, which is 8·5 metres wide. Rails run to the pier head. This pier is in a bad condition and requires thorough repair. At its end there are about 70 centimetres of water at low tide and 1·70 metres at high tide, so that the sambouks can nearly always come up to the pier head; in summer, when the tides are exceptionally low, they occasionally find a difficulty, but only for the short period of quite low tide. *This jetty is well seen in Fig. 3.* It serves for the landing of pilgrims for the first and second camps or "cordons."

FIG. 4.



Pilgrims wading ashore to the fourth landing pier.

The *second landing stage* for pilgrims ("Iraki") is situated between the second and third cordons. It is of the same construction as the first but in a still worse condition of repair. Attempts have been made to repair it with boards and old rails, but it requires almost to be rebuilt, and the report of the Commission recommends, in addition, that it should be prolonged some five metres. Its present length is 48 metres and its width 3·80 metres, except at the head, which is 7·8 metres wide. It has no railway. This pier serves for the landing of pilgrims going to the second or third cordons.

The *third landing stage* ("De-Yr") is still further north. Its length is 117 metres and its width 3·40 metres; the head has completely disappeared. It is of the same construction as the other two and requires thorough repair and also lengthening by some 10 or 20 metres, the water at its end being very shallow. There is no railway along this jetty. It is used for landing and re-embarking pilgrims for the third and fourth cordons.

The *fourth landing stage* ("El-Kat-el-Kurush") is situated at the inner end of a bay, between the fifth and sixth cordons. It is 80 metres long and three metres wide, with a head four metres wide. It is built on eight arches and piles of dressed stone on a concrete base. It is in fair condition, but two of the arches are cracked and the pier is not nearly long enough. At low tide there are only 20 centimetres (about eight inches) of water at the head, and almost constantly the pilgrims landing here have to jump into the water up to their waists and wade ashore. They may be seen doing so in Fig. 4. It has been proposed to lengthen this pier by 60 metres, at an estimated cost of over £T.2700, but the inspection commission, for reasons which will be explained later, recommends the reduction of the long diameter of the lazaret to about one half of its present length, with consequent abandonment of the fifth and sixth existing cordons and also of this landing stage.

Proposed new landing stage.—At a spot between the present third and fourth cordons there is a small island a short distance from the shore and united to the latter by a sandy spit or causeway, except at high tide, when the island is completely cut off. The commission proposes to construct a new jetty, running over this causeway and out at the north end of the island. It will be almost in front of the second of the three disinfecting blocks to be described hereafter. There will thus still be four landing stages for pilgrims and, as will be shown in a later chapter, they will be quite as usefully and almost as symmetrically placed as at present.

When once the pilgrims are landed they are conducted, with their baggage, to one of the three disinfecting blocks. These buildings and the measures applied there will be described in the next article.

(To be continued.)

THE OUTBREAK OF PLAGUE IN JEDDAH.

(FROM THE BRITISH DELEGATE TO THE CONSTANTINOPLE BOARD OF HEALTH.)

THE outbreak of plague in Jeddah is beginning to subside. It will be recalled that the present epidemic, which is probably a revival of that which prevailed there last summer, began about Jan. 8th. At the date of my last letter[1] the total number of cases recorded down to Feb. 3rd had been 23, and that of deaths 22. Since then the weekly returns have been as follows:—

From Feb. 4th to 10th	10 cases,	10 deaths.
,, ,, 11th ,, 17th	20 ,,	19 ,,
,, ,, 18th ,, 24th	32 ,,	30 ,,
,, ,, 25th ,, March 4th ...	62 ,,	59 ,,
,, March 5th ,, ,, 10th ...	35 ,,	35 ,,
,, ,, 11th ,, ,, 17th ...	30 ,,	27 ,,
,, ,, 18th ,, ,, 24th ...	44 ,,	43 ,,
,, ,, 25th ,, ,, 30th ...	12 ,,	11 ,,
,, ,, 31st ,, April 7th ...	29 ,,	29 ,,
,, April 8th ,, ,, 14th ...	17 ,,	17 ,,
,, ,, 15th ,, ,, 21st ...	14 ,,	13 ,,

The total number of cases since the reappearance of the disease has therefore been 330 and that of deaths 317. It is a remarkable fact that, with the single exception of a fatal case of plague in a Javanese[2] pilgrim, the outbreak in Jeddah has been strictly confined to the native inhabitants of the town. A few other pilgrims did, however, develop the disease shortly after leaving Jeddah on their return journey home, and to these I shall refer again; but it is certainly noteworthy that, with plague epidemic, and fairly severely epidemic, in the town of Jeddah, the largest pilgrimage on record passed through that town twice—first, on the way to Mecca, and later after the completion of the Haj—and yet scarcely half a dozen of the pilgrims contracted the infection. I am inclined to attribute this relative immunity to the facts that the pilgrims do not stay long in Jeddah—not more than a few days as a rule, though in some instances it may be for much longer; that most of them lodge in houses specially built for the purpose, which are surveyed, cleansed, and whitewashed and put in order before the arrival of the pilgrims; and that those who are too poor to stop in houses camp out in the open air, where they are little exposed to the infection of plague either from contact with the inhabitants of the town or with rats.

There seems to have been much difficulty in applying measures for the suppression of the outbreak. The Arab inhabitants dread European interference more than the disease; the large majority of cases have only become known to the authorities after death and it is certain that many that recovered were never brought to the knowledge of the latter. Scarcely any of the cases have been removed to hospital. When a death from plague has become known the house where it occurred has been disinfected, but there must have been numbers of infected houses to which neither disinfection nor any other measure of prophylaxis was applied. Shortly after the revival of the disease in January it was proved beyond a doubt that rats were dying from plague and were in all probability the main channel by which the infection was being spread. A small reward, of the value of one penny, was offered for the bodies of dead rats, but there is no evidence at present that this measure led to any substantial results. The medical staff of the town was strengthened and an ample supply of plague prophylactic was furnished to them, but the latest reports show that it was almost impossible to induce the people to allow themselves to be inoculated. In some instances the opposition to the authorities took a more active form and violence was used. In one case a native woman—possibly interpreting too literally the injunction to heap coals of fire on others' heads—poured a torrent of hot ashes from a window on to the head of a disinfector who attempted to enter the house.

Outside Jeddah the following known cases of plague—which undoubtedly contracted the infection in that town—have occurred. Three persons arriving in Mecca from Jeddah developed the disease and two of them died. Two pilgrims on the return journey to India were landed at Aden with signs of plague and one of them died. Two other cases in pilgrims returning from Jeddah to the Yemen were landed at Camaran. Finally, among pilgrims returning northwards by the Suez Canal, two cases of plague have been observed, both at the Egyptian lazaret of El Tor. There have thus been, so far as is known, only nine instances in which the infection has been carried from Jeddah, and these have not given rise to any epidemic extension of plague elsewhere. Had Jeddah been as deeply infected with cholera as it has been with plague, it is easy to imagine how very different and how infinitely more serious to the rest of the world the result would have been.

Constantinople, April 24th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Our Hospitals and their Incomes.

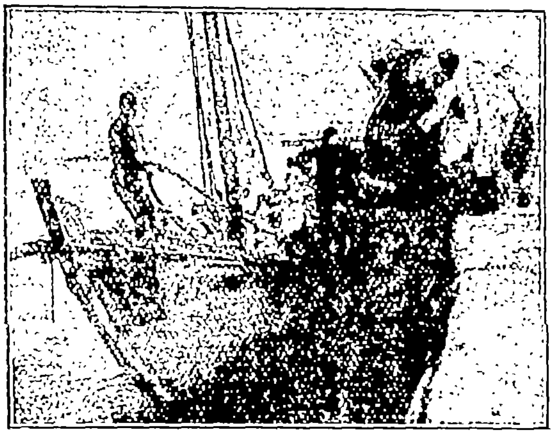
IN previous communications I have drawn attention to the comparative stagnation or actual diminution of the amount of subscriptions received by our hospitals, and on Friday last a most able article dealing with this matter and giving definite statistics appeared in the *Birmingham Daily Post*. The subject is one which must be of interest to all cities where there are many hospitals, and I have no hesitation, therefore, large quantity of baggage, while Indians as a rule, and particularly the poorer amongst them, have very little. The lazaret has at its disposal 15 of these sambouks of different sizes. Each year a contract is made with the owners specifying the conditions of their engagement for the season. A small sambouk is seen in the accompanying illustration (Fig. 1). Formerly these boats sailed, or were rowed, from the ship to the shore. But since 1905 the lazaret has possessed a tug, called the *Camaran*, which tows the sambouks. The gain in time and in every other respect has been considerable. The tug is a small steamer of 34 tons and 25 horse power; she is some 20 yards long and four wide and can make from eight to nine and a half knots an hour. This steamer, which was built in Constantinople for the Board of Health, has already proved most useful.

---

[1] THE LANCET, Feb 16th, p. 464.

[2] I should be glad of this opportunity to correct a slight printer's error which crept into my last letter. In column 2 of page 464 of THE LANCET, line 33, the word "Japanese" should be "Javanese." There are no doubt several Japanese Moslems; but during my stay in the Hedjaz last winter I did not come across, or indeed hear of, any pilgrims of that race. Javanese (a general term for pilgrims from the Dutch East Indies) are, next to Indians, usually the most numerous of all races in each year's pilgrimage.

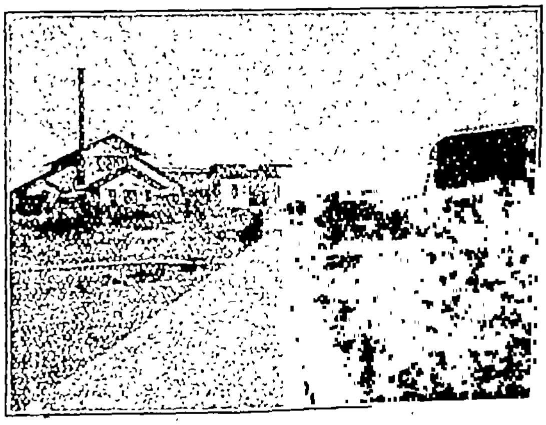
FIG. 1



Sambouk; pilgrims landing at the first landing stage.

(*b*) *The landing stages.*—The lazaret has six landing stages in all. Of these two are on the northern shores of the bay mentioned above and are used for all purposes connected with the administration of the lazaret; the other four are outside the bay, on the east coast of the island, and are used for the landing and re-embarking of the pilgrims. They may be briefly described in order.

FIG. 2.

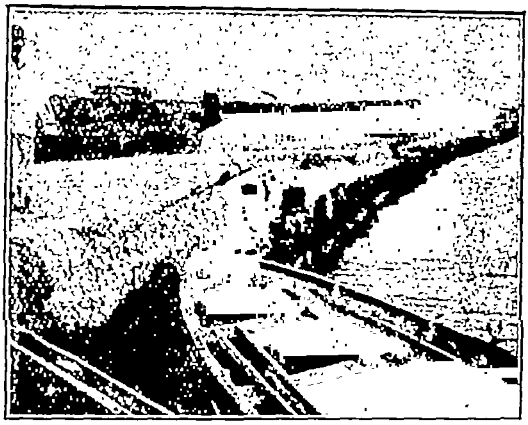


The jetée du parloir. Machinery building, laboratory, and "parloir."

The *Mervani jetty*, so-called from its proximity to the Mervani plain (i.e., the plain to the north of the bay), is a well-built jetty near the inner end of the bay. It was rebuilt in 1904, constructed of two lateral walls of dressed stone, filled in between with stones *à sec*—that is to say, without mortar. The entire length of the jetty is 132 metres and the width three metres. The head, which is about 11 metres square, is built of artificial concrete blocks; a two-ton crane stands at the end of the pier. The rails of the Décauville railway run to the jetty head, and also a five-centimetre pipe which conducts distilled water to a tap at the end of the pier by means of which portable tanks in the sambouks can be filled and good drinking water thus conveyed to ships that need it.

The *jetée du parloir*, so called because at its end is the "parloir," or small house where the interrogation of coasting ships takes place, is also on the northern side of the bay but much nearer its entrance than the other. It was built in 1899, is 82 metres long and two metres wide, and is constructed of armoured cement, resting on arches and piers composed of concrete blocks. This pier, which is seen in Fig. 2, is in excellent condition and is one of the most frequently used of all the piers.

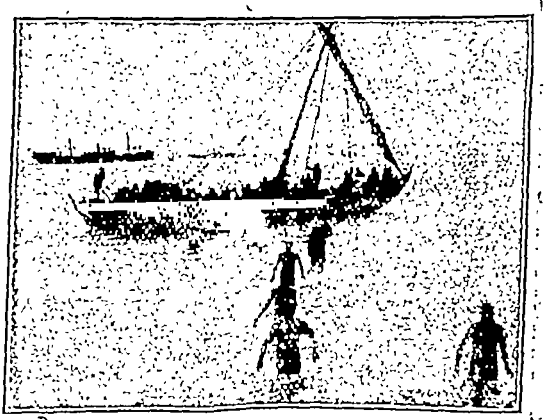
FIG. 3.



The first landing pier for pilgrims.

The *first landing stage* for pilgrims ("Birindji"), built originally of stone *à sec*, has been repaired with cement. Its full length is 96 metres and its width 3·10 metres, except at the head, which is 8·5 metres wide. Rails run to the pier head. This pier is in a bad condition and requires thorough repair. At its end there are about 70 centimetres of water at low tide and 1·70 metres at high tide, so that the sambouks can nearly always come up to the pier head; in summer, when the tides are exceptionally low, they occasionally find a difficulty, but only for the short period of quite low tide. This jetty is well seen in *Fig.* 3. It serves for the landing of pilgrims for the first and second camps or "cordons."

FIG. 4.



Pilgrims wading ashore to the fourth landing pier.

The *second landing stage* for pilgrims ("Iraki") is situated between the second and third cordons. It is of the same construction as the first but in a still worse condition of repair. Attempts have been made to repair it with boards very great extent by school influence, acting by the attendance at school of actual sufferers from the disease. Evidence is still wanting in St. Helen's that healthy "contacts" had introduced the disease to the schools. Measles was present at the end of the year and became epidemic in January. The number of families apparently affected had been about 930 and the number of cases among these was 1800. With regard to the exclusion of scholars living in infected houses in St. Helen's, there has never been any rule laid down by the health committee on the matter; the same general rule which applies to the exclusion of scholars from any cause is held to apply in St. Helen's. He recommended to the committee that it should be remitted to the secretary for elementary education and himself to draw up draft regulations for the exclusion of "contacts" with infectious diseases, similar to those adopted now by several authorities in the large towns.

April 30th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Infirmary.

DURING the past few years it has been customary for the board of management of the Cardiff Infirmary to issue, in connexion with its annual report, a supplementary report pointing out what are the needs of the institution as regards extensions and improvements. As a result many important additions have been made, including an operating theatre, casualty wards, and a new out-patient department. The last supplementary report suggested additional accommodation for 64 patients and other extensions to cost altogether £30,000. This would increase the accommodation to 250 beds. That this would not be too great is shown by the fact that there are constantly between 500 and 600 patients awaiting admission to the wards. For it must not be forgotten that the institution serves not only Cardiff but the large colliery districts of the Rhondda Valleys, Aberdare, and Merthyr, where there is a population approaching half a million persons. The appeal of the board has already met with a favourable response, Mr. John Cory, J.P., having promised to give £5000, provided the remaining £25,000 are subscribed within six months.

Meat Inspection by the Police.

It has been pointed out more than once that the difficulties of meat inspection in Cardiff arise almost entirely in connexion with meat which is slaughtered outside the borough. There are no private slaughter-houses in the town and inspection at the public abattoirs is a comparatively easy matter. Dr. R. Prichard, medical officer of health of the Llandaff and Dinas Powis rural district, which adjoins Cardiff, has recently made a suggestion for increasing the efficiency of the inspection in rural districts. He points out that the county police already take samples for analysis under the Sale of Food and Drugs Acts and administer the Contagious Diseases (Animals) Acts, and he proposes that they should visit the slaughter-houses on their beats and inspect any carcass that may be there. Dr. Prichard admits that the ordinary policeman is not a trained meat inspector, but he thinks "that a lesson or two from the county medical officer of health would be enough to enable him to distinguish diseased meat from what is not."

Isolation Wards of the Bristol General Hospital.

Special wards for the observation and isolation of suspected cases of infectious disease are now recognised as a necessary part of the equipment of general hospitals. Their absence must not only increase very considerably the anxieties of the resident staff but must also add to the difficulties and cost of administration. It is gratifying, therefore, to be able to record the completion of the isolation block which has recently been erected in connexion with the Bristol General Hospital. The building is of two storeys, each with a distinct entrance. On the ground floor are two wards for two beds and one for one bed. Between two of the wards is a nurses' duty room. Leading out of each of the larger wards is a circular sanitary annexe, containing water-closet and slop sink, with cross-ventilated passage. There is a portable bath for the use of all the wards. The remaining rooms include bedrooms for two nurses, bath-room, water-closet, and store room. The arrangement of the first floor is nearly the same as that of the ground floor, the difference being in the provision of a nurses' sitting room and the exclusion of a bath-room. The characteristics of modern fever hospitals, including the rounding of corners and the absence of ledges, have been applied to the wards, and the Gilmour hardwood doors have been used. These are made of small pieces of wood laid grain against grain and finished with an absolutely flush surface on both sides. There are fireplaces in the wards and other rooms, and the building is also heated with low pressure hot water pipes and radiators. The lighting is by electricity and the air can be extracted by an electrically driven fan. The cost of this building, which is quite separate from the main hospital buildings, was £5500, by no means an extravagant sum considering the accommodation which has been provided.

April 30th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Cerebro-spinal Fever in Edinburgh and Leith.

THIS fever is increasing in Edinburgh. According to the report submitted to the public health committee, 35 cases have occurred since the beginning of the month. The first case reported in the city was in January and in the month of March 31 supposed cases were reported and 18 deaths occurred. Of the 35 cases reported in April up to the date of the meeting (April 23rd) twice as many occurred in the old town as in the new town. During the month there were 24 deaths. The disease is also present in Leith, where the medical officer of health has been examining bacteriologically the throats and noses of persons who have been in contact with cases. The families of patients have been isolated and "contacts" who are not isolated have their noses and throats disinfected. The houses where cases have occurred are being thoroughly disinfected as well as the belongings of the inmates. There has been a reduction in the number of cases notified in Leith. Dr. W. Robertson's report will be waited for with unusual interest. There is no aspect of the disease so unsatisfactory and even alarming to the public mind as the knowledge that the channel by which infection enters the body is not known and that it is consequently impossible to know what special precautions to take.

Edinburgh Public Health Estimates.

It is always interesting to note the cost of administering the public health arrangements in a large city and the estimates for the incoming year, which begins on May 1st, have just been before the public health committee. The estimated expenditure amounts to £30,795. Some of the items going to the making up of this amount are: medical officers, £1765; sanitary inspectors, £3985; burgh engineer's department, £1005; reporting infectious diseases, £350; Colinton Mains Hospital, £19,350; Portobello Hospital, £410; and Campsie Convalescent Home, £955.

Royal Visit to Glasgow.

The visit to Glasgow of their Royal Highnesses the Prince and Princess of Wales was accomplished last week under the most favourable auspices. The city was profusely decorated in their honour, the weather was propitious, and notwithstanding the multitudes that kept holiday and crowded the streets there was almost an entire absence of serious accidents. Their Royal Highnesses during their visit, which extended from Tuesday to Friday, were the guests of Lord Blythswood at Renfrew. On the first day there was a reception in the St. Andrew's Halls; in the afternoon the new laboratories at the University were inspected and formally opened by the Prince. The next day was occupied in laying the foundation stone of the new Royal Infirmary, followed by a luncheon at the Municipal Buildings; while on the last day of their visit their Royal Highnesses visited Clydebank and inaugurated the new Rothesay Dock which has just been completed there. The scene at the University was exceptionally brilliant. A crowded and distinguished gathering representative of the academic, civic, and other interests assembled in the Bute Hall, where the ceremony of conferring the honorary degrees took place. Among those who received the degree of LL.D. were the Prince and Princess of Wales, the Lord Provost of Glasgow, Mr. Wyndham (late Lord Rector), Mr. Asquith (present Lord Rector of the University), and Professor J. G. McKendrick. The degrees were conferred by Lord Kelvin, Chancellor of in touching upon the matter again in the light of the extended information so recently provided, more especially as the conclusions which our leading daily paper draws from the investigations of its contributor are open to some doubt. Taking five of our principal hospitals, the General, the Queen's, the Women's, the Children's, and the Eye Hospital, it appears that 20 years ago (1886) the total income of the five was £34,069 and last year (1906) it amounted to £54,825. In 1886 the moiety derived from subscriptions was £12,963, and in 1906 this moiety had increased to £17,416—that is, in the former year the subscriptions formed a little more than 35·1 per cent. of the total income and in the latter year the percentage had fallen to about 30·7. In other words, there has been during the past 20 years a relative diminution of the subscriptions as contrasted with the total income. During the same period the number of in-patients received into the five hospitals has increased from 7134 to 10,297, and the number of out-patients from 10,297 to 159,032. One of the inferences drawn from these facts by the writer of the leading article in the *Daily Post* is that as the number of subscribers and the amount of subscriptions are falling off some of the committees should "concentrate their attention upon the acquirement of new subscribers," and he urges that nothing but a personal canvass will produce the desired effect. It is frequently stated that "the number of persons capable of giving a regular subscription to one or more institutions is far larger than is accounted for by a perusal of the subscription lists," but the evidence upon which this statement is made is not quite clear, and it by no means follows that because a given person has a certain amount of income or lives in a certain style he has any money which he can devote to hospital support, for frequently he has to spend the whole of the income he makes in maintaining those conditions of life which enable him to gain the income. Moreover, in considering this question of the relative diminution of hospital support by persons who have good average incomes, it must not be forgotten that the number of hospitals, dispensaries, and other charities is continually increasing, and taking the case of Birmingham the actual increase in the amount of subscriptions during the past 20 years as shown by the returns of the five hospitals referred to does not give a complete idea of the total increase of subscriptions during the whole of that period, for numerous other charities on various scales have been established or enlarged and their necessities have caused an expansion of the area over which subscriptions are distributed. It may still appear when statistics are available that taking all the newer institutions into consideration the amount of subscriptions is still showing reduction as contrasted with the number of patients treated and the total amount of income. If this should prove to be so the fact would not be surprising, for it must be remembered that the portion of the community from which subscriptions are drawn finds that the expense of living continually increases. We are in a period of extravagance, not only in public but also in private life, and at present there is no sign of a movement which shall tend to the reduction of those so-called "necessary" expenses which absorb money that otherwise might be devoted to charities. Further, the classes from whom hospital subscriptions are expected are feeling more and more the burden of taxation. Their incomes are taxed in unreasonable proportion for national purposes, they are taxed for the education of other people's children, and for the more or less complete maintenance of many of them. In these circumstances it is scarcely surprising that voluntary subscriptions for charitable purposes do not greatly increase, for it may be taken as certain that the more people are forced to do the less they will do in a voluntary manner. Looked at from this point of view it does not appear probable that a personal canvass will be very effectual in raising the amount of the subscriptions for any length of time, for it is not likely that the causes which militate against increase will diminish. In these circumstances, then, it becomes interesting to inquire into the amount given to the hospitals by the more popular Hospital Saturday Fund, which may be looked upon as the subscriptions of those who make most use of the hospitals. This Fund, under the admirable management of the committee, has considerably increased during the past 20 years, and it is therefore the more surprising to find from the statistics provided that the portion devoted to the five hospitals has diminished as contrasted with their total income. In 1886 the amount given from the Hospital Saturday Fund to the five hospitals under consideration was £4583, and in 1906 it had increased to £6975, or, in other words, in the earlier year it formed a little less than 13·5 per cent. of the total income and in 1906 a little more than 12·7 per cent. There is no doubt that the remainder of the Hospital Saturday Fund is well utilised, but in the circumstances it may be urged fairly that more of it might with advantage be devoted to the maintenance of the hospitals.

The Health of Birmingham.

For a considerable period we have rejoiced in a low death-rate and some of the more sanguine of us were hopeful that the time had come when the low rate would be practically permanent. We are inclined to feel disappointed, therefore, to find from the medical officer's report that whilst it is still low, 19·9 per 1000, it is higher than it has been during the first quarter of the year since 1904, but there is consolation in the knowledge that it is still below the average for the first quarter of the past ten years, which is 20·3 per 1000. Part of the increase appears to have been due to the very varying and inclement weather, for the number of deaths from pulmonary and pleuritic inflammations has been large. Measles also has been more than usually fatal, and the scarlet fever from which we have been suffering appears to have become more virulent, for its death-rate has risen to 4·7 per cent. Diphtheria and typhoid fever are also more prevalent than is desirable. The birth-rate for the quarter was only 29 per 1000.

The Notification of Consumption at Coventry.

Coventry has decided to follow Birmingham's lead and its sanitary committee has made arrangements for the voluntary notification of pulmonary tuberculosis. It was also decided at a recent meeting of the Coventry city council that Birmingham should be approached as to the terms on which Coventry might be allowed to utilise the proposed sanatorium which is to be established near Cheltenham, where it is suggested that 40 chalets should be erected as soon as possible.

April 30th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Health of Liverpool.

THE birth-rate in Liverpool for the week ended April 20th was 35 per 1000. The death-rate was 20·1 per 1000, compared with a mortality of 23·5 per 1000 a year ago. The zymotic cases in hospital were: small-pox, 4; scarlet fever, 372; typhus fever, 7; typhoid fever, 42; diphtheria, 37; and in isolation, 63. This time last year the epidemic of measles was accountable for the higher death-rate.

St. Helen's Hospital: Workmen's Contributions.

The thirty-fourth annual report of the St. Helen's Hospital showed that, in spite of the large growth of expenditure consequent on the enlargement of the hospital, the income for the year had grown correspondingly owing entirely to the highly satisfactory increase in the penny-a-week contributions of the working men, which amounted to £3198, against £2478 in the previous year. During the year 829 patients had been treated, against 707 in the previous year. The hospital has sustained a great loss by the death of Sir David Gamble, Bart., who was one of its warmest supporters.

Epidemic of Measles at St. Helen's.

The medical officer of health (Dr. J. J. Buchan) has submitted a lengthy report on the epidemic of measles among school children to the St. Helen's health committee. He stated that the history of measles during the last 30 years in St. Helen's showed that the disease had been almost constantly present, breaking out in epidemics of greater or less severity every two or three years. The epidemics exhibited themselves in two forms, a major and a minor variety. In the major epidemics the disease had appeared in the earlier part of the year and assumed a more virulent type than in the minor ones, which contributed less to the death-rate. The disease was spread by personal contact with the sufferer, particularly in the early stage of the illness, the infection then being apparently given off by the discharges from the throat, nose, and lungs. The actual cause of the disease had not so far been discovered. Measles appeared to be spread to a of great uneasiness might very possibly be caused in the city from the fact that a sanatorium for tuberculosis was constructed upon one of the sources of the water-supply." This decision of the Local Government Board was received with great satisfaction by the citizens of Cork generally because, apart from danger altogether, they strenuously objected to the disgusting idea of being called on to drink water which had received the dejecta and sputum of consumptives.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Abortion.

AT a recent meeting of the Obstetrical Society an important discussion was commenced upon abortion, more especially the criminal variety. M. Boissard, the first speaker, gave an account of cases of abortion which had come under his care in his wards at the Tenon Hospital. He stated that the number of criminal abortions was constantly increasing and that in a very disquieting fashion. He admitted that—in the absence of a direct history from the patient, which, of course, was difficult to obtain—the abortion had been criminally brought about; that he relied for diagnosis of criminal intent upon a rise in the temperature and signs of infection. Spontaneous abortion is not, as a rule, due to infection and does not give the above-mentioned symptoms. For treatment he advised active measures and immediate curetting. M. Tissier also spoke of the increase in the number of abortions and blamed the light view which was taken of the practice by the magistrates and the general laxity of morality which was encouraged by certain modern views according to which limitation of families was not a crime. Among the higher classes, he said, women had no shame in avowing that they had had abortion procured, as if it were quite the natural thing to do. The class which made up hospital patients was, however, much more reticent. M. Tissier thought that the society should organise a strong protest against such practices. M. Blondel agreed with the two former speakers. He added that the airy way in which abortion was looked upon in Paris made foreigners think that it was permitted in France. For his own part he had every year to send away from his consulting-rooms sundry English women, both married and unmarried, who had crossed the Channel simply to have abortion brought on, and who in some cases had the impertinence to allege that they had been sent by their medical attendants.

Congress of Medical Practitioners.

A congress of medical practitioners was held at Paris from April 12th to 14th. 14,000 medical practitioners had sent in their names as approving of the objects of the congress. 100 medical societies, some of them having many thousands of members, such as the Association des Médecins de France, the Union des Syndicats Médicaux, and the Concours Médical, had subscribed to the funds of the congress. Many members of the Faculty of Medicine and of the Academy of Medicine took part in the discussions upon the question of the reform of medical education, and the press in general has treated the congress as a remarkable event which will be a landmark in the history of French medicine. The opening discussion dealt with medical education and it was pointed out that many reforms might be made in the education given at hospitals. The hours of visits and of lectures in the wards of a hospital should be so arranged (*échelonnées*) that the student could attend several during one term. The State faculties of medicine should be able to apply to private cliniques for clinical material as is the custom in provincial schools. The income of the various medical faculties is extremely small. It is some 20,000,000 francs inferior to that of Germany and the State ought to be applied to for subsidies. The number of professors is not sufficient for the number of pupils and the congress adopted unanimously a resolution stating that the hospital should be the centre of instruction from the point of view of clinical medicine and therapeutics. As to reforms of teaching in the faculties the general view taken was that these faculties would honour themselves by engaging well-known personalities for their various posts and for their educational work. The mode of supplying professors was variously looked upon, some demanding the institution of *privat-docenten* as in Germany and adding that this plan could perfectly co-exist with the present state of matters. The question of the reform of the *concours de l'agrégation* was lightly touched upon. Other questions debated were that of payment of a professor by his pupils and that of absolute freedom of choice being allowed to every member of a friendly society to choose his own medical man and his own druggist. Another question debated was that of vacation classes and post-graduate courses of lectures (*l'enseignement complémentaire*). Finally, the congress demanded a weekly day of rest for medical men or else the fixing of a tariff which would make it legitimate for double fees to be charged for Sunday work. An enormous quantity of questions were debated more or less fully, and if many of them have not found a solution it can nevertheless be stated that this first meeting of medical men has been of great use in the debating of such questions and also shows that they occupy the attention of very many medical men. It is probable that at the next meeting the matters will have ripened and that very likely some practical solutions will be arrived at.

Constipation and Hypothyroidia.

At the meeting of the Biological Society held on April 13th M. Lévi and M. H. de Rothschild communicated a paper in which they stated that they had treated sundry cases of constipation by thyroid medication. The youngest case was aged three and a half years and the oldest 63 years. All the patients showed symptoms of hypothyroidia, such as migraine and chronic rheumatoid arthritis.

Typhoid Fever caused by Oysters.

At the March meeting of the Biological Society M. Netter reported a series of cases of typhoid fever in which the evidence of the disease having been caused by oysters is quite irrefutable; the facts were communicated to him by Dr. Villanex. Two families living at a distance of two kilometres apart divided a basket of oysters from the Olonne beds; these were eaten by both families at their *déjeuners*. The oysters were fresh, in fine condition, and were pronounced excellent. In the first family there were 11 persons, of whom six partook of the oysters; in the second nine, of whom five ate them. Of the 11 persons who had eaten them ten became ill (i.e., 91 per cent.) and four developed typhoid fever (i.e., 36·4 per cent.); there was one death (i.e., 10 per cent.). None of the other nine persons who did not eat any oysters became ill.

April 29th.

COPENHAGEN.

(FROM OUR OWN CORRESPONDENT.)

Death after a Tracheal Operation in which Cocaine was Used.

AT the last meeting of the Danish Oto-Laryngological Association Professor E. Schmiegelow communicated a note on a case in which he had removed a grain of maize from the right bronchus of a girl, four years of age, by means of Killian's superior tracheoscopy. The foreign body had been in the bronchus for about eight days, when the little patient came under Professor Schmiegelow's care. It could be easily seen after the administration of chloroform but the extraction proved very difficult, partly because no suitable hooks were available for use. More than an hour elapsed before the attempts were successful, and it was necessary to apply between five and six cubic centimetres of a 10 per cent. solution of cocaine chloride to the mucous membrane of the respiratory tract. Soon after awakening from the anæsthesia the patient became very restless and shortly afterwards convulsions set in. Some hours later she died from what Professor Schmiegelow did not hesitate to diagnose as acute cocaine poisoning. Dr. P. Jetens Hald called attention to the cases of death from acute cocaine poisoning observed up to now in patients who had undergone tracheo-bronchoscopy. There were at least three deaths on record, two in America and one in Switzerland.

A New Operation for the Removal of the Urinary Bladder.

At a recent meeting of the Medical Society of Copenhagen Professor Thorkild Rovsing read a paper on an improved operation for the complete extirpation of the urinary bladder. There were great disadvantages connected with the older methods, especially because the way in which the ureters the University. After this ceremony the new laboratories were inspected and declared open. These buildings—one housing the departments of physiology, forensic medicine, and materia medica, and the other the department of natural philosophy—have been in the course of erection for several years. It is interesting to note in this connexion that it is exactly 60 years since Lord Kelvin, in a cellar of the old college, inaugurated the first physical laboratory for students in Europe. Afterwards luncheon was served in the large natural philosophy laboratory which had been specially prepared and decorated for the occasion. The scene at the laying of the foundation stone of the Royal Infirmary next day was no less brilliant. It will be recollected that the infirmary erected in 1791 was found to have become out of date in all important respects and it was resolved to rebuild it entirely and to dedicate it as a memorial to Her late Majesty Queen Victoria. It was the foundation stone of the first block under this new scheme which was laid on Wednesday. In laying the stone the Prince made a graceful reference to Lord Lister whose early work in antisepsis was carried out in this infirmary and whose eightieth birthday has just been celebrated. Before leaving the infirmary the Prince handed £100 to the chairman of directors for the reconstruction scheme. Both at the University and the infirmary much gratification was caused by the evident and sympathetic interest of their Royal Highnesses.

Aberdeen Royal Infirmary.

The staff of resident medical officers at the Aberdeen Royal Infirmary has now been increased from four to six. According to the old arrangement each medical officer had charge of a medical and a surgical ward. It is now proposed to give each resident charge for six months of a surgical ward and for another six months of a medical ward. The newly-appointed residents are Dr. N. S. Gilchrist, Dr. G. Mitchell, and Dr. A. T. Pirie, while Dr. J. Raffan, one of the retiring residents, has been appointed for a further period of four months.

Cerebro-spinal Fever.

The outbreak of this fever in Aberdeenshire has now, to all appearance, been checked. In all there have been six deaths. Only one case has been notified in the city.

Diseases of the Eye in School Children.

In connexion with the serious epidemic of conjunctivitis and trachoma among the children attending the board schools in Aberdeen during the past winter a deputation from the directors of the Ophthalmic Institute had an interview during the past week with the members of the administrative committee of the school board. It was pointed out by the deputation that owing to the serious epidemic much additional work and expense had been thrown upon the institution, the cases having run into many hundreds. The board considered that but for the voluntary offices rendered by the institution it would have been necessary to appoint a medical officer of its own, and it therefore agreed to give a grant of £40 to the institute.

Medical Questions at the Trades Congress.

At the Scottish Trades Congress held in Aberdeen, a motion by one of the Aberdeen representatives—

> That this Congress is of opinion that the law in regard to the question of vaccination should be the same in Scotland as it is in England, that the conscience clause should be or ought to be as essential to a Scotchman as it is to an Englishman—

was carried by a large majority. At the same Congress Mr. Hendry Brechin moved:—

> at in the opinion of this Congress the Education (Scotland) Acts should be amended so as to make it compulsory on school boards to provide for the medical examination of all children on entering school, and periodically throughout their school life; and to give powers to school boards to provide medical appliances for the correction of physical defects where necessary.

The motion was unanimously adopted.

April 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Anatomical Teaching in Dublin.

A RESOLUTION was recently adopted by the North Dublin union which with other provisions directed that notices should be posted in all the wards and corridors warning the inmates that if they did not give specific directions to the contrary their bodies—if they died—would be sent to the schools of anatomy. This resolution has caused much trouble in the anatomical and surgical schools. Dr. J. C. McWalter, who is a guardian, said that it would be a cruel and disgraceful thing to frighten poor people coming into the union by drawing their attention to the matter. Dr. A. Fraser, professor of anatomy at the Royal College of Surgeons, has addressed the following letter to the board of guardians:—

> SIR,—I am directed by the anatomical committee, which represents the Medical School of the Catholic University, the Medical School of Trinity College, and the Medical School of the Royal College of Surgeons in Ireland, to draw the attention of your board to the very serious consequences which will inevitably follow from the stringent application of the motion which they passed on the 17th inst. These consequences, the results of which cannot be foreseen, may be briefly summarised as follows: (1) The absolute ruin of the three Dublin medical schools; (2) thus depriving young Irishmen of obtaining a medical education in the capital city of their own country; (3) the disastrous effects on the city generally from the enforced banishment of the young Irishmen who intend to follow a medical career. The representatives of the three medical schools are confident that the necessity on their part of forwarding this letter would never have arisen had the guardians been aware of the consequences of the passing of their motion, and they venture to express the hope that the guardians may be kind enough to reconsider their decision. Should it be thought necessary the committee will gladly forward a printed statement to each of the guardians, or a deputation can be arranged to wait upon them, and afford them any further information they may require.

Cerebro-spinal Fever in Belfast.

At a meeting of the public health committee held on April 24th it was reported that for the week ending April 20th the death-rate from all causes had been 23·9 per 1000. 36 cases of cerebro-spinal fever had been notified during the week, as compared with 24 in the previous week. Altogether, up to April 24th 337 cases have been reported in Belfast with 227 deaths. Of the 107 patients in Purdysburn fever hospital up to April 24th, 43 were suffering from cerebro-spinal meningitis, and ten out of 12 deaths occurring during the week in that institution were caused by that disease. Since the 24th up to to-day (April 30th) six more cases of cerebro-spinal fever have been admitted to Purdysburn city hospital.

Bangor Cottage Hospital.

A committee appointed at a public meeting held in Bangor, county Down, on April 22nd to confer with Lady Clanmorris regarding the carrying on of the work of the hospital in that town, has handed in its report, and at a public meeting called on April 24th it was decided to take over the Cottage Hospital with equipment as from June 1st next and to do all things necessary for administering the affairs of the institution, including the appointment of officers, board of management, and committee. Further, it was agreed that the committee should act on behalf of the town and district in regard to providing a new hospital suitable to the needs of Bangor and the neighbourhood.

The Belfast Health Commission.

The sittings of the Belfast Health Commission were resumed on April 25th and since that day evidence has been taken among others from the following in reference to the water-supply of Belfast: Professor J. L. Smith, Professor W. St. C. Symmers, and Mr. L. L. Macassey, C.E., consulting engineer to the Belfast water commissioners.

The Proposed Sanatorium for Cork Consumptives.

The Local Government Board has given its decision with regard to the application of the Cork conjoint hospital board for permission to erect a sanatorium at Myshall. It will be recollected that the proposed site is on the bank of the Tullig river, which is a tributary of the Lee, from which the citizens of Cork derive their water-supply. At the inquiry held last February it was pointed out that patients would be likely to expectorate into the river and that the disease might in that way be communicated to the inhabitants of Cork. Furthermore, it was contended that no matter what steps would be taken to purify the sewage its conveyance into the river would be a constant menace to public health. Further expert opinion has now been taken with regard to sewage disposal and the possibility of tubercle bacilli surviving sufficiently long in the water to prove a danger to Cork but no unanimous views were arrived at. In the course of giving its decision the Local Government Board stated that it "does not, however, consider that it would be warranted in making a Provisional Order in view of the very strong opposition of the citizens of Cork as put forward by their elective representatives, and while, as already stated, it thinks that the prospect of contamination of the water-supply is very remote, it realises that a feeling

January when the thermometer registered 26° Centigrade below zero. These cases, it is gratifying to add, responded well to treatment and were "sent on their way rejoicing."

April 28th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Experiments on the Prevention of Cerebro-spinal Meningitis.

THE epidemic of cerebro-spinal meningitis still continues on a small scale, but active and, as it is believed, sufficient measures have been instituted for its suppression by the recent regulations of the sanitary department. When a case has been notified all the members of the household are subjected to a procedure which, according to the experiments of Dr. Jehle, can be relied on for destroying the diplococcus meningitidis which is the special organism of the disease. The procedure consists in spraying a liquid containing "pyocyanase," a preparation of the bacillus pyocyaneus, into the naso-pharynx of the patient. It has been found that the number and the virulence of the diplococci obtained from infected nasal discharge were diminished by 50 per cent. within 24 hours after the application of the pyocyanase and that all the diplococci disappeared in from 48 to 60 hours. The same treatment has been recommended by the Government officials in the country hospitals and disinfection of all wearing apparel, bedding, and dwelling houses is done free of charge by the various municipal authorities. The number of cases reported since Jan. 1st is 112, with a mortality of 16 per cent., in spite of all modern means of treatment. In order not to increase the alarm felt by the public in regard to this disease the reports are not published in the newspapers.

Adulteration of Food.

The monthly report of the health officer of Vienna deals this time with some criminal proceedings instituted against certain "honest peasants" for adulterating food with substances injurious to the health of the consumer. Milk is one of the articles which is subjected very often to such treatment. In seven cases considerable quantities of milk from a large dairy were found to contain such additional ingredients as starch (in quantities varying from 5 to 12 per cent.) or even chalk. In a few other instances in which the milk contained numerous germs and micro-organisms the discovery was made that it was "augmented" with water from a certain spring supposed to be very beneficial on account of its composition, and bacteriological examination of the water from that spring showed the presence of numbers of micro-organisms. Meat was painted with rosanilin to give it a better appearance, and fresh-water fish, used here especially just before Easter, were treated by injections of air into the tissues to make them look plump. Sweetmeats were found in several instances coloured with anilin dyes and pigments containing lead. Cocoa powder and red pepper were adulterated with brick-dust, while flour and sago were frequently mixed with fine white sand to increase the weight. The strict supervision of the daily market for provisions has been in operation for only a few years but the results have been very satisfactory as regards the purity of the articles of food supplied to the inhabitants of the city.

A Displaced Tooth in the Nasal Cavity causing Fœtid Vomiting.

An unusual case of great diagnostic and anatomical interest was shown by Dr. Glas at one of the recent meetings of the Vienna Medical Society. The patient was a lad, 19 years of age, who when a child had once fallen violently on his nose. He complained of very fœtid eructation with occasional vomiting of green, foul smelling masses. The examination of the sputum, fæces, and a test breakfast gave no clue to the cause of this. In the nose, however, a curious condition of things was found. Between the left lower and the middle turbinated bone and the septum there were greenish-yellow, gangrenous, fœtid, friable masses, which indicated the presence of either a foreign body or an ulcerating neoplasm. After considerable difficulty and much bleeding a hard body was found and removed. This proved to be a canine tooth, which undoubtedly had been pressed into the nasal cavity by the fall already mentioned. The examination of the teeth of the patient showed the absence of the canine tooth, no interval existing between the first premolar and the lateral incisor of the left side. After removal of the rhinolith the fœtid vomiting ceased at once. The case is a great rarity, only two similar instances of displaced teeth forming rhinoliths having been recorded hitherto. In this patient the vomiting of the green masses was so difficult to explain that serious abdominal disease was suspected.

A New Hospital for Lupus.

The plans of a new hospital for lupus were a few days ago approved by the Minister of the Interior and the building will be finished in a short time The present hospital for lupus, which has only 12 beds and four Finsen lamps, has for some time been unable to provide accommodation for the numerous patients who come from all parts of the empire seeking admission. The new hospital will have accommodation for 90 in-patients, a large out-patient room, 20 Finsen lamps and x ray apparatus, a surgical department, a research laboratory, and a pavilion with 40 rooms for the reception of out-patients who do not require to keep their beds but who on account of their disease are debarred from walking in the streets or public gardens. This "home," or "refuge" as it is called, will be connected with the large garden of the hospital so that the residents in the home will be able to obtain recreation and fresh air without mixing with other people. The expenses of this hospital for lupus are defrayed partly by the State and partly by voluntary contributions.

Health of Vienna.

A recent weekly report of the Board of Health shows an enormous increase of the infectious diseases, which have reached a level hitherto unattained since regular records were instituted. Measles and its complications were responsible for 68 deaths, whilst 312 new cases were notified. Scarlet fever was fatal in seven instances, whilst 73 new cases were reported. Typhoid fever and croup were each fatal in six cases. The general mortality was 21 per 1000, or 20 per cent. more than the yearly average. Not a single case of cholera, dysentery, or small-pox has been recognised during the last eight weeks. Pulmonary tuberculosis carried off 143 patients and neoplasms caused 63 deaths in one week. A sudden rise in the number of cases of erysipelas was noted but could not be traced to a definite cause; 37 fresh cases distributed throughout all parts of the city were reported and three of these were fatal. Pertussis was prevalent in the southern parts of the city, where 63 cases, with a mortality of 5 per cent., were reported. A comparison of the vital statistics for March with those for the corresponding weeks of the last five years is unfavourable for the present year, the morbidity being higher by 50 per cent. and the mortality by 25 per cent. Climatic reasons have been made use of to explain the facts. The barometric pressure has been low for many weeks and the amount of bright sunshine during April was so much less than in March that the virulence of the bacteria is supposed to be increased by these atmospheric conditions. Another very remarkable fact is the diminished incidence of cerebral hæmorrhage. It is pointed out in the report that the figure is extremely low, but no attempt is made to draw conclusions from the fact.

April 27th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The Annual Report of the Budapest City Hospitals.

AMONG the varied contents of this highly interesting and scientifically compiled huge volume, I think that the following data are worthy of being brought to the notice of the English-reading medical public: 1. The results of serum therapeutics in the St. Ladislaus Hospital. Antidiphtheritic serum was applied in 494 cases. The percentage of recoveries was different in different months of the year and it seemed that it was the laryngeal complications which chiefly influenced the recovery-rate. Amongst all cases (494) there were 163 attended with laryngeal complications (i.e., 31 per cent.), and of the patients 47 (or 9 5 per cent.) died and 447 (or 90 5 per cent.) recovered. It is noteworthy that the author (Dr. Sigmund Gerlóczy, director of the hospital) states that the results would have been still better if were disposed of was anything but satisfactory. Whether the ureters were left in the wound produced by the operation or were implanted into the rectum, the result was in either event very often disastrous, because both methods almost necessarily led to ascending infection of the kidneys, the first method also very often causing cicatricial stricture of the ureteral orifices, with subsequent hydronephrosis. The chief original feature of Professor Rovsing's operation was the way in which he avoided the above-mentioned dangers. After the complete extirpation of the bladder he frees the ureters entirely by dissection for a long distance and he then makes a buttonhole-like opening in either lumbar region, extending from the peritoneal cavity to the skin of the back. Through this slit the ureter of the corresponding side is pulled out so far that the mucous membrane of its outlet can be sutured to the skin in the lumbar region surrounding the slit. Stricture of the ureteral outlets is thereby avoided. In order to collect the urine trickling out from the ureters a specially constructed silver vessel is applied in either lumbar region round the ureteral openings, and from these vessels the urine flows down through indiarubber tubes to a portable urinal of the ordinary sort. This appliance has proved satisfactory as a means of escape for the urine and the patient has been entirely free from any urinous smell. Dr. Niels P. Ernst suggested a possible improvement in the operation. He asked if it would not be well to pull the ureters out through the buttonhole for a distance of about one inch or so and then to encircle them with a flap of the surrounding skin, so that a penis-like prominence was created in either lumbar region on the top of which prominence the ureter had its outlet. He thought that it would be easier in this way to make sure in all cases of the sufficiency of the silver vessel than when this latter had to be applied to a level or perhaps even a hollow surface

The Royal Frederic Hospital.

On March 30th at the Royal Frederic Hospital the 150th anniversary of its foundation was celebrated. As this hospital has been connected with the University of Copenhagen for the last 100 years or more for the clinical instruction of the students it plays a prominent part in the recollection of all Danish practitioners. When first established it was certainly better than most European hospitals of that time, but it is not in accordance with modern ideas, and the addresses delivered at the festival did not express deep sorrow at the prospect that the venerable institution would soon exist only in memory. In a few years the University will possess a model hospital that is now being built in the north of the city at considerable expense. This new hospital is nearly on the same system as the Virchow-Krankenhaus in Berlin. It will take the name of Rigshospitalet (the State's Hospital), so that even the name of the Royal Frederic Hospital will disappear.

The Royal Board of Health.

Considerable sensation has been created by the somewhat abrupt manner in which the Royal Board of Health has come to an end after having carried out its important task for more than a century. The board has till now been the highest authority on all hygienic, medico-legal, and medico-political questions. Nine of our most prominent medical men and two apothecaries were nominated by the King as members of the board, an office that was entirely honorary and not endowed with any salary whatever. All difficult medico-forensic questions were referred to the board and it had the supervision of the professional conduct of all Danish practitioners and apothecaries, the superintendence of the lunatic asylums of the State, &c. Until five years ago, when the present Minister of Justice became a member of the Cabinet, the decisions of the board in questions involving expert opinion were always accepted by the Minister of Justice, under whom our whole medical system is placed. But in the course of the last five years the board had been insulted over and over again, the Minister either neglecting to ask for its opinion on important questions of medical interest, such as the legislative enactments dealing with tuberculosis and prostitution, or else acting contrary to its advice. As the members were nominated directly by the King they complained to him of the Minister in December, 1906. The Minister's reply was a sarcastic speech in Parliament. The members of the board then expressed an intention of resigning, but the Minister answered that the board could not be allowed to retire from office unless it could secure successors willing to take the places which would become vacant. This last insolence finally proved too much and not long ago the members resigned in a body, disregarding the Minister's threat that he would call them to account for their illegal behaviour. It has been impossible for the Minister to find medical men willing to serve on a new board and he has been obliged to acknowledge his defeat by nominating a "homo novus" as medical adviser to the Government.

April 27th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

"La Croce Verde."

"THE Green Cross" is an offshoot of the Red Cross and in the great Italian centres is already justifying its inception and organisation by prompt and effective work. Both associations, indeed, have their prototype in the "Misericordia"—a purely Tuscan institution enlisting in its humane service every member of society, high and low, rich and poor. With the growth of population and the increasing complexity of life, however, the "Misericordia" has proved, even in its limited area (Florence, Pisa, Leghorn, Lucca, Siena, and Arezzo, to mention its chief centres in Tuscany), inadequate to the calls upon it, and so we have of late years witnessed the Red Cross going outside its professed military scope and now the Green Cross supplementing it in turn. In Milan this latter has been organised with special forethought and efficiency, thanks to medical sympathy and coöperation, and its *personnel*, recruited mainly from the young of both sexes of the humbler class, is—again thanks to medical inspiration and support—trained to the work by systematic instruction in "first-aid" service of every kind. Philanthropic physicians and surgeons give evening lessons in rudimentary anatomy and surgery and in what may be called the "clinique of the pavement" or the "therapeutics of the thoroughfare," so that in cases of accident or sudden lesion (all too common in the seething centres) the patient is intelligently dealt with and transported with the least possible delay to the dispensary or hospital. The interest taken in the work by the shop girl or the factory hand is at once gratifying and reassuring—gratifying as showing the reserve fund of good latent in the class so often prolific of the "hooligan," and reassuring for its demonstration of a remedy for that characteristic development of overcrowded cities. In truth, the "hooligan," or his Italian equivalent the "teppista," is as often as not the outcome of sheer animal spirits chafing under restriction and only requiring an outlet for the energy he revels in to become an agent of good instead of evil. This fact, borne in upon the organisers of the Italian "Green Cross" by daily experience, has an interest of its own for the social reformer and may yet inspire other efforts for the humanising of the modern counterpart of that "London 'prentice" immortalised in Scott's "Fortunes of Nigel." If, according to Lord Palmerston, "dirt is only good matter in the wrong place," the "teppista" may be regarded as good energy only misapplied, and, as the report of the Milanese "Croce Verde" shows us, may be brought to reinforce the army of order through discipline in the service of hygiene, physical and moral.

Winter on the Great St. Bernard.

The hospice still in requisition on this historic mountain has had to contend with exceptional difficulties during the past winter. Even 10 days ago (April 18th) a correspondent tells me that the ground adjacent to the hospice was still under four metres of snow—in some places as many as five metres. The quantity of the snow which has fallen from November to April as measured by the pluviometer amounted to nine metres on the Swiss side but to much less on the Italian. This severe weather notwithstanding, the number of wayfarers and working men who have sought and obtained shelter at the hospice has during the past six months been from 1200 to 1300, many of these cases demanding prompt and energetic restorative effort on the part of the monks. Thanks, however, to the experience, the skill, and the resources of these good men, no case of death occurred among those rescued or among the relief parties themselves. All the same, many of the "arrivals" at the hospice were found suffering from frost-bite of the hands and feet, principally in the month of lovers of the beautiful, but after some years of consideration it has now been decided that the present scheme is an absolute need for the well-being of Egypt and that the same benefits cannot be obtained in any other way. Sentiment must give way to practical utility and we must remain content with the knowledge that the antiquities of the island of Philæ, which owe their chief reputation not to archæological value but to the beauty of their picturesque surroundings, have been, at a cost of several thousand pounds, so consolidated by underpinning their foundations and carrying everywhere the masonry down to the solid rock that they are, though submerged, in a more stable condition than at any time of their past history and far safer even than the majority of the monuments in other parts of Egypt. It cannot, however, be suggested that the annual flood will have a beneficial effect upon their inscriptions except that it will wash away the deleterious salts which are ruining the stone work. Ample time is now afforded for the careful copying and recording of any inscriptions which may in future be inaccessible to the winter visitor to Egypt.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

McGill University: Medical Buildings Burned.

A FEW weeks ago the fine engineering building of McGill University, Montreal, was completely destroyed by fire. It had only been built some 13 years, and had been presented to the University by Sir William Macdonald, the millionaire tobacco manufacturer of that city. Now the ravages of fire have again visited the university, and this time the medical building has been destroyed. April 16th was the day of the conflagration. Amongst those who have suffered severe personal loss are Dr. F. J. Shepherd, Professor J. G. Adami, and Professor Ruttan. All of the first's anatomical materials are gone; Professor Adami has lost his valuable library which he kept in the building for the benefit of the students. At first it was thought that the manuscript of a new work on pathology, which he has been preparing for years, was also burnt but this has been saved. Many valuable pathological specimens, including the finest collection of calculi in America, have been destroyed, as well as the collection of brains made by Professor W. Osler when he was pathologist at the Montreal General Hospital. Professor Ruttan has also lost his library and all his chemical apparatus. The Medical Faculty of McGill University was the direct outcome of the old Montreal Medical Institution, which was organised as a medical school in 1823. In 1829 this Medical Institution was merged into the Medical Faculty of McGill University. The first university degree was a medical one and was conferred in 1833. During the Canadian Rebellion of 1836-39 there were no sessions held, which accounts for the fact that the present is the seventy-fifth session. In 1844 the number of students in the Medical Faculty was 50; in 1851, 64, with 15 graduates; in 1892-93, 315, with 46 graduates; in 1902 440 medical students were registered; and since that date the number annually has been about the same. In 1893 Lord Strathcona endowed the chairs of pathology and public health with $100,000. In 1899 Lord Strathcona again gave the Faculty $100,000 for extending and developing the laboratories, and a still further donation of $50,000 in 1904. The main building had been erected in 1873. In 1885 and again in 1893 large additions were made to it. It stood four storeys high except in the front block. Its total length was 290 feet and its width 145 feet. The belief is growing that the fire is of incendiary origin and an investigation is now proceeding.

Medical Inspection of Schools in Montreal.

Dr. J. E. Laberge, the health officer of Montreal, has prepared a report which shows that 20,000 school children are affected with divers ailments in that city. The report is the outcome of the system of medical inspection of schools which has been carried on in Montreal for the six months ending March 31st, when inspection was stopped owing to lack of funds to pay the medical men engaged in the work. The report shows that the inspection is urgently required, that 1400 children are suffering from inflammation of glands of the neck, that 1022 have defective eyesight, that 9478 have defective teeth, that 2453 have enlarged tonsils, and that 1572 had vermin. So far as infectious diseases were concerned, that part of the work which probably appeals to parents more than anything else, five cases of diphtheria were found attending school, four of scarlet fever, 26 of measles, 19 of whooping-cough, five of mumps, and five of chicken-pox. Then there were found of contagious skin diseases 46 cases of itch, 27 of impetigo, and 97 of ringworm; whilst 30 children had St. Vitus's dance, 104 had heart troubles, and 89 had lung troubles. The report is also interesting as regards the situation, ventilation, &c., of the schools. There were three schools with no ventilation at all. There were three situated in a basement, one in a garret, and three were found that only had their floors washed twice a year. One school had its floors washed once per annum, and yet another only once in two years. But in the face of all this Montreal has discontinued the medical inspection of schools.

Cremation in Montreal.

The secretary's report read at the third annual meeting of the Crematorium, Limited, which was held recently in Montreal, gives some interesting figures of the growth of cremation in that city. Outside Montreal cremation is not practised in any part of Canada. From the commencement of operations in 1904 to April 2nd, 1906, there had been 33 cremations, to which are to be added for the year ending Feb. 28th, 1907, 19. Including the cremations performed under the charter of the Mount Royal Cemetery Company prior to the establishment of the crematorium, which numbered 12, there have been all told 64 cremations in Canada. It is said that in comparison with other cities outside Canada where cremation is carried on it is progressing favourably in Montreal.

The Death of Dr. William Henry Drummond, Montreal.

By the death of Dr. W. H. Drummond Canada has lost one of her distinguished sons. Going to Cobalt, Ontario, the great silver mining centre of Canada, a few days before he died to investigate a reported epidemic of small-pox in his mining camp (his brother and he owned the Drummond Mine) he was stricken with paralysis, and although skilful friends in the medical profession in Montreal hurried away to his bedside he died on April 7th and was buried in Montreal. The late Dr. Drummond was a big, strong, athletic man, having been at one time champion three-mile runner of Canada, a good shot-putter, and an all-round athlete. He was born in Leitrim, Ireland, and was 52 years of age at his demise. A graduate of Bishop's College, Montreal, he rose to be professor of medical jurisprudence in his *alma mater*; he was at one time editor of the *Canada Medical Record*, now merged with the *Montreal Medical Journal*; but chiefly he became famous through his poems of French-Canadian farm-life, timbering, and boating. "The Habitant," "Johnny Corteau," "The Wreck of the *Julie Plante*," and "Old Dr. Fiset" will live in the history of this young country.

Toronto, April 19th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The "Thaw Murder Trial."

FOR 12 weeks this community has been intensely disturbed by the various phases which this noted trial has assumed. To the medical profession it has had an especial interest owing to the large number of experts in insanity who were called on either side to determine the mental condition of the prisoner, not only at the time of the murder on June 17th, 1906, but at the time of the trial. With the citizens at large the interest centred in the character of the murderer and his victim, the former being the son of a lady of great wealth, and the latter one of the foremost architects of the country. The murder was committed at a fashionable public resort in the midst of its festivities and was witnessed by hundreds. The only question at issue was the plea of the defence—insanity. That plea was based on (1) heredity; and (2) a revolting story of assault by the architect upon a girl-actress to whom the defendant proposed marriage, the story being related in all its filthy details in court precisely as she related it to the defendant as a reason for declining his offer. The defence endeavoured to prove by its medical experts, seven in number, less neglected cases had come under skilled treatment. Thus among the 47 fatal cases there were 16 patients who died within 48 hours after admission to the hospital. Among the 163 patients with laryngeal stenosis 67 were intubated, of whom 41 (62 per cent.) recovered and 26 (38 per cent.) died. As for the time of the intubated condition it averaged 74½ hours in patients suffering from pure laryngeal croup, while in diphtheritic croup it averaged 53½ hours. In one case, however, the tube was kept in the larynx for 348 hours. It is advisable to administer the serum freely and as soon as possible after the onset of the illness. Thus several times there were injected from 10,000 to 14,000 immunity units in the case of children of one or two years of age. 2. Faulty or doubtful diagnoses in connexion with acute infective diseases. The correct and rapid diagnosis of acute infective diseases is important not only from the point of view of recovery but also from the social hygienic standpoint, in order to render isolation and the carrying out of prophylactic measures possible. If, for instance, a patient is admitted to a hospital with an erroneous diagnosis of scarlet fever he or she is at once placed amid scarlatinal patients. It may happen, however, that at the physician's visit the patient is found to be suffering not from scarlet fever but from measles. It is clear that such a patient not only exposes the others to the risk of contracting measles but is also liable to be infected with scarlet fever. This circumstance induced Dr. Gerlóczy to provide observation wards for all cases of infective disease where the patient is kept for 24 hours and after being thoroughly examined is ultimately sent to the proper ward. The frequency of erroneous diagnoses is shown by the fact that during the last two years the following cases were sent in as scarlet fever: 43 cases of angina, 13 of rubeola, 11 of eczema, eight of gastric catarrh, six of measles, six of erythema multiforme, six of erythema toxicum, four of urticaria, four of sudamina, three of stomatitis ulcerosa, three of bronchitis, three of croupous pneumonia, one each of lymphadenitis colli, erysipelas, syphilis, influenza, and pleurisy, and 16 persons not suffering from any illness. The following cases were sent with a diagnosis of measles: 22 of rubeola, eight of urticaria, six of tonsillitis, four of erythema multiforme, three of dyspepsia, three of pityriasis rosea, two of syphilis, and one each of sudamina, scarlet fever, bronchitis, eczema, erythema nodosum, and conjunctivitis phlyctenulosa; one person in good health was also sent. Other mistakes in diagnosis occurred in connexion with cases of diphtheria, diphtheritic croup, pertussis, varicella, modified small-pox, rubeola, epidemic cerebro-spinal meningitis, dysentery, and typhoid fever.

April 27th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Gratuitous Treatment by Municipal Accoucheurs.

IT has been decided to appoint accoucheurs for each municipal district whose duty it will be to render gratuitous treatment to poor women in confinement. These accoucheurs will be chosen by the authorities of the medical faculty of the Haidar-Pasha School of Medicine. Care will be taken to select skilful men and a medical inspector will be appointed to see that they conscientiously fulfil their obligations.

Exanthematous Diseases.

All the schools in the suburb of Haskeuy on the left bank of the Golden Horn have been closed this week because of an outbreak of scarlet fever. The necessary measures for checking the epidemic have been taken, but several deaths from the disease have occurred.—From Smyrna I hear that small-pox is spreading in rather alarming proportions. Two causes account for this state of affairs. Firstly, the population, being ignorant of the advantages of vaccination, will not take their children to the public vaccinators; and, secondly, the latter themselves do not attach much importance to the vaccination laws and neglect their duties. The sanitary inspector of the vilayet of Smyrna has sent to Constantinople a memorandum urging the taking of immediate steps to enforce the vaccination laws throughout the whole province and the sending weekly of at least 300 tubes of calf lymph. It is intended to create a vaccination institute in Smyrna.

The Practices in the Slaughter-houses.

Up to now there has existed in the metropolis a practice of killing animals in the slaughter-houses by night, with the result that the municipal veterinary surgeons were not present and so the state of health of the animals was not ascertained. The Superior Council of Hygiene has issued an order approved by Réchid Pasha, the prefect of Constantinople, enjoining that in future all slaughtering of animals is to take place during the day only. Any contravention will be severely punished. The butchers will now, it is earnestly hoped, not be able to sell to the public the meat of diseased or tuberculous animals.

Notes.

Aidin is to be provided with canalisation works to enable the population of that town to have good drinkable water. The expenses will amount to 15,000 Turkish liras, which sum it is intended to raise by a surtax of 10 paras (a halfpenny) on each quintal of goods imported and exported.—Mme. Takvor Pasha, the sister of the late Dr. Khorassandjian, has offered 12,000 Turkish liras to the Armenian Hospital of Constantinople.

April 26th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

The Water-supply of Egypt.

Lord Cromer's annual report was dealt with recently in THE LANCET.[1] A postscript in the form of another Blue-book relates to the water-supply of Egypt. The huge dam at Assouan has been a profound success, and by holding up water in the winter months has enabled much new land in Lower Egypt to be brought under cultivation and has caused a considerable rise in the cotton crop, the value of which was estimated last year at £23,000,000. But the reservoir only supplies about one quarter of the water which is necessary for Egypt and the agriculturists have for a long time been demanding a further instalment. After mature deliberation the Egyptian Government has decided that none of the sites proposed for the building of the new dam is so suitable as the existing reservoir at the cataract of Assouan. It has therefore been decided to raise the existing dam some 23 feet at a cost of about £1,500,000. This is obviously a justifiable expense, for it will enable nearly 1,000,000 acres of land to be brought under cultivation and the value of the cotton crop alone in the area reclaimed will amount, it is calculated, to from £3,500,000 to £4,000,000. The work will take some five years and in the meantime the officials of the Irrigation Department will be able to decide what steps shall next be taken to store the waters of the Nile. Everyone agrees that it will be necessary, sooner or later, to prevent the present waste of water in the marshes south of Khartoum so as to insure an increased supply for the Soudan during the months of low Nile. It is still considered that it will be best in the future to devote the waters of the Blue Nile to the needs of the Soudan and those of the White Nile to the irrigation of Egypt. By raising the dam, as now decided, the storage of nearly two and a half times the present quantity of water in the reservoir becomes a simple engineering problem. It must be remembered that, although there is a modern water-supply for two or three of the largest towns, the rest of the inhabitants of Egypt drink water which is directly and daily drawn from the Nile or the canals which are its artificial tributaries. Everything, therefore, which is done to promote the volume of the water and the velocity of its flow helps to insure a purer drinking-supply during the time of low Nile. This is important during every summer, when diarrhœa and dysentery are liable to be prevalent, especially among children, and it becomes of the highest necessity on the occasions when the health of the community is menaced by cholera.

The Island of Philæ.

The disappearance of the island of Philæ, except between the months of July and October, is necessarily a grief to all a most interesting presentation portrait of Mr. Arthur Evans the archæologist (this is to be hung in the Ashmolean Museum). Of several portraits by Mr. J. J. Shannon that of Mrs. Tekelheimer will be most admired; Mr. George Henry adds to his laurels as a painter of beautiful women and has had great opportunities in his sitters; Mr. Christopher Williams sends a good likeness of Sir John Williams; Mr. Nowell is equally successful in a grave and quiet portrait of Herr Paul David, the well-known director of music at Uppingham School (a presentation portrait from old pupils); Mr. Harold Waite in a portrait of Mr. Justin McCarthy reproduces the almost painful facial contortions of presbyopia with fidelity, but sacrifices to that fidelity the grace of the picture; Mr. William Ranken's extremely clever portrait of Mrs. Brown Potter gives the well-known actress a *chevelure* of an almost impossibly daring red; Mr. Harris Brown's portrait of Sir Andrew Noble is a vigorous and thoughtful exploit; and Mr. Sargent continues to prove that he is the really great and original portrait painter of them all. Mr. Sargent is not so sensational or audacious as he has been on some occasions, but the easy mastery with which he paints, his psychological instinct, and his uncompromising candour are as well displayed as ever.

---

[1] THE LANCET, April 20th, 1907, p. 1103.

There is a notable absence of pictures telling any story or illustrating any episode of particularly medical interest. There are no sick-beds or ministering physicians and almost no nude anatomical studies. The natural colour of the healthy human being seems to be more widely recognised by the exhibitors this year, for the involuntary presentments of anæmia or jaundice, of which we have had formerly to complain, are practically absent. One painter, Mr. Sigismund Goetze, is determined to be in the van of the movement for stimulating the natural method of the feeding of infants. In a well-executed but banal allegory, entitled "Greatest of These," the central figure is a lady suckling a child of four, which is somewhat of a physiological exploit.

In the sculpture gallery there is an excellent bust by Mr. Hope Pinker of the late Sir John Burdon Sanderson.

ASYLUM REPORTS.

The Lancashire Inebriates Reformatory, Langho, near Blackburn (Third Annual Report of the Lancashire Inebriates Acts Board).—At the beginning of 1906 there were 120 persons under treatment in this institution. During the year 26 were received, seven were released on licence, one was transferred to Aylesbury State Reformatory, and 14 were discharged on expiry of sentence. Although there were many "mental defectives" none have been certified as insane during the year. Only three persons have been committed under Section 1 of the Inebriates Act, 1898. Under this section any habitual drunkard who is convicted on indictment of any offence punishable with imprisonment may be committed to a reformatory, provided that the court is satisfied from the evidence that the offence was committed under the influence of drink or that drunkenness was a contributing cause of the offence. Dr. F. A. Gill considers that neither the cost of detention to the committing authority nor lack of accommodation can be advanced as a reason for the little use made of this section. Probably the chief reason is the necessity for the indictment to higher courts—a proceeding which involves delay and extra work. Dr. Gill believes that more cases of attempted suicide might be treated under this section with good results. He states that larceny, violence to the person or property, and cruelty to children are amongst the most common crimes, and perhaps the most important of these from our point is the last. The mothers generally do well after release and the benefit to their husbands and their children is incalculable. Under Section 2 of the Inebriates Act, 1898, any habitual inebriate who commits any offence mentioned in the first schedule of the Act—e.g., being found drunk in a public place, drunk and disorderly, &c.—and who within 12 months preceding the date of commission of the offence has been convicted summarily at least three times of any of the offences so mentioned, may be sentenced to detention in a reformatory. Any person charged with an offence against this section may refuse to be dealt with summarily and may then be committed for trial on indictment. Fewer cases have been committed under this section than in the two preceding years. The inmates are chiefly employed in laundry work, needlework, wood-chopping, and farm work of all kinds. Before leaving the reformatory on the expiry of sentence every woman is offered assistance through the medium of one of the various societies which have kindly offered to help in the important work of after-care. Dr. Gill reports that with the help of the above and the police he has endeavoured to keep in touch with all cases released, and so far as he can ascertain their conduct is as follows: seven doing well, five cannot be traced, eight have relapsed, and one has been convicted of crime but not for drunkenness. With regard to the discharges, several of them throughout their sentence showed the utmost indifference to their future welfare and would probably make little or no effort to keep sober when discharged. Nine showed quite obvious symptoms of mental defect and two are chronic invalids as well. Their previous convictions recorded an average of 22·8 each. Dr. Gill states that regarding the eight discharges who relapsed, it is a pity that their sentences were only for two years, as another year might have made all the difference between a cure and a failure. In order to show the mental state of those who have been under care in the reformatory since it was opened in 1904 Dr. Gill has drawn up a table which is well worthy of consideration. He shows that 2·3 per cent. were insane, 7 6 per cent. were very defective, 50 per cent. were defective, and only 39·7 per cent. were of average mental capacity. Thus the proportion of mental defectives to the total committed to the reformatory is over 60 per cent. Dr. Gill gives the following as the mental characteristics of the habitual drunkard: (1) an absolute disregard for truth; (2) delusion of persecution; (3) a sense of rectitude; and (4) lack of self-control. The medical director concludes his report by discussing some of the various remedies for the treatment of the habitual drunkard. Repeated short terms of imprisonment he considers to be worse than useless, for in a very large proportion of the cases the individuals are mentally defective. This fact is clearly demonstrated in the report of the medical inspector under the Inebriates Act, 1898, for last year, in which he gives the percentage of mentally defective as over 62 per cent. Dr. Gill states that these figures show up the true psychology of the police-court habitual drunkard with startling vividness and should be seriously considered by all who are so ready to denounce reformatories for their apparent futility as curative institutions. He welcomes the newer treatment in reformatories as scientific, humane, and rational, for it is now possible to sift the material and thereby to give the hopeful ones a chance and to protect the more degenerate. A life of idleness is not advocated, for they ought to contribute something towards their maintenance and this is better done under supervision and discipline than as free agents. Dr. Gill considers that more might be done to prevent the manufacture of drunkards by segregating the older habitual drunkards and so withdrawing their evil influence and example from corrupting others. Mental defectives are not naturally drunkards but have acquired the evil habit as the result of environment, and the pernicious element of which is the association with other drinkers. This is shown by the fact that there are few or no cases committed to the reformatory from rural districts. Now rural districts have a proportion of mental defectives as well as towns, but they do not seem to be manufactured into inebriates as they are in towns, the chief factor in this being probably the absence of vicious environment and example. The only remedy for the majority of the feeble-minded class of habitual drunkard is permanent detention and as the law stands at present this is impossible.

EAST-END MOTHERS' LYING-IN HOME.—The report for 1906 shows that this charity continues to do excellent work; 430 women were delivered in the home and in the out-patient district 458 women were attended at their confinements. Of 833 children born alive 11 died. There were two deaths of mothers in the home and none in the district. The number of out-patients attended shows a decrease from the last report, which is attributed to the poorer women being unable to meet the fee of 2*s.* 6*d.* charged on each letter. At present the total number of beds in the home is 22 and it is desired to collect funds to increase this accommodation. The annual meeting of governors will take place on May 9th, at 4.30 P.M., at 17, Cavendish-square, London, W., by kind permission of the Earl and Countess of Bessborough.

that such a tale of cruelty inflicted upon the object of the defendant's love would so affect his unstable brain that years after he heard of the occurrence he would arm himself and deliberately kill the assailant, though the defendant himself travelled about Europe with this girl, living as man and wife, after learning of her downfall, and before they were lawfully married. While the defence aimed to prove insanity at the time of the murder it also aimed to prove that the defendant had meantime recovered and thus to prepare the way for his escaping both execution for his crime on the ground of insanity at the time the crime was committed and commitment to an asylum as a criminal afflicted with incurable insanity. The position was an exceedingly difficult one for a medical expert witness under cross-examination by an attorney as learned and resourceful as our prosecuting officer. They had abundant opportunities personally to examine the prisoner, a privilege denied to the half-dozen experts who appeared on the part of the prosecution. While the experts for the defence declared the prisoner insane when he committed the crime they refused to classify the form of insanity, but stated that he was subject to "brain storms," and the senior counsel of the defence invented the term "dementia Americana." The six experts on the part of the prosecution united in the opinion that the prisoner was suffering from paranoia and was incurable. This disagreement resulted in the appointment of a Commission in Lunacy, consisting of one physician and two lawyers, who were directed to determine whether the prisoner was insane at the time of the trial, and on its conclusion that he was sane at the time of their examination the case went to the jury, with the result that there was no agreement. This trial has proved exceedingly damaging to expert medical testimony. For three months 12 of the most prominent alienists of this country, divided into two camps of six each, have aided the attorneys of their respective sides, by private counsel and on the witness stand, in maintaining directly opposite opinions as to the mental condition of the prisoner. However honest and independent these alienists may have been in the formation of their opinions the public came to regard them as partisans, subsidised by enormous fees. To the lay mind, the adroitly evasive answers of the experts, their efforts at repartee with the attorneys, and their refusal to answer questions which would evidently impair the line of prosecution or defence, for which they were engaged, were satisfactory proofs that such testimony was not trustworthy. This public judgment of the untrustworthy character of medical expert testimony in the Thaw case strongly reinforces the growing prejudice in this country against medical expert testimony in all cases.

A New Defence in Cases of Railroad Injuries.

An interesting case was recently in the courts of the State of Texas. A woman, who was a "Christian Scientist," was injured in a railroad accident. She brought a suit against the company, alleging that she suffered severe pain as the result of the accident. The defence was that as she was a believer in "Christian Science," a religious faith which enables the believer to prevent pain in her person by the exercise of her will, her failure to employ her faith for her relief was contributory negligence. The lower court, in which the case was first tried, rejected this defence and the prosecution won a verdict for damages. On appeal the highest court of Texas reversed the decision of the first court and ordered a new trial on the ground that the plaintiff was in law bound to use proper measures for the relief of pain, and as she had implicit faith in "Christian Science," which taught that pain could be prevented by the exercise of the will of the sufferer, her failure to employ that remedy was negligence. It was required that in the re-trial the defence should be allowed to introduce evidence for the consideration of the jury relating to the plaintiff's faith in the "Christian Science" method of preventing and relieving pain.

Vaccination in the Philippines.

Dr. V. G. Heiser, chief United States quarantine officer of the Philippines, states that the systematic vaccination of the people has resulted in a very marked diminution of small-pox to a degree unknown for 300 years. During the quarter covered by the report the work of vaccinating the entire population of Cebu was completed, the first time in the history of the Philippines that the people of a province, numbering over three quarters of a million, have been vaccinated. Whenever the vaccination of a province is completed the work is followed up by vaccinating every six months all the children who have been born during that period and all unvaccinated persons who may have taken up their residence there during the interim.

Law controlling Marriage in the Interests of Public Health.

The Philadelphia County Medical Society recently passed a resolution expressing its approval of a Bill before the Pennsylvania legislature requiring certificates to the effect that both parties to a proposed marriage are, in the opinion of a qualified physician, free from disease transmissible to progeny. Similar measures are now before several State legislatures and in two or three instances they have been enacted into law and are now operative.

A New Name for the Mosquito which communicates Yellow Fever.

The Departments of Public Health and of Agriculture through the bureau of entomology, have adopted the name of "stegomyia calopus" as the name of the yellow fever mosquito. It has been known heretofore by several names, such as culex fasciatus, culex calopus, and stegomyia fasciata. More than a century ago the mosquito, now recognised as the species having the power of communicating yellow fever to the human subject, was classified as a culex, with the title of culex fasciatus, a name formerly given to an insect not identical with this one. The term culex calopus was adopted later, but with the classification of this mosquito with the genus stegomyia it is now proposed to give it the name, stegomyia calopus, by which it will hereafter be designated officially in this country.

April 19th.

THE ROYAL ACADEMY EXHIBITION.

THE one hundred and thirty-ninth exhibition of the Royal Academy of Arts will be opened to the public on Monday next, May 6th, and the public will find in the beautiful galleries of Burlington House a show of average merit—that is to say, there is provided for their inspection a few good pictures, a great many pleasing works, and a certain number of canvases for the presence of which it is not easy to account. The accusation repeatedly brought against the Academy that the wall space is largely monopolised by the Academicians and Associates is not in the least borne out this year. To treat the outsider generously came into fashion at the exhibitions of the Royal Academy some ten years ago, and appears now to have grown into a custom. The day when the line of sight was monopolised in room after room by large replicas of the bygone exploits of Academicians is over, a reform which makes distinctly for the popularity of the exhibition, while showing the Academicians and the Associates to distinct advantage as artists.

In landscape the present exhibition is strong; there are good examples of every sort and the best work is the work of the old hands. The most likely to arrest attention are the poetic pictures of Mr. Alfred East, the simple but admirably executed pictures of Mr. Leader, the examples of their art sent by Mr. Joseph Farquharson, Mr. Peter Graham, Mr. J. MacWhirter, and Mr. David Murray, and the sun-flooded canvasses of Mr. Clausen and Mr. La Thangue. We do not always find it easy to believe in Mr. Clausen's prismatic sun-effects, but if his daring betrays him sometimes it enables him at others to achieve wonderful success. Mr. La Thangue's work is far more obvious, but exhibits just as accurate observation of the wonderful manner in which a flood of light may transmute the soberest objects into lines and masses of gorgeous colour.

Portraits on the whole are not so numerous, we think, as they have been of recent years, or is it that the comparative absence of the robes and uniforms belonging to various mayoralties, doctorates, and services are less in evidence? There is a sound little representation of the King by Mr. A. S. Cope, and a good portrait of Sir William Perkin by the same artist, the subject's life-work being effectively if naively indicated by his grasp of a mauve ribband; the Hon. John Collier's portrait of the late Sir Michael Foster is a dignified picture and an admirable likeness; Mr. Albert Collings sends a portrait of Lord Ampthill, which depicts that excellent administrator as nine feet high; Sir William Richmond exhibits an alert and dignified portrait of Miss Mary Robinson and

London Hospital for Diseases of the Chest each receive £500. The ultimate residue of his estate is to be distributed amongst the Westminster, Guy's, and St. Mary's Hospitals, London, the General Hospital, Tunbridge Wells, and the Glasgow Royal Infirmary. The estate is valued at £119,508.

KING'S COLLEGE (UNIVERSITY OF LONDON).—The forty-seventh annual dinner of King's College, London, will be held at the Hotel Cecil on Monday, May 27th. The Bishop of St. Albans will be in the chair.

AMERICAN MEDICAL ASSOCIATION.—Mr. Herbert J. Paterson, F.R.C.S. Eng., is to give an address before the Surgical Section of the American Medical Association, which will meet at Atlantic City during the first week in June. The subject is, "The Operation of Gastro-jejunostomy and its Physiological Effects."

CROWNHILL CONVALESCENT HOME.—The annual meeting of the subscribers to the Crownhill Convalescent Home, near Plymouth, was held on April 25th. The medical report stated that during 1906 the in-patients numbered 279, compared with 317 in 1905. The financial statement was satisfactory and showed a favourable balance of £18.

PRESENTATION TO A MEDICAL PRACTITIONER.—At Treherbert, last week, the miners of the Fernhill, Blaenrhondda, and Bute Collieries, presented Mr. William Cathcart Hinde, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., with a clock, a set of cutlery, and an address as a mark of respect and esteem.

NATIONAL SANATORIUM, BENENDEN.—Princess Christian on April 30th formally inaugurated the completed portion of the National Sanatorium at Benenden, near Cranbrook, Kent, erected by the National Association for the Establishment and Maintenance of Sanatoria for Workers suffering from Tuberculosis. A description of the ceremony and the building will be published in a future issue of THE LANCET.

ROYAL DEVON AND EXETER HOSPITAL.—At the quarterly meeting of the governors of the Royal Devon and Exeter Hospital, held on April 25th, it was reported that there was an adverse balance against the institution of £1392, being £868 more than for the corresponding period of last year. The chairman (Sir Duckworth King) remarked that unless more support was forthcoming the committee would have to sell some more funded stock.

CERTIFICATES UNDER THE WORKMEN'S COMPENSATION ACT.—At a meeting of the Newbury and District Medical Society held on April 25th the following resolutions were proposed, seconded, and carried *nemine contradicente* and the honorary secretary was directed to forward a copy for publication to THE LANCET and the *British Medical Journal*, and also to every member of the society who was not present at the meeting.

Resolution 1.—That this meeting is of opinion that the certificates issued under the Workman's Compensation Act by any insurance company, which are required to be filled in at the expense of the injured workman and stating the probable duration of disablement, should not be signed by any member of this society.

Resolution 2.—That no certificate be filled up on behalf of the employer under the above Act for a less fee than one guinea.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Notification of Births Bill.

THE Bill to provide for the early notification of births, which Lord ROBERT CECIL has introduced into the House of Commons to deal with the problem of infantile mortality, has the support of Mr. LYTTELTON, Mr. SHACKLETON, Mr. VERNEY, Mr. GULLAND, Mr. MASTERMAN, Mr. SHERWELL, and Mr. TENNANT. It has been printed and the text of its operative clause is as follows:—

(1) In the case of every child born after the first day of January, 1908, it shall be the duty of the father of the child, if he is actually residing in the house where the birth takes place at the time of its occurrence, or in his absence of any person in attendance upon the mother at the time of the birth or within six hours thereafter, to send or give notice of the birth to the medical officer of the district in which the child is born within 48 hours after such birth.

(2) It shall be sufficient compliance with this section if notice be sent by prepaid letter or postcard addressed to the medical officer.

(3) It shall be the duty of all rural and urban sanitary authorities to bring the provisions of this Act to the attention of all medical practitioners and midwives practising in their district.

(4) Any person who fails to give or send notice of a birth in accordance with this section shall be guilty of an offence and shall be liable on summary conviction to a penalty not exceeding twenty shillings.

(5) The notification required to be made under this Act shall be in addition to and not in substitution for the requirements of any Act relating to the registration of births.

(6) This section shall apply to stillborn children as well as to children born alive.

Public Health Officers Bill.

Three members of the House of Commons, Mr. ARTHUR BLACK, Mr. HARMOOD-BANNER, and Mr. A. H. SCOTT, have given notice that they will move the rejection of the Public Health Officers Bill when the second reading of the measure is moved.

Opposed Bills.

The second reading of the Pharmacy Bill is to be opposed by Mr. BARKER and Mr. DUCKWORTH, whilst Mr. RADFORD has given notice that he will move the rejection of the Sale of Whisky Bill.

The Butter and Margarine Bill.

Sir EDWARD STRACHEY, who represents the Board of Agriculture in the House of Commons, has, as already stated in THE LANCET, moved the second reading of the Butter and Margarine Bill, which deals with the limit of moisture in butter and butter substitutes. Some of the Irish Members take exception to provisions in the Bill which will affect the Irish butter trade. Both Mr. WILLIAM REDMOND and Mr. JOYCE have given notice of an identical motion on this point, which will be moved as an amendment to the motion for the second reading before the debate terminates. It is in the following terms: "That, whilst it is highly desirable and necessary to legislate to secure proper regulations for the sale of butter, it is not expedient to interfere in any way with Irish salt firkin butter, for which there is a steady market and which is an important industry for large numbers of farmers in Ireland."

The Vaccination Bill.

Mr. JOHN BURNS on Tuesday presented a Bill to substitute a statutory declaration for the certificate required under Section 2 of the Vaccination Act, 1898, of conscientious objection. It was read a first time.

The text of Mr. BURNS's Vaccination Bill was issued on Wednesday. Its clauses are as follows:—

Clause 1.—The Vaccination Act, 1898, shall be read as if the following section were substituted for Section 2 of that Act:—

(1) No parent or other person shall be liable to any penalty under Section 29 or Section 31 of the Vaccination Act, 1867, if within four months from the birth of the child he makes a statutory declaration that he conscientiously believes that vaccination would be prejudicial to the health of the child and within seven days thereafter delivers the declaration to the vaccination officer of the district.

(2) A statutory declaration made for the purposes of this section shall be exempt from Stamp Duty.

(3) A statutory declaration for the purposes of this section shall be made in the form set out in the schedule to this Act, or in a form to the like effect.

Clause 2.—Section 2 of the Vaccination Act, 1898, is hereby repealed, but the repeal shall not effect the operation of any certificate obtained before the passing of this Act.

Clause 3.—(1) This Act shall come into operation on the first day of January nineteen hundred and eight.

(2) This Act may be cited as the Vaccination Act, 1907, and may be cited with the Vaccination Acts, 1867 to 1898.

The form of declaration required to be signed by the parent or person having the custody of a child, which is given in the schedule, sets forth that he shall "solemnly and sincerely declare that he conscientiously believes that vaccination would be prejudicial to the health of the child, and he makes this solemn declaration conscientiously believing the same to be true, and by virtue of the provisions of the Statutory Declarations Act, 1835."

HOUSE OF LORDS.

THURSDAY, APRIL 25TH.

Necrosis in Match Factories.

The Earl of LYTTON called attention to the death from necrosis recently reported from the factory of the Messrs. Moreland. He asked the noble lord representing the Home Office in the House whether, in view of the fact that phosphorus poisoning could not be prevented by the special regulations at present in force, His Majesty's Government would reconsider its attitude towards the Berne Convention prohibiting the use of yellow phosphorus in matches. The noble earl in putting the question mentioned that six European States—France, Germany, Italy, Holland, Denmark, and Switzerland—had signed the Berne Convention prohibiting the manufacture, importation, or use within their territories of matches made with the dangerous white or yellow phosphorus. Every kind of match which the public could require

Medical News.

University of Cambridge.—At a congregation on April 25th the following degrees were conferred:—

M.D.—G. S. Haynes, King's; J. G. Slade, Clare; L. Bousfield, Pembroke; and G. W. de Poulton Nicholson, Jesus.

M.B.—W. S. Tresawna, Sidney Sussex; and J. M. P. Grell, Selwyn Hostel.

B.C.—W. L. Murphy, St. John's; W. S. Tresawna, Sidney Sussex; and J. M. P. Grell, Selwyn Hostel.

Dr. L. Cobbett, late Professor of Pathology in the University of Sheffield, has been appointed a University Lecturer in Pathology as from Lady Day, 1907, to Michaelmas, 1911.—Mr. Cuthbert S. Wallace and Mr. Raymond Johnson have been appointed additional Examiners in Surgery for the M.B., B.C., and M.C. degrees.—Dr. Harmer, Mr. W. Bateson, and Mr. A. E. Shipley have been appointed delegates of the University to the Seventh International Zoological Congress, Boston, August, 1907.—Dr. E. Barclay-Smith has been appointed an Examiner in Human Anatomy for medical degrees, in the place of Professor A. Macalister who is abroad.—The following have passed both parts of the Sanitary Science Examination and are entitled to the University Diploma in Public Health:—E. J. Brown, J. B. Cook, C. Fraser, F. H. G. Hutchinson, D. C. Kirkhope, C. H. Lindsay, D. McKail, P. MacKessack, J. S. New, W. G. Parker, J. C. Robertson, J. B. Smith, A. N. Stevens, F. E. Stokes, and T. M. Strang.

University of Durham.—At the Third Examination for the degree of Bachelor in Medicine held in April the following candidates satisfied the examiners:—

Pathology, Medical Jurisprudence, Public Health, and Elementary Bacteriology.—First-class Honours; Eldred Curwen Braithwaite, College of Medicine, Newcastle-upon-Tyne. *Pass List;* Leonard Foster Browne and Charles Ernest Lewis Burman, College of Medicine, Newcastle-upon-Tyne; John Everidge, King's College, London; Reginald Cyril Herbert Francis, College of Medicine, Newcastle-upon-Tyne, and Guy's Hospital; Arthur Charles Greene and Hedvig Christina Kellgren, College of Medicine, Newcastle-upon-Tyne; Raghunath Vithal Khedkar, L.R.C.P. & S. Edin., L.F.P.S.G., Grant College, Bombay; Herbert Richard McAleenan and Friederike Rahtkens, College of Medicine, Newcastle-upon-Tyne; and Eric Frushard Waddington, University of Leeds.

Royal Colleges of Physicians and Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow.—In April the following candidates passed the undermentioned examinations:—

First Examination.—Five Years' Course: Tom Entwisle Ferguson, Bolton; Colin Hunter, Glasgow; Allan Ross Henry, Cape Colony; Hugh Francis Williams, Llanfyllin; Ishwar Das, Punjab, India; Patrick Walsh, Co. Limerick; John Scott, Dalry, Ayrshire; Charles Stuart Ogilvy, Blantyre; and William Woodburn M'Cowat, Transvaal.—*Four Years' Course:* Thomas Mitchell Jamieson, County Tyrone.

Second Examination.—Five Years' Course: David Lindsay Hutton, Glasgow (with distinction); Ernest Averell, Newcastle-on-Tyne; Robert Stobo Watt, Glasgow; Arthur Duncan Macarthur, Pollokshields; Robert Miller Danks, Coatbridge; Michael Vincent Walsh, Cork; Hugh M'Ilroy, Co. Antrim; and Robert Anderson, Delth.

Third Examination.—Abraham David Woolf, Birmingham; Henry William Turner, Glasgow; John McCall, Ulverston, Tasmania; James Thomas Gwynne Jones, Brecon, Wales; Abdul Mujid Shah, Patiala, India; Ernest Gibson, Cork; David Welsh, Lanarkshire; Ishwar Das, Punjab, India; Archibald Davidson, Melbourne; Maurice Edward Kayton, Bagdad; and George Noel Braham, Bath.

Final Examination and admitted Licentiates of the Three Coöperating Authorities.—Shridhar Chintaman Jog, Edinburgh; Joseph Hume Patterson, Glasgow; Oliver David Gunasekara, Colombo, Ceylon; Fred Garnet Allan, Whaley Bridge, Cheshire; Hugh Ferguson Watson, Gartnavel, Glasgow; Edward Robert Harriott, Jamaica; Arthur Annesley Stork Kats, Ceylon; Effie Jemima Cassels, Glasgow; Charlotte Eliza Pring, Bristol; Phiroza Behranji Mufabari, Bombay; Emile Hamel Smith, Edinburgh; Frederick James Breakell, Glasgow; Malcolm Ross Slack, Canada; Hugh Graham Anderson, Newlands, Glasgow; Ada Geraldine Boyletter Dias, Bombay; Hiralal Keshavlal Nanavati, Glasgow; Lennox Donald Napier, Egremont, Cheshire; and William Frederick Fismer Durr, Glasgow.

At the meeting of the Portishead (Somerset) urban district council held on April 26th Dr. Charles A. Wigan was elected chairman.

Medical Magistrates.—The names of Mr. William Wilfred Williams, L.S.A., and Mr. James William Stephens, L.R.C.P. Lond., M.R.C.S. Eng., have been added to the commission of the peace for the county of Pembroke.

Tiverton Infirmary.—The committee of the Tiverton (Devon) Infirmary has decided to enlarge the children's ward of the institution. Mr. J. Coles has presented a house adjoining the institution to be used as a nurses' home. He has also given £500 for the purpose of making necessary alterations which will be required in the building.

The Old Infirmary Site, Manchester.—As time goes on and the new infirmary in Oxford-road, Manchester, advances towards completion the destiny of the old site in Piccadilly becomes more interesting and the various views concerning it are expressed more warmly. Some would like every scrap of building removed and the whole area preserved as an open space. Others would keep the present buildings, adapting them, so far as possible, to serve as an art gallery and free library. Another small party would build about 250 shops on the ground floor of a building the upper part of which would serve for the art gallery and free library. These various schemes do not seem to have attracted any very large amount of public enthusiasm. The first is held to be only attainable at too great a cost. The present building is thought by many to be too heavy and dark readily to be made suitable for the display of works of art. The addition of 250 shops to those that already provide amply for the needs of Manchester is not looked for very eagerly by the shopkeepers of Market-street, King-street, Oldham-street, &c., who are struggling under heavy rents and heavy rates. It is said that there are not 250 shops in Market-street and King-street together, so that the addition of 250 more, for which there seems neither need nor room, would if successful swamp many old-established businesses, while if unsuccessful they would go far towards ruining this ambitious scheme. This question seems to have led to the formation of a new "Society of Friends of Art" in Manchester, which held a meeting on April 17th, at which Professor Boyd Dawkins moved a proposition approving the suggestion of the art gallery committee to widen their scope and to build an art gallery and free library on the infirmary site. The gallery would illustrate not only painting but various branches of art and would, in fact, be a museum as well as a picture gallery. There would be ample room for the building and a considerable open space round it. The motion was carried unanimously. On the whole the trend of opinion, so far as it can be ascertained, is in the direction of the last scheme.

Precautions against Plague in Calcutta.—The special health officer of Calcutta, Dr. T. Frederick Pearse, recently issued some simple precautions to the community against the spread of plague. The principal points to which attention is directed are: avoid sleeping on the bare ground at night, do not touch dead rats with the hands, avoid eating grain in which dead rats have been found, kill all rats and mice on premises, avoid the breath and discharges of plague patients, ventilate rooms well, and wash clothing and expose all clothes and bedding to sunshine regularly. The employers of labour and medical practitioners are enjoined to report persons suffering from ailments which in any way suggest plague infection.

French Medical Excursion to Central Europe.—A French medical excursion party (*voyage d'enseignement médical*), "Excursions Médicales Internationales, 1907," will visit several cities in Central Europe between August 7th and 23rd. The party will assemble at Nancy and will proceed to Stuttgart, Munich, Nuremberg, Carlsbad, Marienbad, Prague, Vienna, Budapest, Salzburg, Gastein, Innsbruck, Zürich, and Baden in Switzerland. The party will separate at Besançon-la-Mouillère. The programme and conditions of the excursion will be published at an early date. Inquiries, inclosing a postage stamp for reply, may be addressed to the *administrateur* of the society, M. Etienne Bazot, 8, Rue Françoise-Millet, Paris 16.

Donations and Bequests.—By the will of Mr. John Thomson of Tunbridge Wells the following hospitals each receive £1000: General Hospital, Tunbridge Wells, St. Bartholomew's, Guy's, London, King's College, St. George's, Charing Cross, Middlesex, University College, Brompton Cancer, St. Thomas's, Royal Free, Great Northern Central, and West London Hospitals, National Hospital for the Paralysed and Epileptic, Royal London Ophthalmic Hospital, Moorfields, Hospital for Consumption and Diseases of the Chest, Ventnor, Brompton Consumption Hospital, Hospital for Sick Children, Great Ormond-street, Victoria Hospital for Children, Chelsea, and Royal Hospital for Incurables, Putney. The Earlswood Asylum for Idiots and the City of epidemic of typhoid fever broke out at the asylum owing to the alleged defective sewerage, by which several of the patients lost their lives, and that the sanction of the Board of Trade became necessary owing to the fact that the sewers were to be carried over a small stream subject to tidal influence that ran dry in the summer season and that the principal owner and occupier of the adjacent lands gave his sanction to the project months ago.—Mr LLOYD GEORGE (in a written answer) replied The first communication in this matter from the Dublin Office of Lunatic Asylums was received in August last, but it was not until October that the necessary plans were forwarded to the Board, who, in the same month gave instructions for the application to be advertised The Lunatic Asylums Office, however, demurred to the newspapers prescribed by the Board for the advertisement, with the result that proofs of the advertisement were only received on Jan 5th last On receipt of these proofs the owners of the property adjacent to the site of the proposed works were at once consulted by the Board of Trade but one of them, though written to more than once, neglected to reply, thus causing delay The Board of Trade has now informed the inspectors of Lunatic Asylums that they are prepared to consent to the works on certain conditions. I have no information as to the matter referred to in the last part of the question.

Dispensary Doctors in Ireland.

Answering Mr. THOMAS O DONNELL, who asked a series of questions bearing on the amounts paid to dispensary doctors in Ireland, Mr BIRRELL wrote: The total amount of the salaries of dispensary medical officers in the year 1897 came to £90,727, of which one-half was recouped from the Parliamentary Grant. It would not be possible to state with accuracy the actual credit given to each county in respect of the salaries of dispensary medical officers In the year ended March, 1906 the salaries of medical officers, together with the payments for services of temporary medical officers, came to £110,134 of which it may be taken that somewhat less than one-half was recouped from the Local Taxation Account The exact amount of recoupment cannot be given owing to the limitation imposed by section 6 (1) of the Local Government Act of 1902. The salaries of medical officers are paid according to unions, and the unions are not in all cases coterminous with the counties The present number of unions extending beyond county limits is 46, but there were more than this number in 1897, and no sectional valuations are available for the purpose in that year, so that a comparative statement could not be arrived at.

THURSDAY, APRIL 25TH.

The Irish University Scheme.

Answering Viscount TURNOUR,

Mr BIRRELL said that he had received protests against proceeding with the Irish University scheme upon the lines laid down by the late Chief Secretary to the Lord Lieutenant for Ireland from the Senate of the University of Dublin, resident members of the University of Oxford principals and professors of the Scottish universities, of the University of Sheffield, the constituent colleges of the University of Wales, and of St. David's College, Lampeter, and from lecturers in the School of Medicine of the Royal Colleges, Edinburgh. So far as English and Scottish university opinion was expressed in these protests it was mainly confined to that part of the proposal which related to a federated university

Pulmonary Tuberculosis in Belfast Mills

Mr DEVLIN asked the Secretary of State for the Home Department whether his attention had been called to the high death rate in Belfast from pulmonary consumption and to the fact that the death rate was highest among mill and factory workers, the vast majority of whom were females; whether there was any female factory inspector in Belfast and, if not whether in view of the number of women and young girls employed in mills and factories in Belfast, he would consider the advisability of appointing a female inspector for that city and the North of Ireland generally Mr. GLADSTONE answered: The figures given in the report of the Registrar-General for Ireland for the year 1905 do not appear to me to show any necessary connexion between the deaths in Belfast from tuberculous disease and employment in the linen factories I may point out that the conditions obtaining in the flax and linen mills have been made the subject of a special inquiry by Sir Hamilton Freer Smith and that as a result new regulations for the industry have just been established dealing with the removal of dust, wet, &c., which should do much to improve the health of the workers I shall be glad to send the honourable Member a copy With regard to the last part of the question one of the lady inspectors resides in Belfast for two-thirds of each year, devoting her time chiefly to inspection in the city. Others of the lady inspectors also visit Ireland occasionally

Lead Poisoning in Royal Dockyards

Mr BRAMSDON asked the Secretary to the Admiralty to state how many cases of lead poisoning had been treated by the surgeons of Portsmouth, Devonport Chatham, Sheerness, and Pembroke dockyards respectively during the year 1906—Mr EDMUND ROBERTSON replied (by written answer) The following is the number of cases of lead poisoning treated during the year 1906 —Portsmouth 7 Devonport, 3, Keyham 2, Chatham, 2, Sheerness, *nil* and Pembroke, 2.

Cerebro-spinal Fever and Old Clothes

Mr SLOAN asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to a resolution passed by the Downpatrick rural district council against Belfast dealers displaying goods for sale on fair days in that town on the pretence that it was done to avoid the spread of spotted fever, and whether, in view of the fact that the Downpatrick council gave no evidence to support its contention and the fact that dealers from Belfast had been injured in their business he would call upon the council to justify its resolution or withdraw it —Mr BIRRELL furnished the following written reply: The Downpatrick town commissioners passed a resolution requesting the Downpatrick rural district council to take steps to prevent old clothes from being brought for sale into the town The district council thereupon inquired from the Local Government Board whether it had power to comply with the request and was informed in reply that the Board was not aware of any enactment giving such power except in the case of infected articles I have no authority to do what the honourable Member suggests.

Pauper Children

In answer to Mr W E. B. PRIESTLEY, Mr JOHN BURNS wrote: On Jan 1st, 1907, the numbers of pauper children relieved in workhouse infirmaries in England and Wales were as follows:—

—	Number of children chargeable to Poor-law unions in London.	Number of children chargeable to Poor-law unions outside London.	Total.
(*a*) Not including insane and idiots—			
(1) In workhouses, otherwise than in infirm wards ..	1,045	13,630	14,675
(2) In infirm wards or infirmaries ...	2,045	4,645	6,690
(*b*) Insane and idiots in workhouses*	14	302	316
	3,105	18,577	21,682

* There were also 132 children chargeable to London unions in district sick asylums and 797 children in the imbecile asylums belonging to the managers of the Metropolitan Asylum District.

The number of children over three years of age chargeable to Poor-law unions in London in the workhouses on Jan. 5th last was 446 and in infirmaries 1004 Similar information with regard to the rest of England and Wales is not available

MONDAY, APRIL 29TH.

The Royal Commission on the Feeble minded.

In answer to Lord ROBERT CECIL. Sir HENRY CAMPBELL-BANNERMAN said: I am informed by the chairman of the Royal Commission on the Care and Control of the Feeble-minded that the evidence has just been closed and that the report will be presented at the earliest possible moment, but how soon this would be it was impossible to say.

The Royal College of Physicians of London and the Plague.

Dr RUTHERFORD asked the Secretary of State for India what action had been taken by the Government in regard to a deputation of the Royal College of Physicians in May, 1905, to the Secretary of State for India pointing out the danger of the plague and recommending certain measures to be taken, and whether he would lay upon the table the memorandum of the College of Physicians.—Mr. MORLEY furnished the following written answer: Some delay which I regret has occurred in this matter. The memorandum reached India at a time when the Government of India had called for and were awaiting reports by the local governments on the subject of plague remedies, based on the personal experience of their officers These reports, which were very voluminous, were dealt with in a published resolution by the Government of India of Jan 17th, 1906 laying down in detail a complete policy for dealing with plague. This policy in its preventive features is in practical accordance with the memorandum of the Royal College of Physicians. The Government of India have since considered, in communication with the local governments, the recommendations of the memorandum for a special medical organisation for dealing with plague Their scheme has not yet been definitely formulated, but I understand that the sanitary service will be strengthened by employing a larger number of qualified natives of India. I shall be happy to lay the memorandum on the table if my honourable friend will move for it.

The Vaccination Order.

Mr LUPTON asked the President of the Local Government Board whether he would state the reasons for delay in issuing the Vaccination Order which on Feb 14th he stated in the House was to be circulated in a few days, and whether he would name a day by which the Order in question might be expected to appear —Mr BURNS replied (by a written answer) Some questions of difficulty have arisen in settling the details of the Order which have delayed its issue These will, I hope, be very shortly surmounted and the Order will then be issued

TUESDAY, APRIL 30TH.

Calico and Blood Poisoning.

Mr SUMMERBELL asked the Secretary of State for the Home Department whether he was yet in a position to report the results of his investigations in regard to the death of Ann Wilson at Sunderland through blood poisoning, alleged to have been set up through the dressing used by manufacturers in the making of calico —Mr GLADSTONE answered: I obtained a piece of the calico and had it subjected to analysis by an expert, who after various experiments reported that it was free from pathogenic organisms the organisms found being common contaminations of any material which is exposed to air.

Small pox in Germany

Mr LUPTON asked the President of the Local Government Board whether, in view of the epidemic of small pox in Germany and the probable derivation of vaccine from variolous matter in that country, he would take steps to prohibit the importation of vaccine from the continent into England during such time as the epidemic may continue.—Mr JOHN BURNS said in reply: I have no information as to there being an epidemic of small pox in Germany, although I am aware that there has been some prevalence of the disease on the frontier at Metz I have no authority to prohibit the importation of lymph from the continent, and I may add that I understand that any vaccine of variolous origin which is current in Germany and which is liable to be imported into this country would have been frequently passed through the calf.

Public Health Inspection in Scotland.

Mr WATT asked the Secretary for Scotland whether he would grant a return of the number of local authorities who had, and of those who had not appointed veterinary surgeons to carry out the provisions contained in sections 43 and 60 of the Public Health (Scotland) Act, 1897, and in Article 3 of the Dairies, Cowsheds, and Milkshops' Order of 1893 —Mr. SINCLAIR replied: I am informed that all the could be made without the use of this dangerous kind of phosphorus. The British Government, although it claimed to have the interests of the industrial classes at heart, would not join the other nations in their efforts to stamp out necrosis. However, it said that it would only join in the Convention on condition that every nation which imported matches did the same. The special regulations of the Home Office on this subject were not a sufficient protection. Since they came into force five cases of phosphorus poisoning had occurred in this country.

Earl BEAUCHAMP, on behalf of the Home Office, said that in 1900, when there was a good deal of discussion upon the question of phosphorus poisoning, the Secretary of State for the Home Department, instead of prohibiting the use of phosphorus in this country, caused special rules to be made and the memoranda which had been laid before Parliament showed that these rules had had very satisfactory results. There had only been five cases of necrosis in the five years during which these special rules had been in force. Three of these cases had been mild and the persons affected had recovered and were able to find other employment. The other two cases were fatal. As regarded the case to which the noble earl specifically referred to, it was probable that the disease was contracted before the special rules were made, because he was informed that necrosis lurked in the the body for a considerable period before making its appearance. The man had worked in a match factory for 12 years and it was very probable that he had caught the disease, which was of an insidious character, before the new rules came into operation. It would not be fair, therefore, to regard the case as being in any way due to a defect in these rules. The Government was of opinion that the special rules had been successful and it proposed to adhere to the position. The Home Secretary, however, had in contemplation amendments which were specially designed to meet such a case as the noble earl had brought to the notice of their lordships. Special arrangements would have to be made in regard to dental examination and the Home Secretary proposed to frame a rule to prohibit tobacco chewing, which was said by doctors to have a bad effect upon persons who worked in match factories.

MONDAY, APRIL 29TH.

Prohibition of Medical Practice by Companies Bill.

Lord HYLTON moved the second reading of the Prohibition of Medical Practice by Companies Bill. He said that he hoped to be able to convince their lordships of the necessity for legislation of the character proposed in the Bill. He would remind them that the Medical Acts of 1858 to 1886 provided in effect that only persons who were legally qualified by having passed prescribed qualifying examinations and by being registered in the Medical Register could lawfully practise medicine, surgery, and midwifery throughout the United Kingdom. It had been, unfortunately, true that what was illegal for one man to do himself as a physician or surgeon, it was legal for him to do if he joined unto himself five or six or seven other unqualified persons. It seemed a scandalous state of things that such should be possible; but unfortunately the General Medical Council, who were the body whose duty it was under the Privy Council to administer these Acts, had found themselves unable to stop these practices, and, in fact, they were widely spread. From a document furnished to him by the General Medical Council it appeared that the incorporation of these bogus medical and dental companies went on steadily and a good many of them had been registered since the matter was last brought before Parliament. He found that a circular had been widely distributed by a firm of company registration agents in which it was urged that unqualified men who wanted to act as doctors and dentists should avail themselves of the incorporation of companies as a means by which the prohibition imposed by the Medical Acts might be entirely avoided, this prohibition being described by them as onerous. He had been furnished by the General Medical Council with a long list of these bogus companies, and many of them were not included in the return to the House of Commons moved by Sir John Tuke. Some of these bogus companies had done great evil and the great object of the Bill was to protect the poorer classes of the community who were deceived by these sham companies. If these companies could be dealt with by the law and could be prosecuted it would be found that they would at once go into liquidation. The examination of the list of shareholders of the sham companies at Somerset House had revealed the fact that there were very few shareholders indeed, and only sufficient shareholders were taken into the companies to permit of them being formed. Their lordships might wonder why legislation had not taken place to protect the public and to prevent lives being sacrificed by these companies. The General Medical Council were not to blame in this matter. They had endeavoured to induce successive Governments to take up this matter and to initiate legislation. In 1900 Lord Halsbury put two clauses into his Companies Bill of that year and these would effectually have put a stop to these evils. These clauses were accepted by their Lordships' House. The Bill then went down to the House of Commons. Unfortunately for the views of the General Medical Council and others who took an interest in the matter, the clauses were struck out for the reason that they were not germane to a Companies Bill. He did not speak with any authority on that point, but the representatives of the medical profession in the House of Commons without exception, such as Sir Walter Foster and Sir John Tuke, and other Members, such as Mr. Bryce, begged the Government of the day not to take these clauses out of the Companies Bill. However, the month was August. Both Houses of Parliament were, as they usually were at that season of the year, anxious to get business through, and in order to prevent any opposition taking place to the Companies Bill the two clauses were struck out of it and in this condition it was passed. The general view of the medical profession was that something should be done to deal with this evil of practice by bogus companies. Since the Act of 1900 the General Medical Council had not been idle in this matter, but they had been unable to induce any of the Governments to take it up. Now, after H.M. Government had been approached it was suggested that a private Member like himself should bring in this Bill.

The Earl of HALSBURY supported the Bill. His lordship, who was indistinctly heard, was understood to say that the clauses dealing with medical companies had not been persisted in in the Bill of 1900, because with them it would have been hopeless to have attempted to pass the Bill. He had received an enormous amount of literature from the medical profession which showed that the law had been deliberately evaded by people turning themselves into a company. This was a very facile means of evading what the legislature had deliberately laid down with regard to the qualifications of medical men.

The Earl of CREWE, who spoke on behalf of the Government, said that the two noble lords had given the past history of this matter, which was by no means unimportant matter. He thought that what happened in 1899 was that the noble earl began by introducing a Bill dealing with this subject only, and then it was thought better to attempt to incorporate the substance of that Bill in the Companies Bill of the following year. When the two clauses in that Bill dealing with medical companies went to the House of Commons they met with the fate that had been described. He believed as a matter of fact that it was the friends of the noble earl himself who got them struck out. It was satisfactory that Lord Hylton had brought the subject before their lordships. His Bill in the opinion of the Government met something which nearly approached a public scandal—namely, the possibility of the evasion by unqualified persons of the law relating to medical practice. It was important to point out that in one respect the Bill contained a drastic provision. Not only did it interfere with the proceedings of unqualified people, but it also prevented the formation of a company which would employ fully qualified doctors to act for them. That was a strong decision. However, he thought that it was possible to justify it when they remembered that the relations of doctor and patient were so confidential that the weight of them ought to rest upon each doctor individually and he ought not to be able to shelter himself behind the name of a company. He further thought that it would be generally agreed that the kind of man who would be employed by a company would be one of the derelicts of his profession and it would be as well not to encourage the kind of practice which would take place if such companies were allowed to be formed. He understood that Lord Hylton was quite willing that this Bill should be referred to a Select Committee. If that course were followed the Government would fully concur in it. It was no doubt important that they should seek to avoid all hardship to individuals, and they desired to avoid any suspicion that they were dealing hardly with the kind of practice which obtained amongst the very poor. It was desirable that the matter should be thoroughly threshed out before a Select Committee. He hoped therefore that their lordships would agree to the second reading and allow this course to be followed.

The motion for the second reading was then agreed to.

Lord HYLTON then moved that the Bill should be sent to a Select Committee

This course was also agreed to.

Dental Companies (Restriction of Practice) Bill.

Lord HYLTON then moved the second reading of the Dental Companies (Restriction of Practice) Bill. He said that this Bill was almost on all fours with the preceding Bill dealing with medical practice. He did not know whether it was proper to deal with both subjects in one Bill or in two. The General Medical Council thought, however, that two Bills should be brought in There was a difference in the two Bills. This Bill did not propose to make it illegal for a company to practise dentistry provided that its members were registered dentists.

The Earl of CREWE said that this Bill was complementary to the other with the addition mentioned by the noble lord. He thought that this case was different from the one of the doctor. The dentist remained in his own torture chamber and generally did not visit the domestic circle of his patient. This provision did not apply to the doctor.

The Bill was then read a second time and was referred to the same Select Committee as should deal with the Prohibition of Medical Practice by Companies Bill.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 24TH.

The Ballina Dispensary.

Mr LONSDALE asked the Chief Secretary to the Lord Lieutenant of Ireland what action had been taken by the Local Government Board in regard to the appointment of Dr. Clarke as temporary medical officer to the local dispensary district, having regard to the fact that the Ballina board of guardians made it a condition of his appointment that he should use his influence to induce his uncle to relinquish his tenancy on the Orannagh farm.—Mr. BIRRELL replied: The Local Government Board has sanctioned Dr. Clarke's appointment as temporary medical officer of the Ballina dispensary district. No facts came to the knowledge of the Board which would justify it in withholding its sanction.

Medicine for the Edenderry Union.

Mr. LONSDALE asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that when advertising for tenders for the supply of medicines and surgical appliances the guardians of the Edenderry Union stipulated that the envelopes should be marked on the outside from Irish firms; that out of many tenders sent in only four were marked as directed, and only those four were opened and considered; whether this device was resorted to because the guardians had been warned by the Local Government Board that recoupment would not be made in any case where the guardians did not accept the lowest tender received by them; and whether, having regard to the fact that the practice of the Edenderry guardians was being recommended for adoption by other boards with the avowed object of boycotting English firms the Local Government Board proposed taking any action in the matter.—Mr. BIRRELL replied: The facts are correctly stated in the first two parts of the question. The regulations provide that recoupment from the Local Taxation Account will not be allowed in any case in which the guardians accept a tender other than the lowest without the approval of the Local Government Board. The Board does not consider that the contracts in this case have been entered into in accordance with the regulations and it intends, therefore, to disallow recoupment to the guardians in respect of the cost of any medicines or appliances obtained under such contracts.

Typhoid Fever in Clare Lunatic Asylum.

Mr. HALPIN asked the President of the Board of Trade whether he would inquire into the cause of delay in not returning plans of sewerage from the Clare lunatic asylum to the inspectors of lunatics in order that the sanction of the Lord Lieutenant should be obtained to carry out the works, those plans having been forwarded to the Board of Trade eight months ago; and whether he was aware that a serious

Notes, Short Comments, and Answers to Correspondents.

QUOTATIONS FROM THE LANCET.

WE are constantly having to protest against the way in which the proprietors of certain preparations misuse statements which have appeared in these columns. One of the worst offenders is the Vitæ Ore Company, Limited. Some years ago—namely, on March 25th, 1898—we analysed a sample of Vitæ Ore and mentioned that it contained 13·20 per cent. of ferric and 3·9 of ferrous sulphate. We ended our notice by saying, "The clinical results obtained were satisfactory, but the preparation showed no superiority over Bland's pills or other remedies used in the treatment of anæmia." The Vitæ Ore Company took this paragraph and extracted from it the six words, "The clinical results obtained were satisfactory," and these words they are constantly quoting in advertisements of the most blatant kind. A correspondent who is a Baptist minister has forwarded to us an advertisement from the *Baptist Times* in which the Vitæ Ore Company states that its preparation is "the most wonderful discovery of modern times for the successful treatment of ailments caused by a weak or diseased condition of the Stomach, Liver, Kidneys, or Blood, such as anæmia, rheumatism, dyspepsia, eczema, stone, hæmorrhage, wounds, sore-throat, tonsillitis, brain fag, &c." The six words above mentioned are quoted from us. We have no hesitation in saying that this quotation is a gross instance of misquotation. It implies that we recommended Vitæ Ore for the various diseases mentioned in the advertisement, a distinctly misleading implication. We have had upon a previous occasion—namely, in THE LANCET of Jan. 15th, 1905—to point out the misuse made of this quotation. We now charge the Vitæ Ore Company with deliberately using a portion of our statement with intent to deceive the public.

MEDICAL FEES.

To the Editors of THE LANCET.

SIRS,—In a recent article in the *Semaine Médicale* a passage is quoted from the work of Dr. Charles Floquet, "Code Pratique des Honoraires Médicaux," to the effect that it is the custom in England for a medical man to receive on his first visit twice the amount of his fee. On subsequent visits a single fee only is paid and when the patient wishes to signify that the doctor need not return he simply omits to pay and so the attendance comes to an end. As this *cliché* seems to recur every time that an article is written in a French medical periodical on the question of fees in foreign countries and is evidently an article of faith, you would render a service by publishing this letter together with your answer stating what truth there is in this legend and which would, no doubt, be reproduced by the French medical papers.

I am, Sirs, yours faithfully,
April 27th, 1907. FOLK LORE.

*** It is very usual for a "consultant" to charge £2 2*s.* for the first visit and £1 1*s.* for subsequent visits within a reasonable time. The two guineas, however, is the usual fee and not "twice the amount." The statement as to the method of signifying a desire that the attendance should end is, of course, nonsense.—ED. L.

WORKHOUSE MEDICAL OFFICERS AND THEIR DUTIES.

A CORRESPONDENT who applied for particulars of the appointment of assistant medical officer at the Swansea Union Workhouse received a paper setting out the duties of the assistant medical officer and a notice of the vacancy. From this we learn that *the assistant medical* officer must be resident and that as no accommodation for residence is at present provided he shall reside within 250 yards of the workhouse and be paid £30 per annum *for, we presume*, lodging money. His salary is £120 per annum, to include fees for certifying lunatics, extra medical fees, and fees for lectures. He shall also be appointed public vaccinator for the workhouse at the minimum fees. The duties are by no means light. Amongst others he is to accompany the medical officer in his visits to the patients and to carry out all the orders which he may give. He is to examine all children in the workhouse every other day or oftener if required. He is to observe that the nurses and attendants are attentive to their duties and to report them if necessary. He is to give weekly lectures to the nurses, to keep the infirmary medical records, to write out special reports of cases when required to do so to examine all wards of the infirmary twice every day, and to perform any other duties in the infirmary that may be required of him by the medical officer. If he leaves the workhouse or his residence for more than three hours he must inform the master. He must attend every workhouse visiting committee and must provide at his own expense a qualified practitioner to act as substitute during his absence from the institution, except during his annual holiday of two weeks when the guardians pay for his substitute. There are many other duties, and it seems to us that such heavy and responsible duties are not sufficiently remunerated by a salary of £120 a year in the case of a member of a liberal profession. The comfort of the post would of course largely depend upon the character of the medical officer and the master of the workhouse, to both of whom the assistant medical officer appears to be practically subordinate.

THE SPREAD OF INFECTION.

ON April 24th a man named William Lloyd of Lisbon-street Dwellings, Bethnal Green, was summoned by the Bethnal Green Borough Council at Old-street for failure to give notice to the sanitary authority that one of his children was suffering from scarlet fever. The evidence showed that Lloyd's wife took her two-year-old child to Mr. Snell of Bethnal Green who told her that the little patient was suffering from scarlet fever and diphtheria. The woman gave a false address and on the sanitary authority being notified the case could not be traced at first. Some days later, however, the parents were traced and the child was found very ill in a room used by other children. Mrs. Lloyd admitted that two of her children went from home every day to Somerford street public school, while two other girls, aged 18 years and 16 years respectively, went to work in a factory. The husband refused to have the child removed to hospital and said that if it had to go he would carry it through the streets himself. He could only be prevented from doing this by being told that he would be liable for exposing the child. He was fined 40*s.* and 2*s.* costs, but he chose to go to prison in default. This case shows very well the difficulty which the sanitary authorities have among a certain class of people in dealing with infectious disease. Mr. Margetts, who appeared for the borough council, said that poor people thought it was an indignity for the ambulance to call at their house and we fear that this is very often the case. Anything connected with municipal or parish relief other than hard cash is anathema to the poor and their very ignorance prevents them from seeing that to behave in the manner in which Mr. and Mrs. Lloyd did on this occasion is a danger not only to themselves but to their neighbours.

LONDON MEDICAL UNION.

To the Editors of THE LANCET.

SIRS,—It may be of interest to your readers to learn how the above society proposes to solve an ethical dispute between certain of its members. At a meeting of the council of the union the following resolution was passed after considerable discussion:—

"That in the case of a surgeon to a club or other similar body being asked to give an opinion to the club or other body about a patient known to be under treatment by another practitioner, the surgeon should insist on inspecting the certificate given by the medical attendant, and if not able to endorse it he should privately communicate with the medical attendant before giving an opinion."

I am, Sirs, yours faithfully,
A. F. SHOYER,
April 30th, 1907. Hon. Sec., London Medical Union.

CHILDREN'S SIGHT AND SPECTACLES.

IN THE LANCET of April 13th we commented on a letter from an optician named Dunscombe which had appeared in the *Western Daily Press*. Mr. Dunscombe now asks us to publish the whole of his letter and we do so.

BRISTOL EYE HOSPITAL.

SIR,—There is in the report of the excellent work done by the Bristol Eye Hospital, submitted to the subscribers at the annual meeting yesterday, a paragraph laying great stress upon the large amount of time spent by the Eye Hospital staff in testing the sight of school children, of which the committee would like to see the staff relieved, to enable them to deal more particularly with cases of disease in the eyes and with operations. This expression of opinion by such an authority is of great public importance, as showing the real work for which the institution is established. *None of the work* complained of need go to the Hospital; it is the work of the optician, and Bristol has qualified opticians capable of testing and correcting defects of vision, who would send all cases of disease and abnormality to the Hospital, or an oculist, *according to the circumstances* of the person, and thus enable the institution to fulfil its functions with even greater efficiency than at present.

Yours truly,
March 29th, 1907. M. W. DUNSCOMBE.

We still do not consider Mr. Dunscombe or any other optician as capable of diagnosing diseases of the eye.

THE METROPOLITAN WATER BOARD AND ITS PROPOSED MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—I inclose a letter I have received from the Metropolitan Water Board upon which, as a matter of interest to medical men, I should like to have your opinion. Is it possible that a public body expects a medical man to examine properly one of their employees and give a certificate, presumably in confirmation or otherwise of the employee's own medical attendant's opinion, and perhaps have to travel two or three miles to do this, for half-a-crown? Personally I have declined it on the ground that I could not do justice to the Board upon such terms. Considering that there is no question of charity here surely this is worse than the half-guinea for an examination for life insurance, of which we rightly complain as being so grossly unfair.

I am, Sirs, yours faithfully,
April 15th, 1907. M.B. LONDON.

*** The letter in question states that the Board proposed to appoint of a total number of 107 county authorities have approved the employment of veterinary surgeons for the purpose of Section 43 of the Public Health Scotland Act, 1897.

The Medical Officer to the Tokio Embassy.

Sir WILLIAM COLLINS asked the Secretary of State for Foreign Affairs whether an appointment to the medical officership to the British Embassy at Tokio was made in the early part of this year; if so, whether the vacancy was advertised; whether the gentleman appointed was a *British subject*; and, if not, whether he held any medical qualification recognised as registrable by the General Medical Council.—*Sir* EDWARD GREY *(by written answer) replied: There* was no vacancy. The medical adviser to His Majesty's Embassy proceeded on leave and made *arrangements for a competent substitute to act* during his absence.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.*

BERTRAM-HILL, W., M.B. Manch., has been appointed House Surgeon at the Hospital for Women and Children, Leeds.

FINZI, NEVILLE S., M.B. Lond., M.R.C.S., L.R.C.P., L.S.A., has been appointed Medical Officer in Charge of the Electrical Department, Metropolitan Hospital, N.E.

FISHER, H. R., M.B. Cantab., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Fillongley District of the county of Warwick.

GRIMBLY, RICHARD HENRY, M.R.C.S., L.S.A., has been appointed Medical Officer for the Ippledon District by the Newton Abbot (Devon) Board of Guardians.

HARMER, JOHN D., M.B., Ch.B. Edin., has been appointed House Surgeon at the Royal Devon and Exeter Hospital, Exeter.

HINGSTON, CHARLES ALBERT, M.D., B.Sc. Lond., M.R.C.S., has been re-appointed Honorary Physician to the Crownhill Convalescent Home, near Plymouth.

HOWELL, ALFRED, M.D. Lond., has been appointed Honorary Assistant Physician to the Cardiff Infirmary.

KELLAS, ARTHUR, M.B., Ch.B., D.P.H. Aberd., has been appointed Resident Medical Officer at the Aberdeen Sick Children's Hospital.

LEWIS, W. J., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Ystalyfera District of the counties of Brecknock and Glamorgan.

MCELWAINE, THOMAS, L.R.C.S. & P. Edin., L.F.P.S. Glasg., has been appointed Police Surgeon for the Borough of Devonport.

RUDGE, FREDERICK HENRY, L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon at the Torbay Hospital, Torquay.

SHARP, ALEXANDER D., M.D. Brux., F.R.C.S. Edin., has been appointed Consulting Surgeon for Diseases of the Ear, Nose, and Throat at Noble's Isle of Man Hospital.

STEWART, J., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Beith District of the county of Ayr.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Bromyard, in the county of Hereford.

Births, Marriages, and Deaths.

BIRTHS.

FAWCETT.—On April 25th, at 66, Wimpole-street, W., the wife of John Fawcett, M.D., of a son.

GAMAN.—On April 26th, at Caistor House, Caistor, Lincolnshire, the wife of F. R. S. Gaman, M.R.C.S., L.R.C.P., of a daughter.

VISGER.—On April 30th, 1907, at Elm Lodge, Clevedon, the wife of Charles Visger, M.R.C.S., of a daughter.

MARRIAGE.

GAYNER—HEYCOCK.—On April 25th, at Great St. Mary's Church, Cambridge, Francis Gayner, M.A., M.R.C.S., L.R.C.P., to Emily Bertha, elder daughter of Charles T. Heycock, F.R.S., Fellow of King's College, Cambridge.

DEATHS.

HUGHES.—On April 24th, at Bronwendon, Penmaenmawr, North Wales, in his 82nd year, Robert Hughes, M.D.

SKERRITT.—On April 29th, at Ivor House, Durdham Park, Clifton, Bristol, Edward Markham Skerritt, M.D., F.R.C.P., Senior Physician to the Bristol General Hospital, aged 65.

WILSON.—On April 26th, at Denham House, Goldhawk-road, London, W., Enid May, aged two years, youngest daughter of James Wilson, M.D.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (6th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: *Medical and Surgical Clinics.* X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. *Lecture*:—Prof. W. Wright: The Prehistoric and Early Historic Inhabitants of England (with lantern slides).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Dr. J. H. Sequeira: Clinique. (Skin.) 5.15 P.M.: Lecture:—Mr. J. Sherren: Remarks on the Surgery of the Brachial Plexus

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—Cliniques:—9.30 A.M.: Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Medical Out-patient (Dr. Whipham), Throat, Nose, and Ear (Mr. Carson); X Ray (Dr. Pirie).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.15 P.M.: Sir Dyce Duckworth: Medicine. 2.30 P.M.: Operations. 3.15 P.M.: Mr. W. Turner: Surgery. 4 P.M.: Dr. StClair Thomson: Diseases of the Throat, Nose, and Ear. 2.15 P.M.: Special Lecture:—Sir Dyce Duckworth: Treatment of Cardiac Dilatation.

TUESDAY (7th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynæcological Operations. 2 P.M.: Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Dr. J. Taylor: Clinique. (Medical.) 5.15 P.M.: Lecture:—Sir W. R. Gowers: The Diagnosis and Treatment of Sudden Cerebral Lesions.

NORTH-EAST LONDON POST GRADUATE COLLEGE (Tottenham Hospital, N.).—Cliniques:—10.30 A.M.: Medical Out-patient (Dr. Auld). 2.30 P.M.: Gynæcological Out-patient (Dr. Giles), Surgical Out-patient (Mr. Edmunds). Surgical Operations (Mr. Carson).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.15 P.M.: Dr. R. T. Hewlett: Medicine. 2.30 P.M.: Operations. 3.15 P.M.: Mr. Carless: Surgery. 4 P.M.: Mr. M. Morris: Diseases of the Skin.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road, W.C.).—3.45 P.M.: Demonstration:—Dr. Abercrombie: Nose and Accessory Sinuses.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M.: Lecture:—Dr. Batten: Cerebro-spinal Meningitis.

WEDNESDAY (8th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 P.M.: Medical and Surgical Clinics. X Rays. 2.30 P.M.: Operations. Dr. Robinson: Diseases of Women.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. *Lecture*:—Prof. W. Wright: The Prehistoric and Early Historic Inhabitants of England (with lantern slides).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street W.C.).—4 P.M.: Mr. P. L. Daniel: Clinique. (Surgical.) 5.15 P.M.: Lecture:—Dr. J. Horne: Foreign Bodies in the Ear, Gullet, and Air Passages.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—Cliniques:—2.30 P.M.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.15 P.M.: Dr. F. Taylor: Medicine. 2.30 P.M.: Operations. 3.30 P.M.: Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 11 A.M.: Eye. 3.30 P.M.: Special Lecture:—Mr. Cargill: Treatment of Ocular Injuries.

THURSDAY (9th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 P.M.: Lecture:—Dr. R. Hutchison: Mucous Colitis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 P.M.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 P.M.: Medical In-patient (Dr. Chappel). 4.30 P.M.: Demonstration of Medical Cases (Dr. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. G. Rankin: Medicine. 3.15 P.M.: Sir W. Bennett: Surgery. 4 P.M.: Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 12 noon: Ear and Throat. 3.15 P.M.: Special Lecture:—Sir W. Bennett: Some Points in the Radical Cure of Hernia.

CHARING CROSS HOSPITAL.—4 P.M.: Mr. Wallis: Demonstration (Surgical). (Post-Graduate Course.)

FRIDAY (10th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynæcological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. X Rays. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. *Lecture*:—Prof. W. Wright: The Prehistoric and Early Historic Inhabitants of England (with lantern slides).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Dr StClair Thomson: Clinique. (Throat.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—9.30 A.M.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 P.M.: Medical In-patient (Dr. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.15 P.M.: Dr. R. Bradford: Medicine. 2.30 P.M.: Operations. 3.15 P.M.: Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 12 noon: Skin.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.)—3.30 P.M.: Lecture:—Dr. Batten: Acute Ataxia.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road, W.C.).—3.45 P.M.: Demonstration.

SATURDAY (11th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. 2 P.M.: Medical and Surgical Clinics. *X Rays. 2.30 P.M.: Operations. Dr. Robinson: Diseases of Women.*

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich.)—2.30 P.M.: Operations. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 11 A.M.: Eye.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

district medical officers for the purpose of medically examining members of the staff absent on account of ill-health. The conditions laid down by the Board for acceptance by the medical man, supposing that he is appointed, are as follows:—

> "That the district medical officers be paid a fee of 2*s.* 6*d.* for each examination, it being understood that, whenever practicable, the person requiring a certificate should attend at the doctor's residence, and that if this is impracticable the doctor should make an examination at the employee's own residence."

We do not understand why the employee, if ill, could not furnish a certificate which would be satisfactory to the Board from his own medical man. For such certificate the Board should pay, say, 5s.—ED. L.

A NEW CORSET.

WE have had sent to us for inspection a specimen of a new corset to which the deviser has given the ambitious name of the Health Unbreakable Corset. The special feature of this invention is the replacement of the usual steel busks by leather supports at the sides, while the front busk is lined with leather. We have received a favourable report of the corsets from a wearer to whom we gave our sample and who submitted it to a practical trial for a month. The corset is stated to be "more comfortable than any previously worn, gives greater freedom during exercise and work, and none of the busks have broken." There is not any particularly medical feature about the invention, but no medical man is ignorant of the advantages that a good fitting, pliable, and comfortable corset offers to his female patients. As a rule, the cheap corset does not possess the necessary qualities; its pressures are rigidly and badly distributed, its structure causes it both to wear out easily and to lacerate contiguous garments; and æsthetic charms are absent. Mrs. O'Leary, 4, *Cotham-street, Walworth, S.E., seems to us to be* able to supply the public at a reasonable figure with a useful article, for, although as much as 5 guineas can be spent upon the Health Unbreakable Corset, 8*s.* will purchase the humbler makes. The leather in the corsets while quite new may seem a little stiff, but just as new boots in a short space of time accommodate themselves to the feet, so the leather busks accommodate themselves to the wearer's ribs. The use of leather in this way will be a double saving of expense—the corsets should last longer and so should the underclothes worn next to them.

BOOK CANVASSERS.

To the Editors of THE LANCET.

SIRS,—In the *British Medical Journal* of April 20th, p. 968, there appears a paragraph under heading "Book Canvassers." This was inserted at my instigation in the hopes that the medical profession might be placed upon their guard against the firm in question and more so against signing their names to documents permitting a specimen copy to be sent to them. I was astonished to receive the book in question and immediately returned it (within an hour) by registered post. Nevertheless, I was sued and have this morning had to pay £5 5*s.* for the book (which is valueless to me) and £2 17*s.* 3*d.* costs. I am writing in the sincere hopes that you may feel justified in warning all your readers, but especially *county* ones, for I understand *each county will be canvassed* in rotation.—I am, Sirs, yours faithfully,

April 30th, 1907. COLLINGWOOD FENWICK.

THE THERMOS FLASK.

A FEW simple practical experiments suffice to show the number of useful purposes which the Thermos flask can serve. We are not told in what way the flask is so perfectly insulated that it virtually keeps liquids hot for 24 hours or iced liquids cold for weeks, but such is the fact. Tea made in the early morning and placed in this flask is quite hot enough to drink in the afternoon. Liquid food placed in the Thermos flask before retiring to rest will keep its temperature throughout the night. In 24 hours we found that water placed in the flask at an initial temperature of 180° F. fell to 114·8°. The average fall of temperature over 24 hours was thus about 2·7 degrees per hour. The depreciation of temperature is most rapid during the first few hours, the fall later being hardly two degrees per hour. It is unnecessary to point out what a number of useful applications there are to which this ingenious device may be put, ministering, as it can be made to do, to so many domestic comforts. For travellers cyclists, railway passengers, invalids, nurses, and so forth, this invention will come as a real blessing. The specimen flask with which we made our experiments was submitted to us by Messrs. Lawson, Ward, and Gammage, of 5, Hatton-garden, London, E.C.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received —*Wigan Examiner. Daily Dispatch (Manchester), Birmingham Herald, Morning Leader. Daily Telegraph, Morning Post. Standard. Daily Mail. Daily News, Tribune, Manchester Courier Coventry Standard. Aberdeen Gazette Birmingham Gazette, Liverpool Echo. St. Pancras Gazette Sheffield Evening Telegraph, Sheffield Daily Telegraph, Newcastle Daily Journal, &c.*

ON

NEW FACTS IN RELATION TO THE PROCESSES OF NERVOUS DEGENERATION AND REGENERATION.

Delivered before the Royal College of Physicians of London on April 25th and 30th,

BY W. D. HALLIBURTON, M.D. LOND., LL.D., F.R.S., F.R.C.P. LOND.,
PROFESSOR OF PHYSIOLOGY, KING'S COLLEGE, LONDON.

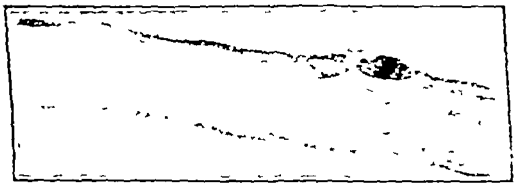
LECTURE II.[1]

Delivered on April 30th.

REGENERATION OF NERVES.

MR. PRESIDENT AND FELLOWS,—The chemical meaning of nervous degeneration, to which I alluded in the first lecture, was studied by Mott and myself in correlation with the anatomical appearances which are observable by the microscope. We found it impossible to study this question without taking into account the closely related subject of nerve regeneration. From the microscopic study of the distal portions of divided nerve trunks we arrived at the conclusion that the activity of the neurilemmal cells has some relation to the development of the new nerve fibres. At any early stage in degeneration their nuclei multiply; later they participate with phagocytes in the removal of the broken-up myelin droplets; subsequently they elongate, and becoming connected end to end lead to the formation of what some have termed "embryonic nerve fibres." These three stages are illustrated by the drawings from micro-photographs shown in Figs. 6, 7, and 8. We were, however, extremely doubtful whether this appearance really indicated the formation of real nerve fibres capable of conducting impulses, and felt that such incomplete observations could not be considered as serious objections to the view of those who, from Waller onwards, have taught that the axis-cylinder is a branch of a nerve cell which grows towards the periphery. In the further investigation of the problem, Mr. Arthur Edmunds joined Mott and myself, and we arrived finally at the conclusion similar to that which Howell and Huber reached 15 years ago, that, although the peripheral structures are active in preparing the scaffolding, the axis-cylinder which is the essential portion of a nerve fibre has an exclusively central origin.

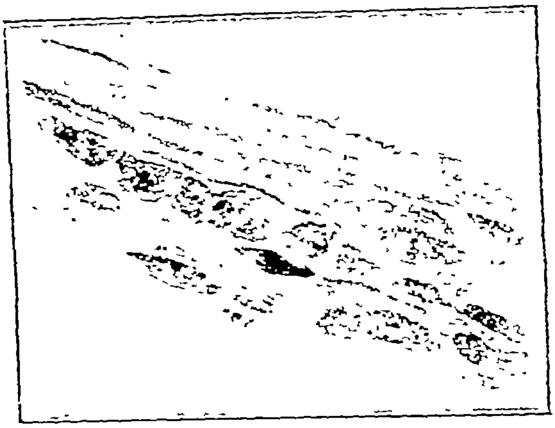
FIG. 6.



Degenerated nerve fibre in a cat's sciatic nerve eight days after the nerve had been cut, showing division of a neurilemmal nucleus. The preparation was stained with logwood, and the drawing is made from Mott's photomicrograph of the preparation by Miss Helen Kelley.

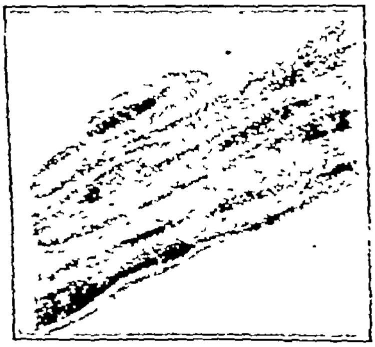
Before I present to you the evidence on which this conclusion is based I must allude first to the work of other observers, for since our investigation started the subject has risen into some prominence. Some workers, such as Purves Stewart and Ballance in this country and Bethe in Germany, have advanced the view that the new fibres have a peripheral origin, while others, such as Langley and Anderson and S. Ramon Cajal, have defended the older Wallerian doctrine. In a preliminary notice which we published a year or two ago of our own work we suggested that the manifest activity of the neurilemmal cells is related nutritionally to the successful repair of a divided nerve, for in situations like the central nervous system, where the neurilemma is non-existent, not only is the removal of degenerated myelin a very slow process but, as is well known, regeneration does not occur. When the nerve is regenerated and conducts impulses the strands of neurilemmal cells are seen to be situated outside the new axis-cylinder and in longitudinal view the latter is thus often concealed; but on transverse section the axis-cylinder is seen to be quite distinct within the sheath, although the neurilemmal nuclei retain an abnormal thickness for some time (see Fig. 9).

FIG. 7.



Degenerated bundle of nerve fibres in longitudinal view in cat's sciatic nerve 27 days after the nerve had been cut. A chain of neurilemmal cells is seen filled with oil droplets (stained black by Marchi's reagent), and evidently exercising a phagocytic action in the removal of degenerated myelin. (Photomicrograph by Mott, drawing by H. Kelley.)

FIG. 8.



Longitudinal view of nerve fibre in cat's sciatic nerve 44 days after the nerve had been cut. By this time absorption of the degenerated myelin was complete and the neurilemmal cells have elongated and in parts joined end to end as described in the text. (Photomicrograph by Mott, drawing by H. Kelley.)

Professor Graham Kerr, in his recent study of the development of motor nerves, has in an entirely independent manner supported this view of the nutritional importance of the neurilemmal sheath. In the fish, *Lepidosiren*, that he has mainly studied, the early motor nerve fibres are at first naked, but later masses of nucleated mesenchymatous protoplasm apply themselves to the nerve trunk, and gradually spread over it. As development goes on the yolk in these masses is used up, their protoplasm becomes less and less conspicuous, and eventually is only to be detected in the immediate vicinity of the nuclei. It is thus clear that the great function of the sheath is as a nutritive organ. Kerr points out that the main function of nuclei apart from reproduction is to control cytoplasmic metabolism, and that the nuclei of the sheath are able to exercise this control over

---

inexcitable. These experiments, like Bethe's, were mostly performed upon young animals—kittens and rabbits, and in some, after a period of nearly two years, no trace of autogenetically formed nerve fibres could be detected. All the medullated nerve fibres found in the peripheral end of a cut nerve, which had been sutured to the central end, degenerated when the central end was again cut nearer the spinal cord; in other words, all the nerve fibres were fibres which were connected with the central nervous system. If the regeneration had been autogenetic, this would mean that every one of them had become united with the end of a nerve fibre in the central stump; on the autogenetic theory this is highly unlikely, whereas it is quite simply accounted for on Wallerian lines. If the number of medullated fibres in the peripheral end was small then the connexion with the central end was found to be slight. If no connexion occurred, then medullated nerve fibres were entirely absent. Bethe admits a variability in the number of medullated fibres, and this again, though easily explicable on the view that such fibres come from the central end, is not accounted for at all by the autogenetic theory. Langley and Anderson further point out that Bethe admits age to be an important factor in the case; in adult animals he has little or no proof of autogenetic regeneration. This is a very weak point, for surely the difference is due to the greater ease with which reunion with central nerves occurs in young and growing animals. Lugaro objects to Bethe's views on much the same lines as Langley and Anderson, and in his latest paper has shown that regeneration of nerves connected with the lower part of the spinal cord does not occur after the lumbo-sacral region of the cord has been extirpated. This is a very striking piece of evidence on the dependence of the growth of fibres on the activity of the cells of the central nervous system with which they are connected. Cajal, from the histological point of view, has made a very complete rejoinder to Bethe's work. He has also controlled his results by noting the effect of stimulating the nerves. By the help of his new silver method he comes to the conclusion that the new formation of nerve fibres in the peripheral stump is exclusively due to growth from the central end. He describes the long and often contorted course of these growing fibres in the swelling at the cut central end, and shows that they ultimately reach their goal—the peripheral stump—in time, and in spite of all hindrances. The greater the obstacles interposed the later do the union and consequent regeneration in the peripheral end occur. He also calls attention to the olive-shaped swelling at the free end of each growing axis-cylinder. These are also figured by Marinesco. I am indebted to the kindness of Professor Marinesco for the next

FIG. 11.

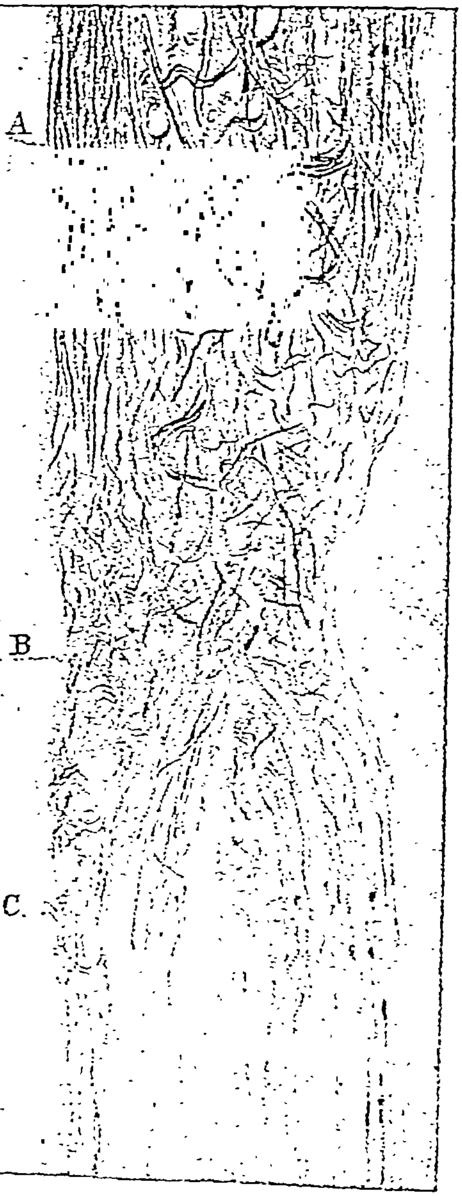
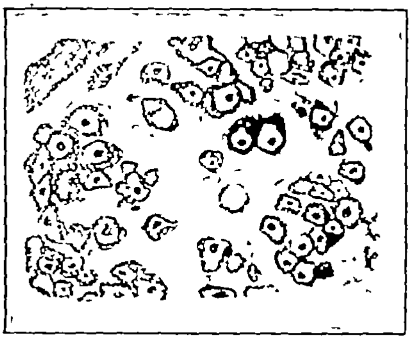
FIG. 12.



Longitudinal section of sciatic nerve of newly born dog, eight days after the nerve had been divided. Union had already taken place. At the extremity of the central end (A) growing fibres are seen running in various directions towards the cicatrix (B); C is the peripheral end into which a few fibres are already penetrating. (Marinesco.)

the active metabolism of the developing nerve trunk which is destitute of nuclei of its own. Connected with this relation is no doubt the active multiplication of these nuclei observed in early stages of nerve regeneration. Whether this control is able to act so far as to produce true nerve fibrillæ in a regenerating fibre, as Kerr further suggests, I am inclined to doubt, for we have never seen anything of the nature of an axis-cylinder or neuro-fibrillæ in the peripheral segment of a divided nerve, provided connexion with the central end is successfully prevented. I am also unable to accept his view that the original nerve trunk exists from the first as a link which increases in length as the animal grows. It is impossible on such a hypothesis to explain how a gap an inch or more long can be bridged across when one excises, as we have done in some of our experiments, a portion of nerve of that length. The union that occurs often very rapidly, even when the ends are not sutured together, must be due to growth of nerve fibres from the central to the peripheral stump, or in the reverse direction. It is also on *a priori* grounds most improbable that the mesoblastic cells which make up the neurilemma could give rise to such a highly specialised structure as the axis-cylinder, which so far as is known is exclusively epiblastic in origin.

FIG. 9.

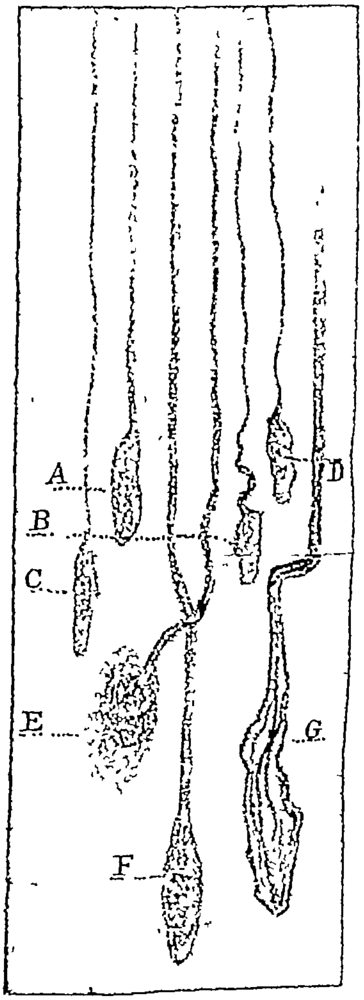


Transverse section of regenerated nerve bundle of cat's sciatic nerve 108 days after the nerve had been cut. The new nerve fibres are much smaller in diameter than those they replaced; the abnormal thickness of the neurilemmal nuclei referred to in the text is well shown in many of the fibres. The preparation was stained with logwood and photographed by Dr. Mott; the drawing from the photograph was made, as in preceding figures, by Miss Kelley.

The propositions maintained by Waller—namely, the integrity of the central end of a cut nerve, the degeneration of the peripheral segment, and its regeneration by means of fibres growing out distalwards from the central stump—were questioned a few years later by Vulpian and Philippeaux. These observers cut nerves in various animals, mainly young ones, excising long portions to prevent union with the central end. Some months later they were surprised to find that the peripheral ends had regenerated and were excitable; to this phenomenon they gave the name of "autogenetic regeneration." These results were regarded with so much scepticism by most writers that some years later Vulpian repeated his experiments. He obtained the same results as before, but this time put forward a new explanation; in fact, he adopted the Wallerian doctrine because he found that connexion with the central nervous system had been re-established by means of fibres growing into the peripheral stump from other nerves in the neighbourhood. This connexion he had missed in his earlier work. He had also, with Philippeaux, observed regeneration in portions of a nerve transplanted under the skin of the abdomen, but as a result of his later work explained this in the same way.

In the revival of the controversy that has taken place within the last few years the position of the disputants has been almost exactly the same as that occupied by Waller and Vulpian more than half a century ago. The evidence which Ballance and Purves Stewart have advanced in favour of autogenesis is purely histological. In the absence of any proof that the so-called nerve fibres are excitable and capable of conducting impulses, I regard it as probable that these observers have mistaken for nerve fibres the chains of neurilemmal cells which undoubtedly form in the peripheral portions of divided nerve trunks. Bethe is at present the most prominent supporter of the autogenetic theory. He finds that the peripheral segments of cut nerves are in young animals after a time excitable without union with the central ends. He does not, however, exclude the fallacy which underlay the old experiments of Vulpian and Philippeaux and which has been more recently pointed out by Langley and Anderson. These observers showed that, in spite of any obvious connecting strand with the central end, new nerve fibres find their way, often by devious channels, into the peripheral stump from nerves in skin and muscle cut through in the operation. At the commencement of their work Langley and Anderson thought they had obtained evidence of purely peripheral regeneration, and it was not until they carried out careful dissections that they convinced themselves that union with the central nervous system had occurred in the manner just mentioned. They therefore once more cut the central portion of the nerve and of any other nerves which might possibly have established a connexion with the peripheral segment of the nerve they had under observation. The second operation would cause degeneration of the fibres which had established a central connexion and leave intact any fibres which had regenerated autogenetically. Even this was not always sufficient to prevent reunion once again of the peripheral end with the central nervous system. But in cases of success no autogenetically formed nerve fibres were found. From eight to 12 days after the second operation no sound medullated fibres were found in the peripheral end, and the nerve was quite

FIG. 10.



Olive-shaped swellings (A to G) at the ends of nerve fibres growing downwards from the central end, 21 days after the nerve had been divided. Differences in the external form of these swellings will be noticed (Marinesco).

inexcitable. These experiments, like Bethe's, were mostly performed upon young animals—kittens and rabbits, and in some, after a period of nearly two years, no trace of autogenetically formed nerve fibres could be detected. All the medullated nerve fibres found in the peripheral end of a cut nerve, which had been sutured to the central end, degenerated when the central end was again cut nearer the spinal cord; in other words, all the nerve fibres were fibres which were connected with the central nervous system. If the regeneration had been autogenetic, this would mean that every one of them had become united with the end of a nerve fibre in the central stump; on the autogenetic theory this is highly unlikely, whereas it is quite simply accounted for on Wallerian lines. If the number of medullated fibres in the peripheral end was small then the connexion with the central end was found *to be* slight. If no connexion occurred, then medullated nerve fibres were entirely absent. Bethe admits a variability in the number of medullated fibres, and this again, though easily explicable on the view that such fibres come *from* the central end, is not accounted for at all by the autogenetic theory. Langley and Anderson further point out that Bethe admits age to be an important factor in the case; in adult animals he has little or no proof of autogenetic regeneration. This is a very weak point, for surely the difference is due to the greater ease with which reunion with central nerves occurs in young and growing animals. Lugaro objects to Bethe's views on much the same lines as Langley and Anderson, and in his latest paper has shown that regeneration of nerves connected with the *lower* part of the spinal cord does not occur after the lumbo-sacral region of the cord has been extirpated. This is a very striking piece of evidence on the dependence of the growth of fibres on the activity of the cells of the central nervous system with which they are connected. Cajal, from the histological point of view, has made a very complete rejoinder to Bethe's work. He has also controlled his results by noting the effect of stimulating the nerves. By the help of his new silver method he comes to the conclusion that the new formation of nerve fibres in the peripheral stump is exclusively due to growth from the central end. He describes the long and often contorted course of these growing fibres in the swelling at the cut central end, and shows that they ultimately reach their goal—the peripheral stump—in time, and in spite of all hindrances. The greater the obstacles interposed the later do the union and consequent regeneration in the peripheral end occur. He also calls attention to the olive-shaped swelling at the free end of each growing axis-cylinder. These are also figured by Marinesco. I am indebted to the kindness of Professor Marinesco for the next

(Marinesco.)

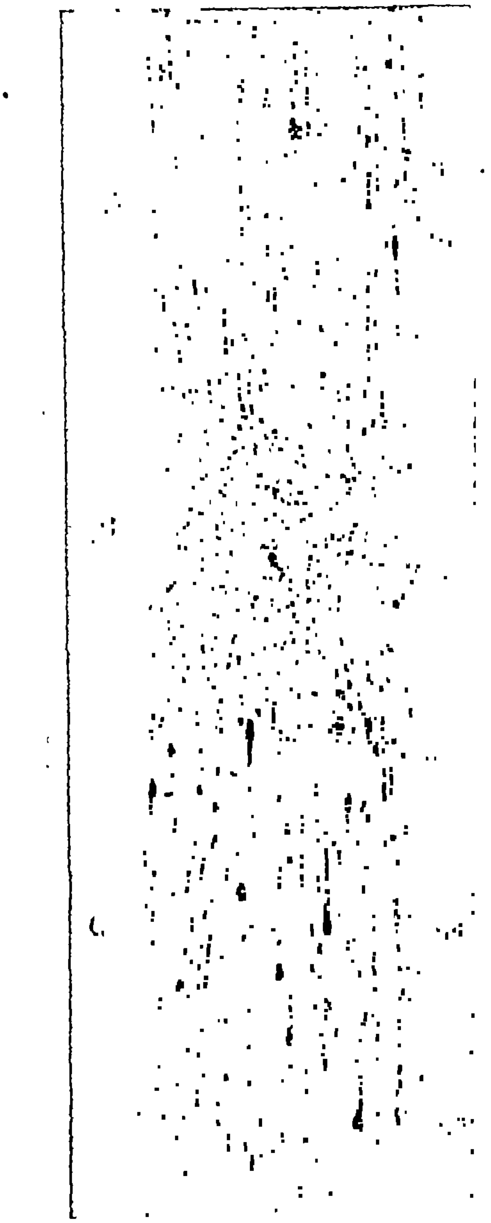
two figures. Fig. 10 illustrates the swelling at the termination of growing axons, and Fig. 11 the convoluted course of the new fibres which is so frequently seen.

Marinesco has passed through the phase so often seen in those who have attacked the problem of nerve repair. He was never a thorough believer in Bethe's views, but in his earlier publications felt obliged to admit that some of his preparations afforded evidence of auto-regeneration. In his last published paper he has recanted these views and is now convinced that auto-regeneration does not take place. I reproduce two very striking illustrations from the numerous figures which he has published. The preparations were stained by Cajal's new method and the reproductions (Figs. 12 and 13) require no comment; they speak for themselves, and ought to carry conviction to those who believe in the autogenetic theory that the Wallerian view is the only possible one to adopt. Marinesco does not believe that the neurilemmal cells act as phagocytes, but otherwise he ranges himself by the side of Cajal and ourselves.

FIG. 13.



Longitudinal section of vagus nerve of dog 21 days after the nerve had been divided. A more advanced condition than that shown in Fig. 12. A is the central end, B the cicatrix of union where the new fibres are seen in great numbers, and taking an irregular course. Into C, the peripheral end, many fibres have already successfully penetrated. m, m′, m″, &c., are the terminal swellings of fibres growing from the central stump, and directed towards the periphery, except in the case of m″, where the twisting of the new fibre in its efforts to grow had at the time when the animal was killed directed the termination backwards. (Marinesco.)

Many surgeons have been steadfast upholders of the autogenetic theory, because they have found that in man (including adults, in spite of Bethe) sensation may rapidly return after freshening up and suturing together the ends of a nerve which had been divided a long time previously. Such clinical observations would be valuable evidence in favour of the "peripheral theory," if it were entirely trustworthy. Mr. Edmunds, then surgical registrar at King's College Hospital, had recently the opportunity of observing carefully one of these cases, and it throws a useful light on the subject. A short time after the operation the patient stated he was able to feel, but these sensations rapidly subsided, and sensation did not really return until months later. The preliminary sensations were doubtless subjective; the irritation of the nerve fibres in the scar lasted some hours, and the sensations so produced were referred by the patient's mind to the original terminals of the fibres.

At the meeting of the British Medical Association in Oxford in 1904 Dr. R. Kennedy of Glasgow brought forward a number of cases in support of the autogenetic theory. Here, again, the genuineness of the early recovery is doubtful, because no care appears to have been taken to distinguish real cutaneous from deep sensibility. Head and Sherren have also recorded a number of surgical cases, but they found no evidence of early recovery; they showed by very careful work that the deep sensibility of the subjacent parts, such as would be excited by the pressure even of the finger, is entirely independent of cutaneous sensation. The fibres subserving this form of sensation run with the motor nerves and are not destroyed by division of all the nerves to the skin. The difficulty of obtaining absolutely trustworthy evidence from patients themselves induced Head to combine with his experiments on animals and his observations on patients an experiment on one of the sensory nerves of his own arm. This experiment gave an opportunity for the study of the phenomena by a trained observer upon himself. He certainly experienced no early return of function, and the date at which sensation did come back coincides closely with the dates obtained in animals by physiologists for the reappearance of new fibres. He has further made the interesting suggestion that the first kind of sensation to return and which is of a vague nature (termed *protopathic*) is associated with the activity of the fine medullated nerve fibres which replace the degenerated ones at an early stage. Return of protopathic sensibility begins about the eightieth day. The more elaborate sensations and power accurately to localise them return at a much later date, and this *epicritic sensibility*, as Head terms it, is usually not perfect until months or even years after the regeneration started. By this time, as was shown by experiments on animals, the fine nerve fibres which subserve protopathic sensation are largely admixed with a later growth of larger nerve fibres, and he believes epicritic sensation is subserved by these.

After this long introduction let me now pass on to describe the experiments which have been carried out by Mott, Edmunds, and myself. Every piece of confirmatory evidence is useful if the upholders of the autogenetic theory are to be convinced they are wrong. In some directions, moreover, our experiments have approached the problem in rather a different way from that followed by other workers. I will arrange what I have to say under five headings:—

(1) *Experiments in which union of central and peripheral ends was prevented.*—We had noticed early in the investigation that the excision of an inch or so of a nerve was entirely inefficient to prevent union of its two ends together; we were also aware of the danger (pointed out by Vulpian in his later work, and by Langley and Anderson, and Lugaro more recently) that the peripheral end may be invaded by nerve fibres growing into it from the nerves in skin and muscles divided in the operation. We therefore made extremely small incisions, and the parts were separated from the nerve trunks by the handle of the scalpel, and with as little cutting as possible. In cats one incision over the buttock allowed us to divide the sciatic nerve high up; another in the ham enabled us to divide the two popliteal nerves. The intervening portion of the sciatic nerve, about

four or five inches long, could then be easily pulled out. Additional security to prevent union with central fibres was in some cases obtained by inclosing the upper end of each popliteal nerve in closed caps made out of small sterilised drainage-tubes about half an inch long. A period of from 100 to 150 days was then allowed to elapse in order that if regeneration was going to occur in the peripheral segments of the nerve it might have an opportunity of doing so. At the end of this time the animal was again anæsthetised and the nerves were tested by electrical stimulation. In all cases they were entirely inexcitable to strong faradic currents, and the wasted muscles supplied by these nerves had also largely lost their power of response to this form of stimulation. To the naked eye the nerves were pale. The animals were then killed and the nerves subjected to microscopical investigation, but they were found to show no trace of regeneration. The chains of neurilemmal cells, without a sign of either axis-cylinder or medullary sheath, were all that could be seen, and in those cases of later date where the nerves had been placed in tubes it was very difficult to recognise any nervous structure whatever in the pieces actually inclosed within the tubes.

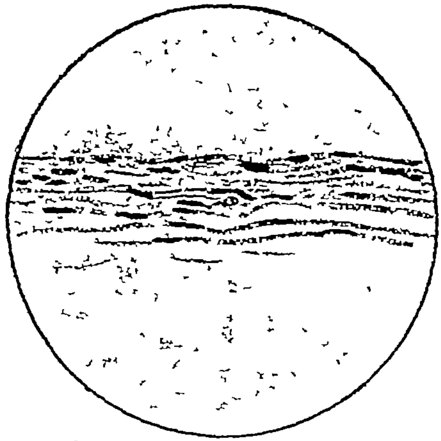
(2) *Experiments on transplanted pieces of nerve.*—As I have already stated, Vulpian and Philippeaux transplanted pieces of nerve under the skin of the abdomen and observed in them what they at first thought was evidence of auto-regeneration, a conclusion subsequently withdrawn by Vulpian. Similar experiments, recently published by Kennedy, are regarded by him as proving absolutely conclusively the autogenetic origin of nerve fibres. He excised a portion of the sciatic nerve and transplanted it into the subcutaneous tissues of the same animal. Six months later he killed the animal and examined the nerve which had been transplanted. He found among a number of degenerated fibres some which were definitely formed with a medullary sheath showing distinct nodes of Ranvier. He concluded that these fibres had been formed by the tissues of the excised portion of nerve. He conceives objectors to this deduction maintaining that these nerve fibres have grown into the sheaths of the transplanted nerve from cutaneous nerves divided in the course of the operation and meets this objection as follows:—

> Such an explanation is, I think, far-fetched, and assumes an extraordinary affinity between the supposed young nerve fibres and the old nerve trunk, an affinity which, if established, would, I am sure, secure almost certain spontaneous union of nerve trunks after division, unless very extraordinary barriers were placed between the divided ends
>
> The number of cases, however, in which secondary suture has to be performed shows that divided nerves cannot be confidently left to Nature to repair, which I am sure might almost uniformly be the case did such strong affinity between young nerve fibres and the distal degenerated segment exist.

It has, however, been shown that a large nerve trunk on division curls up at the end, forming a contorted leash of fibres. Further, a nerve trunk on division retracts and a considerable amount of scar tissue is formed This cicatricial tissue by the time the nerve has begun to regenerate has become dense fibrous tissue. In the case of nerve trunks, therefore, "extraordinary barriers" are the rule. Moreover, in spite of such barriers, spontaneous union often occurs, and in animals when the cut is made more cleanly than occurs in an accident in man and when antiseptics are used, the amount of cicatricial tissue formed is less and union may be confidently anticipated without suture, either immediate or secondary. In the case of small nerve trunks the case is also different; for example, after operations involving extensive skin incisions anæsthesia is always found on one side of the incision, varying in extent according to the direction of the incision and the number of cutaneous nerves divided. It is, however, the rule for these anæsthetic areas to recover completely.

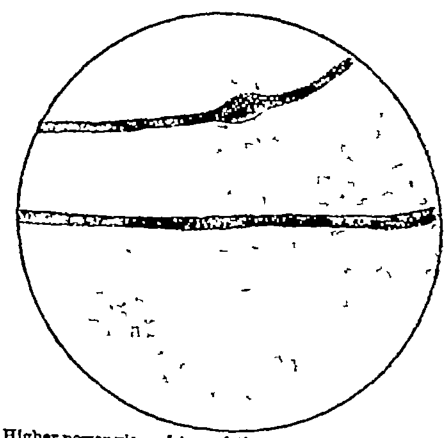
Again, when a longitudinal incision is made through the rectus abdominis muscle, it is very rare to find any permanent paralysis of portions of the muscle, although division of its nerves must be very common. Temporary paralysis, of course, must take place, but there is so little fear of ultimate paralysis and atrophy of the muscle that many surgeons prefer an incision through the rectus to any other method of performing laparotomy. To study this point further we repeated Kennedy's experiment, with the variation that a portion of a nerve was not only inserted underneath the skin, but a similar portion was inserted into the peritoneal cavity. The portion of sciatic nerve which had been previously removed from the same animal was laid on the anterior stomach wall. A row of Lembert sutures of catgut was then passed so as completely to inclose it in a sheath of stomach wall lined by peritoneum. In this way there was no possibility of nerve fibres growing in from the skin, and but little possibility of their coming from the stomach. As a control experiment a wisp of catgut was enveloped in the stomach wall in a precisely similar manner. After 150 days the animals were killed and the nerves examined. In those cases where the nutrition of the nerve had been effectually maintained the nerve could be readily seen both in the stomach wall and under the skin. It was thinner and more transparent than when it was inserted. It was examined in teased specimens and in sections. Each fibre looks like a long tube; there is no trace of a medullary sheath, neuro-fibrillæ, or axis-cylinder. At the point where the nucleus is situated there is usually no increase in the diameter of the fibre, the nucleus being either central or projecting into a central lumen In some fibres, on the other hand, there is a distinct swelling at the site of the nucleus and a considerable amount of protoplasm accumulated around it. These appearances are illustrated in Figs. 14 and 15. They are merely those which have been so often described in the peripheral segment of a divided nerve in which regeneration has not occurred and which all observers agree are due to neurilemmal activity.

FIG. 14.



Low power view of the appearances presented in a piece of nerve transplanted into the peritoneum 150 days previously (A. Edmunds.)

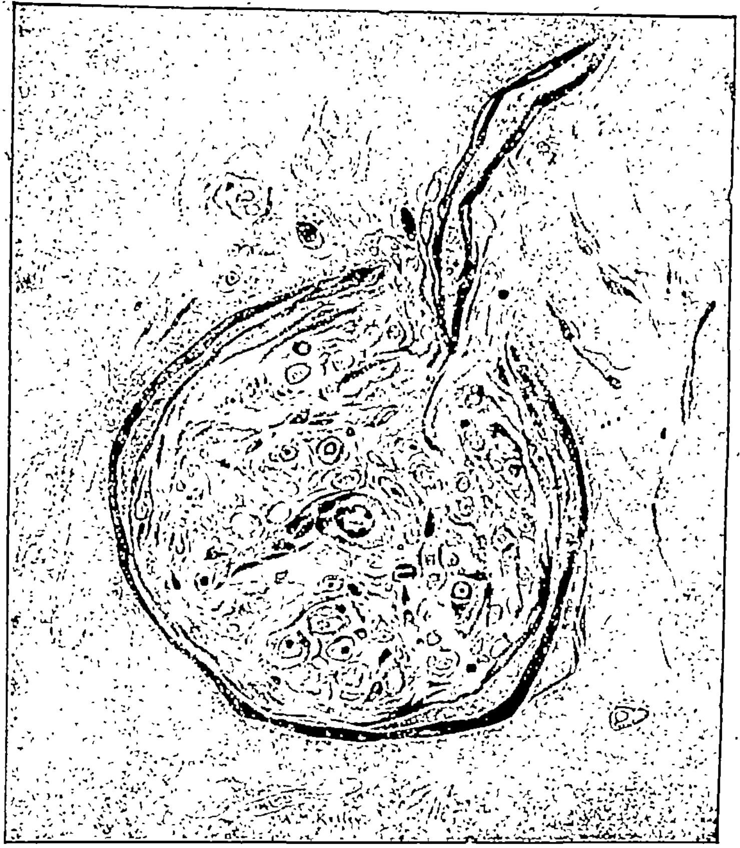
FIG. 15



Higher power view of two of the fibres (A. Edmunds.)

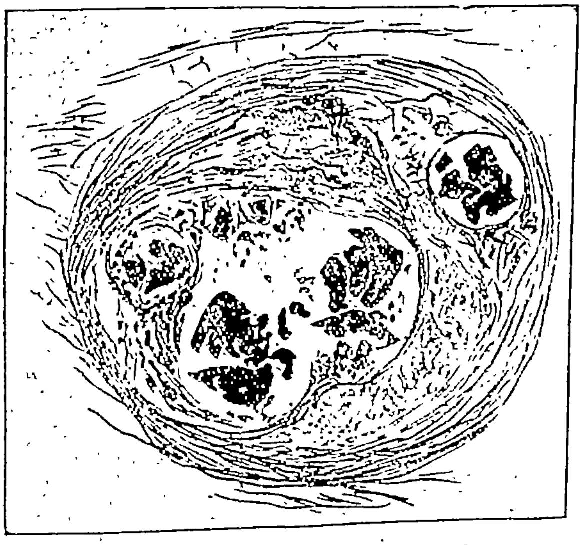
In cases where the nerve had been transplanted under the peritoneum, in which situation invasion by neighbouring nerves is nearly impossible, no medullated fibres could be found. In those cases where the nerve was transplanted under the skin careful search revealed the presence of a few medullated fibres It is difficult to explain the paucity of these fibres on Kennedy's hypothesis that they have formed autogenetically, seeing all the fibres were under precisely the same conditions; but it is easy to account for it if our view is adopted that the well-formed fibres were a few stray ones which had grown into the transplanted bundle from nerves cut through in the operation. The next figure (Fig. 16) illustrates how a blood-vessel breaks through the sheath into the substance of a degenerated nerve bundle, and from this it is a very small step to the irruption of nerve fibres into the interior of a transplanted nerve. The connective tissue between and around the bundles of nerve fibres retains its normal relationship but any structure of a similar shape becomes inclosed in a fibrous sheath unless it is completely absorbed. This is well illustrated in Fig. 17, which shows a transverse section of a strand of catgut which had been enveloped in the stomach wall; the connective tissue is seen to be organised around the catgut threads, forming a framework which strongly suggests the sheath of nerve fasciculi. Marinesco has shown that if a transplanted nerve is obtained from another species of animal (hetero-transplantation) it does not undergo the usual Wallerian changes, but is completely necrosed, just as the blood corpuscles of one animal are destroyed by the body fluids of another. The surgical method sometimes adopted of employing an animal's nerve to assist the regeneration of an excised portion of nerve in man is, therefore, rather a hindrance than a help.

FIG. 16.



A small blood-vessel entering the sheath of a fasciculus of transplanted nerve, as described in the text. 230 diameters. (Drawn by Miss Kelley from Mr. Edmunds's preparation.)

FIG. 17.

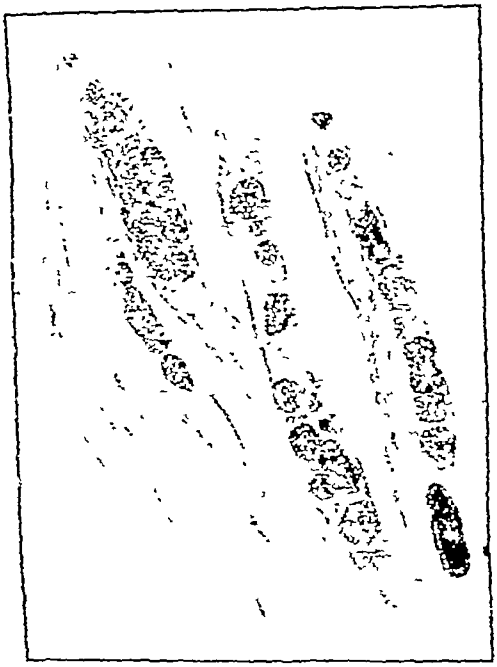


Transverse section of strand of catgut which has become surrounded by a sheath of connective tissue after being transplanted to beneath the peritoneum as described in the text. (A. Edmunds.)

(3) *Experiments on the degeneration of regenerated fibres.*—We performed these experiments at the suggestion of Professor Gotch. A large nerve was divided in an animal and the ends were sutured together with sterilised silk. After a sufficient length of time had elapsed restoration of function led us to suppose that regeneration had occurred. A second operation was then performed in each case. The animal was anæsthetised and the nerve was exposed; the union of the two ends was found to have been accomplished and the nerve was excitable both above and below the junction. A piece of nerve about half an inch long was then excised an inch or so below the jon tion. On histological examination of this a traces of degenerated products were foun to have disappeared and it was made up fine nerve fibres, many of which had acquire a delicate medullary sheath. After th second operation the wound was closed an the animal allowed to live ten days longer it was then killed and the nerve both belo and above the second cut was examine No degeneration was found in the ner fibres above the second lesion, but Walleria degeneration was shown by the March method to have occurred in the medullate fibres of the peripheral portion which was quite inexcitabl The direction of degeneration is the direction of growt so this experiment shows that the growth of th nerve fibres had not started from the periphery centra wards but in the reverse direction. Fig. 18 is fro a drawing of the degeneration seen in a teased pre paration of the peripheral segment after the secon operation.

We noted an interesting point in these experiment which illustrates the great rate at which the regene rating fibres grow. Although only ten days ha elapsed between the second operation and the killin of the animal, and although quite half an inch of nerve had been excised and no efforts made t approximate the ends, yet there was usually a well- marked strand of union uniting the two segments. We think that these experiments, taken in conjunction with the somewhat similar experiments already alluded to in the work of Langley and Anderson, in which, after union of the two ends of a divided nerve, degeneration in the regenerated fibres sets in after a second operation of dividing the central end of the nerve nearer the spinal cord, conclusively prove the regenerated fibres to be in anatomical continuity with the fibres in the central end, and so with the central nervous system. They thus serve to prove the doctrine that the regenerated fibres have grown from those in the central stump. At the time that we undertook these experiments we were under the impression that they had never been previously performed. But on looking up the literature we find this is not the case. Like so much of the present work set oing by the revival of the autogenetic theory this experiment has also been performed by others. As long ago as 859 Philippeaux and Vulpian did it and obtained the same esult as we have; we can hardly doubt that this formed ne of the factors that later led Vulpian to abandon the utogenetic theory.

FIG. 18.



Wallerian degeneration of regenerated nerve fibres in a cat. Marchi method of staining. 80 diameters. (Drawn from a teased preparation made by Dr. Mott by Miss Kelley.)

(4) *Experiments on the rate of medullation in regenerating nerves.*—Another very important piece of evidence which supports the general view I am advocating was obtained by examining regenerated nerve fibres in various parts of their course. There is always a noticeable difference between the amount of medullation in the regeneration of motor and sensory nerves, that in the latter advancing more rapidly. It was therefore necessary for us to examine the same bundle of fibres in different parts of their course. In specimens obtained from 80 to 90 days after the nerve had been cut the peripheral portions near the junction contained numerous myelinated fibres, whereas some inches lower down myelination was less distinct and the number of fibres which had been invested with a medullary sheath much fewer in number. We illustrated these appearances by coloured drawings in our paper recently read before the Royal Society. It can hardly be doubted that the medullary sheath is a developmental appendage of the axis cylinder; it appears in the fibres of the central nervous system, where the neurilemma is absent; it degenerates with the axis cylinder when a nerve fibre is cut and completeness of function is associated with its appearance in development and with its reappearance in regeneration. I therefore think we are justified in concluding that the late appearance of this sheath in those portions of the regenerating fibres which are most distant from the place where the nerve was originally cut is a conclusive piece of evidence in favour of the view that the new nerve fibres have grown from the central end in a peripheral direction.

(5) *Experiments on the influence of stimulus on regeneration.*—These experiments were performed on rhesus monkeys. A monkey's arm was rendered immobile by the division of a number of the upper posterior roots on one side. In order to be perfectly certain we usually divided from the second cervical to the second or third thoracic roots inclusive. The anterior cornual cells from which the corresponding motor fibres originate are thus not subjected to stimuli from the periphery, and, as Mott and Sherrington were the first to show, the arm is as much paralysed as if the anterior roots had been cut. We, however, again noticed in some of these animals under the influence of strong emotion that some efforts were made to move the paralysed limb. These efforts are ineffectual and are limited to associated movements in the upper segment of the limb; fine movements were never noticed. When the animal is living in its cage under ordinary conditions it makes no effort to move the limb, which, when a sufficient number of roots have been entirely cut through, hangs helpless like a flail. After the healing of the neck wound produced by the cutting of the posterior nerve roots was accomplished, a matter usually of one or two weeks, a large nerve in the arm was then divided and the ends were sutured together. The corresponding nerve was cut and sutured on the non-paralysed side as a control experiment. The animal was finally killed; the interval between the operation and death varied in different experiments, but the best time for making the observation we finally determined to be between 60 and 70 days after the nerves had been cut. This is a date when regeneration is perfectly evident, but not too far advanced; it therefore permits of comparative observations on the amount of regeneration. Union of the divided nerves occurs on both sides of the body and in our early experiments the nerve on the side corresponding to that on which the posterior nerve roots had been divided was found to be the less excitable to the faradic current. Histologically this nerve showed a looser texture and new nerve fibres, though present, were less numerous than on the control side. In these early experiments also we found that the posterior cornual cells in the cervical region were atrophied and that there was a considerable overgrowth of neuroglia tissue in the posterior horn. Further examination of these spinal cords showed, however, that there had been a considerable number of small hæmorrhages, sufficient in some cases to cause degeneration in various descending tracts in the cord. It therefore became quite possible to explain the effects observed by this complication.

In several of the later experiments in which cord hæmorrhages did not occur to any great extent we have been unable to detect any marked changes in the anterior or posterior cornual cells, or any difference to stimulation or in microscopic structure between the regenerated nerves of the two sides. This conclusion fits in with some experiments of H. K. Anderson. He showed that in developing animals section of all the posterior roots connected with a limb exercised no retarding influence on the development of the corresponding anterior roots. Warrington has stated that when posterior nerve roots are cut the anterior horn cells undergo the chromatolytic change associated with inactivity; after some time (from 30 to 74 days) chromatolysis disappears, but the total number of cells on the side of the lesion is lessened; after periods of from 150 to 223 days from the initial lesion the wasting of the grey matter is very marked. We have never observed these changes even although in one case the cord was examined in an animal killed 17 days after the division of the roots. At any rate, it was not possible by looking at the anterior nerve cells of the two sides to tell which was the side on which posterior roots had been divided. In further experiments we sought to cut off the cerebral influence by removing the cortical arm area of the opposite side in addition to dividing posterior roots. In this case also the regenerated nerves of the two sides were equally responsive to stimulation, and histological evidence of any marked difference between them was also lacking.

Finally, we still further reduced the action of innervation currents on the anterior cornual neurons by cutting off the stimuli which enter by the posterior roots as well as those which descend from the brain. The latter was accomplished by combining either a semisection or a complete transection of the cord in the mid-thoracic region with the division of the posterior nerve roots which correspond to the lower limb of one side. The two sciatic nerves were then divided and sutured and, as before, an interval was allowed to elapse until these nerves regenerated. Here, again, the result was negative. Both nerves regenerated equally well and both were equally responsive to excitation. It is, therefore, quite evident that the paths which even in these circumstances remain open (commissural and association tracts) are sufficient to maintain the activity of the anterior cornual cells in the sprouting forth of new axons in a peripheral nerve although they may be insufficient to induce those cells to send effective impulses along them. It is also evident that in order to reduce the activity of the anterior nerve cells to a sufficient degree to prevent the regeneration of their axons, it would be necessary to insulate a group of them so as to prevent all impulses reaching them from every part of the nervous system. We did not see our way to accomplish such an operation without interfering with the blood-supply of such an island of cord matter. The nearest approach we have obtained to such a condition of things is to be found in those early experiments in which hæmorrhages and neuroglial overgrowth occurred as a complication. Here certainly the diminution in the number of regenerated fibres points to a reduced activity or, it may be, destruction of some of the anterior cornual elements, but in either case these experiments, so far as they go, are in favour of the view that new nerve fibres grow from central axons and are not formed autogenetically.

GENERAL CONCLUSIONS.

I put forward the foregoing five sets of experiments as a contribution to the discussion now in progress as to whether the regeneration of nerve fibres is autogenetic or not. These experimental methods approach the subject in different ways and in no one case was any evidence forthcoming of auto-regeneration. The facts recorded, taken in conjunction with those published by such observers as Cajal and Langley and Anderson, form, on the other hand, strong pieces of evidence in favour of the Wallerian doctrine that new nerve fibres are growths from the central ends of divided nerve trunks. The experimental facts recorded by those who, like Bethe and Kennedy, hold the opposite view are susceptible of easy explanation, mainly on the lines emphasised by Langley and Anderson of accidental and unnoticed connexion of the peripheral segments with the central nervous system by means of other nerves cut through in the operation. If such connexion is effectually prevented real regeneration of structure and restoration of function never occur. Moreover, the regenerated fibres always degenerate in a peripheral direction, and in a peripheral direction only, when the link that binds them to the central nervous system is again severed. Perhaps the most striking of the new facts I have mentioned is in reference to the development of the medullary sheath; this appendage of the axis-cylinder appears earliest at situations near the point where the ends of a nerve have been joined together and reaches the distal portions later. What takes place in the peripheral segment of a divided nerve is a multiplication, elongation and union into long chains of the neurilemmal cells. The same change is even more vigorous at the central termination of the cut nerve; and the view of the phagocytic and nutritive function which we *attribute to this sheath* has been supported independently by some striking observations of Graham Kerr to which I have fully referred. At the central end this nutritive function is effective and provides for the nourishment of the actively lengthening axis-cylinders. At the peripheral end, unless the axons reach it, it is ineffective in so far as any real new formation of nerve-fibres is concerned. If, however, the axons reach the peripheral segment the work of the neurilemmal cells has not been useless, for they provide the supporting and nutritive elements necessary for continued and successful growth. The neurilemmal activity appears to be essential, for without it, as in the central nervous system, regeneration does not take place.

Note.—Since this lecture was prepared for publication Dr. Bethe has sent me a copy of his latest paper on regeneration (*Pfluger's Archiv*, vol. cxvi., p. 385, 1907), in which he defends his views. He now admits that in adult animals no regeneration of medullated fibres occurs autogenetically; he does not, however, state at what age animals lose their power of autogenetic regeneration or explain how it is that after a certain date an animal repairs a divided nerve in the exactly contrary manner to that it would have adopted if the nerve had been cut before that date. He also again admits that a regenerated nerve when cut degenerates in a peripheral direction only but denies that degeneration has anything to do with direction of growth. He further states that on one or two points we had misquoted him in our Royal Society paper; for this we can only express our regret and in the present lecture I have rectified the error. The paper is largely polemical and is directed against Cajal, Marinesco, and others as well as *ourselves.* I can, however, find no fresh work in it sufficient to convince me that autogenetic regeneration of nerve ever takes place.

Bibliography.—The chief references to the original work done on this subject are given in a paper by Mott, Edmunds, and myself in the Proceedings of the Royal Society, B., vol. lxxviii., 1906, p. 259. The principal papers which have since appeared are the following: E. Lugaro, Neurologisches Centralblatt, vol. xxv., 17, p. 786; G. Marinesco, Jahrbuch für Psychologie und Neurologie, vol. vii., p. 141, 1906; Perroncito, Bolletino della Società Medico-Chirurgica diu Pavia, 1905. All three papers defend the Wallerian doctrine. The following paper by Warrington, Journal of Physiology, vol. xxx., p. 503, 1904, was not mentioned in our Royal Society paper. Braeunig: Archiv für Anatomie und Physiologie, Physiologisches Abtheil, 1903, p. 251, confirms Warrington's views.

A Lecture

ON

THE CAUSES OF CARDIAC MOTION AND DISORDERED ACTION.

Delivered at the London Post-Graduate College and Polyclinic

BY ALEXANDER MORISON, M.D. EDIN,
F.R.C.P. LOND. & EDIN.,
PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL.

GENTLEMEN,—It appears to me that we may occasionally with profit devote a certain amount of time to an inquiry into the "causes of things" and I shall venture, with, I hope, your acquiescence, to go even further and say that such a procedure is often of practical utility. Thinking so myself, I propose in this lecture to deal with certain facts and opinions which in recent times have materially altered the view which some take of the nature of disorders of cardiac motion, although I do not find myself able to subscribe in their entirety to some of these notions, if I have apprehended them aright.

The heart, like every other organ exercising a particular function, is built on an essentially tripartite basis. We have a cell having properties peculiar to itself, blood which nourishes that cell, and nerves which "govern its action," to use the conventional phrase. The central nerve cell itself may be said to have afferent and efferent processes, of which the former may be regarded as its essentially stimulating "nerves," having their roots in living matter and connecting life with life throughout the body—life touching life through the central nervous system as blood flows through its channels from and to that organ which Harvey likens to the sun of our world in perhaps the finest chapter of his immortal work. So, also, the roots of action or motion, as a whole, may be said to be in "feeling" or in "irritability," if you prefer that term, and the senses of the body corporate may be held to touch the sources of "life" in the midst of that "Nature" in Which and by Which or Whom all living things "move and have their being." If one of the factors in this tripartite combination suffer, the others of necessity suffer more or less with it, for the functional activity of the organ depends upon their duly balanced and harmonious coöperation.

I do not suppose this position is seriously assailable, but thought, as directed to the point, has tended at one time to ascribe the major influence to one factor and at another to another. The blood as a medium common to the two others, and without the nutritive influence of which neither of them could exercise any function long, has entered of late less into the controversy as playing a predominant rôle in the exercise of particular function than the other two, and even as regards these their own sphere is sufficiently evident, except in a borderland of detail in function which some regard as chiefly exercised by the cell and others by its nerve-supply. The controversy, that is, as affecting the heart, lies chiefly between so-called myogenists, who advocate the claim for preponderant action to the muscle cell in the heart, and neurogenists, who claim that details in the function of the cell are chiefly dependent upon the nervous influences brought to bear upon that essential factor. We may, therefore, direct attention in the first place to the claims of the muscle cell.

It is unnecessary and would be quite out of place on this occasion even to attempt to sketch the evolution of thought *as regards the character of muscular action* in the heart. It is as old as direct observation of the active organ. Knowledge of the sequence of auricular and ventricular action and of the contractility of small detached segments of the heart is as old as Harvey. To come to later times the arrangement of muscular fibres in the heart has been more minutely amined (among others) by Professor J. Bell Pettigrew and s dissections of the boiled organ may still be seen in the useum of the Royal College of Surgeons of England in ncoln's Inn Fields. At the present time there is no one this country who has more fruitfully directed attention to e anatomical study of the heart than Professor Arthur eith of the London Hospital, to whom I am indebted for e opportunity of showing you specimens bearing upon me points in this lecture, and some of whose illuminating apers have been published in THE LANCET.

Careful and elaborate as were Professor Pettigrew's dissec-ons they did not show a direct continuity between the uricular and ventricular musculature. This was until com-aratively recently undiscovered and not until still later was s complete anatomy known, if, indeed, we can even now egard that to be the case.

The researches of Stanley Kent, His junior, Retzer, renig, Tawara, and Keith have shown in considerable etail that a peculiar system of muscular fibres connects the uricles and ventricles by a route of perfect continuity. It s present in all vertebrate animals and is even found in the mbryo, but it is very well developed in the sheep and in the alf, in which, as Professor Keith has remarked, it may be een with almost diagrammatic distinctness. This muscular ract arises in the right auricle below the coronary sinus, asses along the right side of the septum auricularum, dives elow the septal cusp of the tricuspid valve, and divides into wo main branches at the auricular end of the septum entriculorum. There the right branch courses down the ight side of the septum to be generally distributed to the walls and papillary muscles of the cavity, and the left, piercing the fibrous membrane, passes over the top of the septum into the left ventricle, entering that chamber at the base of the non-coronary cusp (as Keith conveniently calls it) of the aortic valve, and, as in the right ventricle, is generally distributed over the surface of the chamber and into its papillary muscles. The fibres of this system differ from the usual type of cardiac muscle fibre. They are smaller and paler than the latter at their commencement and have smaller nuclei, become larger and merge into the peculiar cellular system of so-called Purkinjean fibres at a later point in their course, and, as Tawara has shown, ultimately end in cardiac muscle fibres of the ordinary type. Some bands in the ventricles hitherto regarded as tendinous are now known to be strands of pale muscle belonging to this system. Purkinje first noted fibres of the type called after his name in 1845, but these were regarded until recently as embryonic remains or pathological products. I think it is not too much to say that we have now a clear conception of their anatomical relations, although much observation is still needed to settle important points in their physiological function and the mechanism by which this is exercised.

Peculiarity of anatomical organisation argues a corresponding specialisation of physiological function, and Hering and others, including Erlanger, have shown that section or clamping of this so-called bundle of His has the effect of dissociating the regular sequence of auriculo-ventricular contraction. Hence it has been assumed that the function of this system of muscular fibres is to conduct the stimulus to contraction from the auricles to the ventricles, and hence also that alterations in the auriculo-ventricular rhythm are frequently due to disturbances or interruptions in the course of these muscle fibres, which thus manifest the property of "conductivity," as it has been termed, to distinguish it from the neural transmission of impulse. It is to Gaskell in this country, to whom we also owe so much of our knowledge of the nervous endowment of the heart, that we are chiefly indebted for the present conceptions of this among other properties of the cardiac muscular fibre, and Englemann in Germany has given powerful support to these views.

Conductivity is only one of the properties inherent in cardiac muscular fibre, according to the view now held by some observers. The other essential properties are the independent power to build up a "stimulus" to contraction which enables the muscle cell, by its likewise inherent "excitability," to manifest its "contractility," its regularly repeated contraction or "rhythmicity," and its degree of average contraction, "tone," or "tonicity," as myogenists term it. The muscle cell is thus assumed to have excitability, contractility, rhythmicity, conductivity, and tonicity, which constitute its five-fold independence. These terms are not in themselves new, but their independence of nerve influence has of late been emphasised. Like all other muscle, the fibres of this system are, however, endowed with nerves, although details in their innervation still demand research. But it is assumed that, while the nervous system "controls" their action, it is no more the cause of any of their activities than, as Professor Wenckebach (one of the most ingenious exponents of this myogenic theory) declares, the action of the horseman in manipulating the reins is the essential cause of the various manœuvres and condition of the horse itself.

The arguments employed in the establishment of this independence of cellular organic action have varied, as scientific theories are bound to vary, in the light of fresh facts. It was argued at one time that certain rhythmically acting organs, or portions of organs, were devoid of peripheral nerve cells and even of nervous endowment. The later discovery, however, of these structures in such situations has altered conceptions built upon this assumed nervelessness. But, even now, there is in some instances a vague ascription of a merely trophic value to the nerve-supply in such situations, or a definite limitation of nerve influences to a strictly regulating rôle, as distinguished from one in which they may be regarded as productive of stimulus, excitability, conductivity, and tone in the individual cell. Divergent as these views apparently are, it seems not unreasonable to expect that the truth will be found to lie in a compromise between them and that some of the properties of the muscle cell may be found to be more dependent upon nervous influence than is at present thought to be the case. Indeed, there are not wanting signs that such an enlargement of view has already begun. The nervous system, which lay dormant in the myogenic description of cases for a time, plays a considerable part, for example, in the account of a case of bradycardia published by Dr. John Hay and Dr. Stuart A. Moore in THE LANCET.[1]

I am not aware that it has ever been urged that the power of the visceral muscle cell to manifest contraction and the cessation of contraction—that is, contractility—is in the first instance due to the influence of the nervous system any more than that the secretory power of any glandular cell is owing primarily to such influence. But experimental physiology has amply proved that the functional activity both of the cardiac cell and of glandular cells may be modified by the action of the nervous system, and the question arises whether the attribution to a cell of a complex of independent properties is not really the multiplication of one essential property through the influence of the nervous system into the several properties which serve to explain its various conditions.

The anatomical argument for the independence of the cardiac cell in its complex aspect is drawn in the first instance from embryology. His showed that rhythmical action could be observed in cardiac muscle at a time prior to its endowment with nerves. This would doubtless be a strong argument were we certain that this embryonic rhythmicality was really quite devoid of nervous influence. We must remember that if nerves have not actual touch of the muscle, when it first exhibits the property in question they are, nevertheless, like the muscle itself, in process of growth, and not only so, but that the nerves are growing in a direction which will ultimately carry them to the cell. Is it not possible that they may in these circumstances exercise an influence from a distance upon nascent muscle through the medium of the evolving structures and the nutrient fluid in which the parts grow, on some such principle as the transmission of messages by wireless telegraphy to a recording surface? It may be objected that such a notion is merely fanciful, and I readily admit that it is so, but it must also be remembered that embryology is a matter of anatomical observation, not of experimental physiological research, and it is difficult to imagine that it can ever be otherwise. But, it may be urged, that whatever doubt there may be on this point there is none about the orderly auriculo-ventricular contraction of the eviscerated heart—of the heart detached from the central nervous system, and it may be maintained that reflex actions carried out by peripheral portions of the nervous system are against the finding of the experimental physiology of the moment.

There are some considerations which appear to call in question the finality of the above conclusion. Thus, there appears to be a relation between the constancy or degree of rhythmical muscular action in the viscera and the character of their nerve-supply. The heart and intestines, for example, which are constantly rhythmical, are richly supplied with peripheral ganglionic cells in their nervous endowment, while the uterus, an organ in which rhythmical action is chiefly manifested for only a short period during parturition, so far as I have been able to ascertain by personal investigation, is quite devoid of such cells on the nerve trunks which course through the organ, although it is in connexion with the sympathetic system by extra-uterine ganglia. To ascribe a merely trophic influence to the peripheral ganglionic cell does not carry us much farther, nor does it convince us that there is not a certain autonomy in the peripheral nerve cell, even although, like delegated authority generally, its permanence or persistence may be dependent upon a more central organisation. It does not therefore follow, I would submit, from a more exact knowledge of the muscular structure of the heart that the rôle of the nervous system is merely that of regulating the action of the muscle cell, excited in various degree by a self-generated stimulus. The importance of this conclusion, if correct, for a just estimate of the nature, causes, and treatment of motor disturbances of cardiac action cannot be disputed. Erlanger has shown that the clamping of the band of His interrupts more than muscular conductivity. It also interrupts when complete the transmission of nerve influence by way of the vagus and what is true of this experiment is doubtless also true of that in which the tract is divided by the knife. Due weight must, however, be given to the important observation made by Hering and other physiologists that it is division of the tract at the auriculo-ventricular boundary and not section of the heart muscle elsewhere which results in the dissociation of auricular and ventricular contraction.

---

[1] THE LANCET, Nov. 10th, 1906, p. 1271.

The five-fold qualities or properties of cardiac muscular action are taken to denote a similar variety of conditions of the muscle cell and the myogenic view is that these properties must be regarded as independent of one another. That is, that one or more may be increased or diminished as the case may be without the rest being affected. Thus stimulus production may be diminished while excitability is increased or average, and the latter may be altered without conductivity and contractility being changed.

It is not disputed by the most convinced myogenists that the nervous system may inhibit or increase one or all of these properties of the muscle cell, but the essential participation of the nervous system in the production of conditions of which these manifested properties are a result is denied by them. Inasmuch, however, as we are still ignorant of the nature both of the so-called muscle stimulus and of nervous influence, it follows that dogmatism on this point, either from the myogenic or neurogenic standpoint, is out of place, while any heat of controversy on the subject is as irrational as the *odium theologicum*. It is rather an interesting scientific question in the discovery of the truth of which all are concerned, because, to quote an old saw, "knowledge is power," and, as practical physicians, all interests us which we can utilise in the management of disordered function. The myogenic position is, however, more difficult to establish in some respects than the neurogenic because the stimulus and its consequences are sought by the myogenist in one and the same structure, while the registration of the effects of nerve stimulation are seen not in the nerves but in the organ innervated. The behaviour of the heart may be noted as a consequence of stimuli applied to its nerve-supply and, as a matter of fact, we do know, as I have already stated, that the action of the cardiac muscle may be retarded, hastened, augmented, and depressed through the direct agency of the nervous system, the importance of which fact, for practical purposes, cannot be gainsaid whatever names may be applied to the various phases in the complex muscular states, which the myogenist regards as acting automatically.

Did the inherent possibility of certain conditions arising not exist, naturally they would not arise. That a strip of muscle detached from the body and variously treated by stimulating or relaxing agencies should show evidence of what is called tone or tonicity or of relaxation, which seems not yet to have been termed relaxicity but depression of tonicity, appears no more marvellous than that water should harden under cold, and ice melt under the influence of heat. Did the water not contain these potentialities the result would certainly not follow. But the change is one of condition under additional influence, not necessarily of independent constitution. Did cardiac muscular tissue not possess the potentiality of manifesting the various states to which the names mentioned have been given, the phenomena they connote would certainly not appear. But it does not follow because this is so that the blood and the nerves do not in life, and with organs intact, induce conditions which have as a natural consequence the various states of muscle mentioned. Even on this showing, however, the blood and the nerves are only general terms for materials which conduct force, as air does heat and cold, and suggest much more complex conditions the full knowledge of which would give us the key to the mystery of life itself, which some are sanguine enough to suppose it may one day be the lot, desirable or otherwise, of some physiologist or physicist to discover.

Certain *pathological* facts, in addition to the interpretation of clinical phenomena, and the results of experimental physiology already mentioned, are regarded as supporting the myogenic position. Thus Stengel found in a fatal case of bradycardia that a calcification of the aortic cusp of the mitral valve pressed upon the point at which the bundle of His enters the left ventricle for distribution. In estimating the value of this fact we should naturally desire some evidence as to the duration of the bradycardia and the length of time for which the calcification described impinged on the conductive tract. The muscular fibres of this tract are stated by Aschoff and Tawara not to participate in the general hypertrophy of an enlarged heart, and Professor Keith corroborates them on this point so far as his present researches have gone. In one case of bradycardia Aschoff found a "severe sclerosis of the small arteries which traverse the knot and principal bundle of the conducting tract," and in another of the same disorder he found "a very marked development of adipose tissue in the same part." He adds, however, that the heart was generally infiltrated with fat and that he could not establish "any actual destruction of the muscle within the main portion o the conducting system." Dr. G. A. Gibson also found in case of "heart-block" cellular infiltration and fibrosi of the band in question, while an examination of the vag gave a negative result. Dr. John Hay has quite recently recorded a case of syncopal bradycardia in which Professor Keith found the fibres of the bundle of His "partially" obliterated. There were, however, periods in which the conducting power of the tract appeared to be good, and Dr. Hay assigns as possible causes of the variation either vagus influence or undue frequency of auricular systole. Needless to add, there was no exhaustive examination of the intrinsic nervous system of the heart.[2]

I merely state the facts related without further comment than that many more such observations will have to be recorded and weighed before a positive conclusion is attained on pathological grounds as to the dissociation of auricular and ventricular action being due to a purely muscular affection of these fibres. Even on physiological grounds one would scarcely expect any gross lesion of the vagi in cardiac *retardation*. We should rather seek it in some evidence of disease in the accelerant nerves which permitted the vagus influence to be exercised unrestrained. But we know that the pathology of the cardiac nervous system is, at present, practically a *terra incognita* and the physiology of the newly discovered conductive tract is still in its infancy. Details in its innervation even are unknown as I have already stated. The importance of the nervous system as influencing cardiac action is, on the other hand, also argued by certain facts which are difficult to explain on the hypothesis of its playing a merely regulating rôle in a muscularly independent organ. The influence of psychical and physical stimuli in producing alterations in the rate, rhythm, and force of cardiac action is among the common-place observations of physiology, experimental and clinical and subjective. Do they do so merely by playing the part of the horseman to the horse, to use Wenckebach's simile, that is, by curbing constant independent properties of the muscles, or by urging them to increased effort? Or does the nervous system augment or inhibit manifestations of muscular action by modifying the production of stimuli or changing their nature? That is, of course, the whole ground of controversy between the myogenist and the neurogenist. There are some recorded clinical experiences which appear to argue that the independence of the properties ascribed to visceral muscle may be matter of legitimate doubt.

---

[2] Professor Keith and Dr. Charles Miller give anatomical particulars of a case of long-standing bradycardia in THE LANCET of Nov. 24th, 1906, p. 1429, in which the muscular connexion between the auricles and ventricles must for long have been destroyed, but in which, nevertheless, the His-Purkinje system beyond the point of destruction showed no degeneration. They conclude from this that *conductivity* is not the *only* function of this system. Their paper was published after this lecture had been delivered and we thus see an enlargement in conceptions of the *functions* of this tract already manifesting itself, although we are no nearer a solution of the essential cause of these functions.

Jonesco, a surgeon of Bucharest, affirmed in 1897 that he had removed the entire chain of three sympathetic cervical ganglia with the intervening cord on both sides without ill result in a case of exophthalmic goitre, and, moreover, that he had never seen any evil consequences from this procedure. Some Parisian surgeons also report that they have cut the cord and removed the ganglia without a fatal result as a rule, although in one case, under the care of M. Faure, the patient suddenly died while under an anæsthetic after the cord and superior and inferior ganglia had been removed upon the right side. He suggests that the anæsthetic (chloroform) had a share in the catastrophe. The experience of able surgeons in this country, however, indicates that fatal consequences may be directly attributable to that severance of the connexion between the heart and its nervous endowment which continental surgeons affirm they have effected without such a result. I have the permission of my friend, Mr. C. B. Lockwood, conscious of his strength, for recording his unfortunate experience of such a case, with notes of which he has supplied me.

The patient, a young woman, aged 19 years, suffering from exophthalmic goitre, with thyroid, heart and eye signs of two years' duration, was admitted into St. Bartholomew's Hospital on Jan. 18th, 1899, under the care of Dr. W. P. Herringham. A month later (on Feb. 18th), the patient having been anæsthetised with gas and ether, Mr. Lockwood operated upon the cervical sympathetic about 2 o'clock in the afternoon. The ganglia were not removed but the cervical cords were divided, that on the left completely, and a small portion excised; that on the right consisted of two cords, one of which was divided. The patient was removed to bed and quite recovered from the anæsthetic. The classical signs of division of the sympathetic were well marked on the left side, the pupil of the left eye being contracted and the left half of the face flushed and occasionally sweating freely. The pulse and respiration were accelerated and the temperature slightly raised from the commencement. The pulse became irregular and occasionally intermitted. As the day advanced these signs were more marked. The pupils also varied in size and at 11.20 P.M. they were equal and "pin-point." At 1.15 A.M. on the 19th the temperature was 105·2° F., the respirations were 60, and the pulse was 200. At 2.42 A.M. there were general convulsions. Both pupils were dilated and the left more than the right. At 2.45 A.M. the patient died, the temperature being 105·6° and the left pupil being dilated and the right contracted.

A well-known provincial surgeon has also informed me that he divided the sympathetic cord on *one side only* and with fatal consequences in a case of exophthalmic goitre. It is difficult to reconcile these results with the experience of continental surgeons. Mr. Lockwood had *some difficulty* when operating on the chain in the right side of the neck in his case in determining in a leash of nerve cords which was the sympathetic, but the necropsy proved that he had completely divided the left and partially the right. Mr. F. F. Burghard of King's College Hospital informs me that he has on more than one occasion removed both the superior ganglia of the cervical sympathetic without fatal consequences, which is valuable clinical confirmation of the physiological conclusion from experiment that the chief cardiac outflow of visceral sympathetic nerves is through the inferior cervical ganglia without its previously traversing the superior ganglia.

Without wishing to be unduly sceptical one feels disposed to question whether there has not been some error as to complete division of the sympathetic in the cases reported to have suffered little inconvenience from the procedure. That an important nerve such as the pneumogastric may occasionally be divided on *one* side without fatal results is admitted, and the same is probably true of the sympathetic, but a complete division of the nerve on both sides, both as regards the pneumogastric and the sympathetic when the inferior cervical ganglion is involved, must on physiological grounds be scarcely compatible with life. Whatever view, therefore, may be taken of the essential nature of muscular and nervous action, it is manifest that their relation is so intimate in man as to render impossible *persistent* organic action when their union is severed, and we return to the position at which we commenced—namely, the tripartite unity of the hæmic, muscular, and nervous factors in cardiac action, which I imagine we all acknowledge to be essential to sustained organic activity.

So far, we have been concerned with a consideration of the essential or intrinsic causes of cardiac motion and therefore also with the causes of disorder in such function. Some reference may now be made to more accidental or extrinsic causes, for these also have an important bearing on treatment and, like all extrinsic or accidental circumstances, are at times more easy of correction than the essential causes of disordered cardiac action. Such extrinsic causes are mechanical and in their management frequently require the coöperation of the physician with the *surgeon*. They concern the blood-weight or distribution as distinct from the blood-supply to the cardiac muscle, the valvular mechanism to secure a due distribution of the blood, and space enough without impediment for the organ to contract and dilate and to receive and project its contents—in short, the causes which affect the working of the heart as distinct from those which underlie its action. The mechanical factors frequently dominate the situation, when, as so frequently happens, in addition to cardiac and intracardiac causes of difficult circulation, the movements of the organ are rendered more difficult by extracardiac adhesions to neighbouring parts, or by notable impediments to full respiration due to effusions of fluid or the presence of abnormal solids in the thoracic or abdominal cavities. The modification or, when possible, the removal of such aggravating mechanical factors then becomes a paramount necessity. It is manifest therefore that when the physician fails to restore an easy balance between the intrinsic factors in a labouring circulation by the indirect influence of the potent agents so frequently successful in his hands he *must* seek in some cases the coöperation of the surgeon in the modification or removal of such extrinsic factors as are amenable to his art.

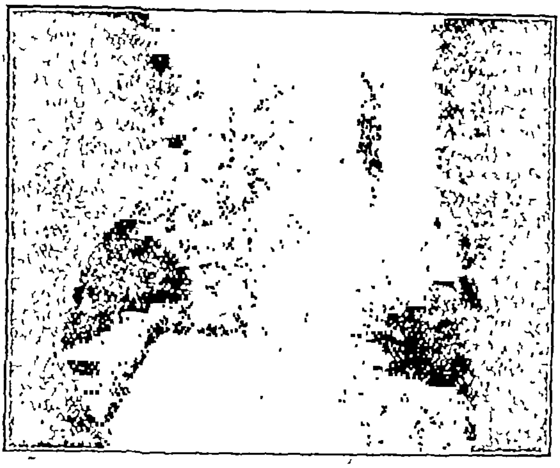
ON THE TREATMENT OF FRACTURES IN THE VICINITY OF JOINTS.

BY W. ARBUTHNOT LANE, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO GUY'S HOSPITAL AND SENIOR SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON, W.C.

I DO not propose to say anything about the diagnosis of fractures, since it has resolved itself so largely into a question of obtaining perfect x ray photographs. I will satisfy myself by urging the importance of obtaining photographs in several planes, since it is only in this way that the nature of the fracture can be accurately diagnosed. The x ray photograph also furnishes us with a ready means of determining the manner in which we have done our work, whether we have attempted to replace the fragments in accurate apposition by manipulation or by operation. In either case the part should immediately after the operation be photographed in several planes, so that any defect may be effectually dealt with as soon as possible.

The fractures about the ankle-joint come under two distinct groups. First we have those produced by excessive abduction, which are called Pott's fractures and which consist in a spiral or torsion fracture of the lower portion of the fibula with or without rupture of the internal lateral ligament, or of transverse fracture of a portion of the internal malleolus with or without a vertical fracture of the *posterior* and *outer* part of the lower end of the tibia which is attached by ligament to the fibula. Secondly we have those produced by a fall on the foot in a position of considerable adduction or of activity. In these the inner malleolus with a portion of the tibia are broken off by a vertical fracture which usually traverses the tibia at the junction of the malleolus with the lower surface of the tibia. The malleolus with the portion of the shaft is displaced upwards upon the rest of the tibia. The fibula is broken transversely immediately above the attachment to the lower end of the tibia. The fracture is of the nature of a scrunch and the fragments may be much comminuted. Fig. 1 represents such a fracture taken from *before backwards*. This man to avoid being crushed jumped down into a ship's hold. The inner malleolus with a portion of the tibia was displaced upwards, while the fibular fracture was much comminuted. The tibial fragment was replaced in position and was retained by means of a steel plate fixed by two screws, a long one traversing the lower end of the tibia and a short one the inner malleolus. It did not appear necessary to do anything to the fracture of the fibula. Fig. 2 shows the condition of the part after recovery.

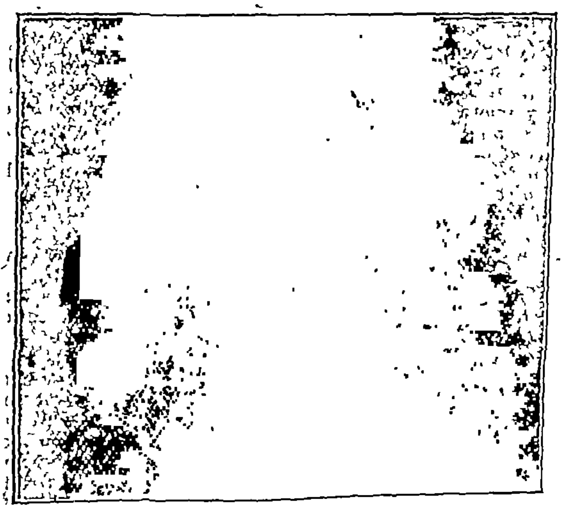
FIG. 1.



Represents an "adduction fracture" of the ankle taken from before backwards. It shows the character of the fracture of the fibula in this form of injury in a typical manner. It also illustrates very well the fact that a radiogram taken in this plane does not show the very considerable backward and upward displacement of the tibial fragment which almost always exists and which was most marked in this particular case. The omission to take radiograms of fractures of the ankle in two planes crossing each other at right angles has, in my experience, frequently led to disastrous results. The skiagram is taken at an angle which does not show the really great displacement which existed.

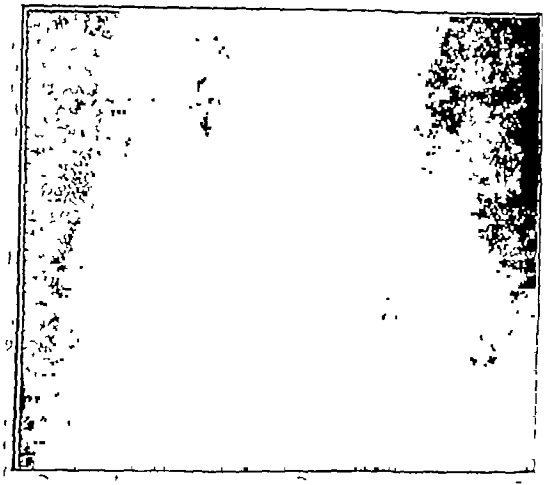
Now in either of the above conditions if by any process of manipulation and fixation in splints I am able to retain the fragments in apposition I am satisfied to deal with them in that manner. In a very alcoholic patient or in a fat woman I prefer to deal with them in this way even if I cannot effect anything approaching perfect apposition, for the reason that the lower end of the tibia and fibula in such people is very friable, the compact tissue being very thin. This produces a comminution or scrunching of the fragments, rendering accurate apposition by operation difficult or impossible because of the loss of substance. The retention of the *fragments in position* often cannot be effected, whether *screws, wires, plates, or staples* are used their h upon the bone is insufficient to be of any service.

FIG. 2.



Shows the condition of the parts after the patient had resumed his usual habits of life. The steel plate is seen lying on the inner aspect of the malleolus and shaft of the tibia, to both of which it is securely fixed by screws of suitable lengths.

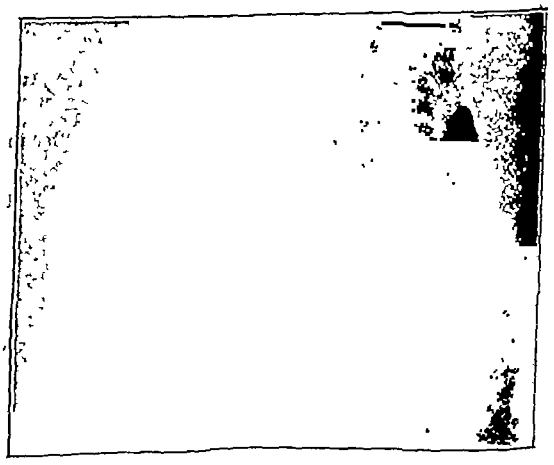
FIG. 3.



Represents an "adduction fracture" of the ankle in which the *tibial fragment* was secured by means of a single long screw. As in Fig. 2 the external malleolus is restored to its normal relationship to the astragalus, its fracture requiring no further operative treatment for its fixation.

In the ordinary subject, when I am able to satisfy mysel that apposition cannot be effected by manipulation, I do no hesitate to advise operative interference. How cases in eac of these two groups must be treated by operation depends largely on the details of the injury. Roughly speaking, in an abduction or Pott's fracture, since in these circumstances th fracture in the fibula is almost always clean and the textur *of the bone firm, I prefer to expose it and to unite* the frag ments in perfect apposition by silver wire perforating th fragments, by metal plates with screws, with screws alone and very occasionally with staples. Very frequently find combination of these methods very useful; for instance, the fragments may be perforated and a wire introduced which will include in its grip a plate through which screws are driven into the malleolus and into the fibula above the fracture. In this way not only are the *surfaces retained* in apposition

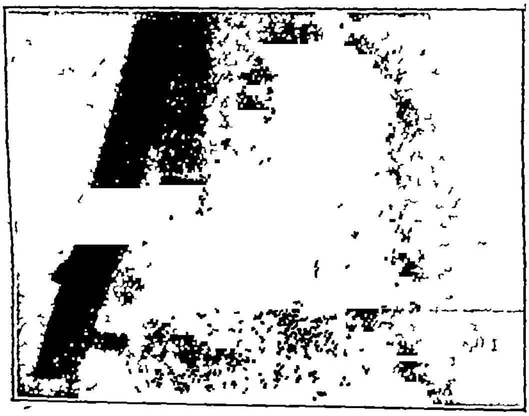
FIG. 4.



Represents an "abduction fracture," or Pott's fracture, of the ankle in which the displaced fibular fragment had after replacement in position been secured immoveably by a plate and screws.

by means of the encircling wire but a very stout steel splint is supplied, which takes almost all the strain off the junction and absolutely prevents any buckling of the fragments on one another. On effecting accurate apposition of the fibular fragments it is usually found that in the fracture of the back of the tibia and in that of the internal malleolus, should either or both exist, these fragments come into their normal position, but should the internal malleolus appear to be at all mobile I cut down on it and fasten it with wire, plate and screws, staple, or by a long screw perforating the inner malleolus and shaft obliquely in an outward and upward direction. Fig. 3 shows the manner in which the inner malleolus may sometimes be fixed with the greatest advantage by means of a single screw, the fibular fragments coming into accurate apposition. Fig. 4 represents a Pott's fracture in which the inner malleolus was not broken. The fibular fragments were secured in perfect apposition by means of a steel plate and screws. Fig. 5 is the result of an operation for a very bad Pott's fracture, accompanied by very considerable displacement of the foot and by a fracture of the internal malleolus and back of the tibia. The tibial fractures are not well shown in this illustration, the fragments having been replaced in accurate apposition. The fibular junction has been secured by a steel plate, two screws, and an encircling wire.

FIG. 5.



Represents the result of a bad case of abduction fracture in which the inner malleolus and the fibula were broken with a large piece of the back and outer part of the lower end of the tibia. The dislocation and replacement of fragments were effected with great difficulty A long steel plate with screws at either end, assisted by a stout silver wire, which encircled the seat of fracture and the plate, afforded a means of effecting securely the apposition of all the fragments.

The knee-joint, except for fracture of the patella, which calls for no special remarks, rarely sustains fracture of the ends of the femur or tibia. In separation of the epiphysis of the femur I have found it necessary to expose the seat of fracture in order to replace the fragments in position. As a rule there is little tendency to displacement, but if there is a couple of staples afford the most effective means of securing the surfaces in apposition. In vertical fractures into the joint I have found screws or wire efficient.

In fractures about the hip-joint, as in the shaft of the femur, long steel plates with several screws perforating both layers of compact tissue and placed at suitable angles have served best to retain the fragments in accurate apposition. Fig 6 represents a transverse fracture of the femur through the upper part of the lesser trochanter. There was some comminution of the upper fragment, a triangular fragment of bone being driven into the medulla. Every effort to replace the fragments by manipulation failed because of the displacement outwards and upwards of the upper fragment The fragments were exposed, the depressed piece of bone was levered into position, the broken surfaces were brought into accurate apposition and were retained securely in position by stout steel plates and screws. That the junction effected was secure was shown by the fact that though the man during the momentary absence of the nurse flung himself out of bed and subsequently developed delirium tremens, and though his splint had to be removed, nevertheless the fragments remained in accurate apposition, as is shown by Fig. 7, which was taken when the man left the hospital.

In extension and abduction fractures of the wrist, commonly called Colles's fractures, if the fragments cannot be replaced by manipulation I make a vertical incision over the posterior and outer aspect of the seat of fracture and introducing a steel elevator beneath the lower fragment, which may be formed by the epiphysis, lever it into position. This can only be done when the lower fragment is not comminuted. The hand is then fixed in a position of complete flexion and abduction. It is but rarely necessary to introduce any metal, since once placed accurately in position the fragment does not tend to become displaced.

FIG. 6.

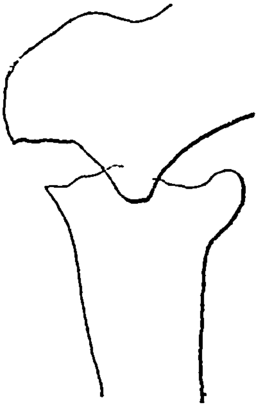


FIG. 7.

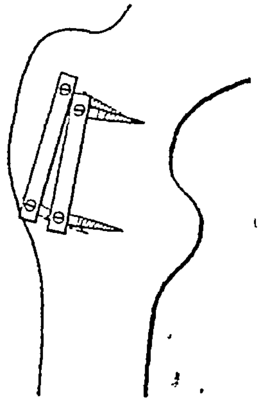

Fig 6 represents the tracing of a radiogram of a fracture of the femur about the level of the lesser trochanter, and Fig 7 shows a tracing after operation. These outlines were substituted for the original radiograms as these were not sufficiently clear for reproduction. The plates and screws which retained the fragments in position are also depicted.

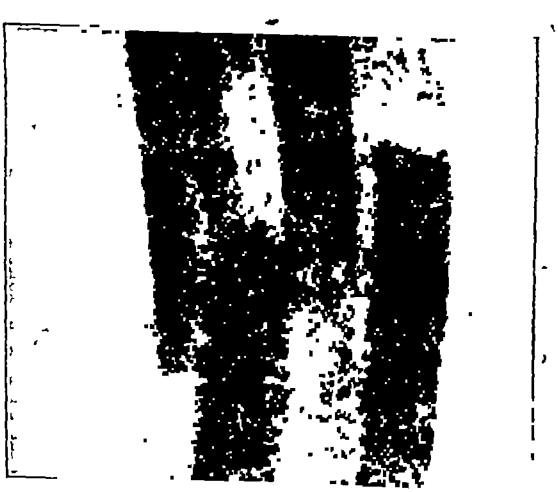
Fractures of the olecranon are, I believe, most effectually dealt with by means of a long screw Occasionally the screw may require removal after a long interval, because of the gradual exposure of its head. I have removed one 11 years after the operation for this reason Fractures of the coronoid process are sometimes very difficult to deal with. On the whole, I believe that excision of the fragment is generally the best treatment. Much depends, however, on the nature of the fracture and the displacement of the fragment.

FIG. 8.

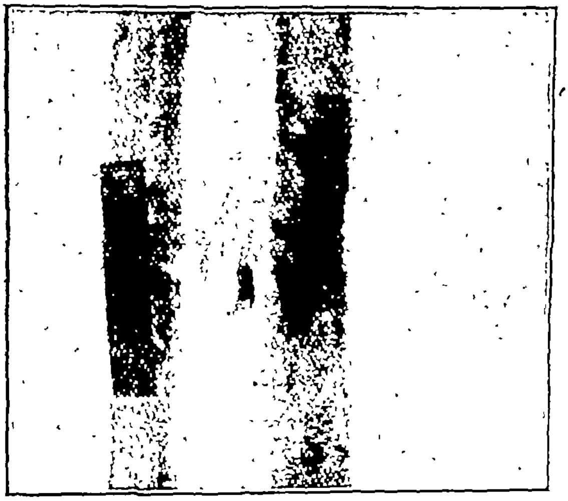


Represents an ununited fracture of the radius and ulna.

Fractures of the head of the radius are sometimes the cause of some anxiety as to the best measures that should be adopted. Sometimes I have replaced the fragment, fastening it in position. The difficulty I experienced was that owing to the small size of the fragment and its friability I was unable to fix it sufficiently firmly to permit of rotatory movements being commenced at once and while waiting for union adhesions were liable to form and limit movement. Again, in some cases I have removed the fragment and in others removed the stump of the head as well. In both very satisfactory results have ensued. If by manipulation the fragment can be restored to, or nearly to, its normal position passive movements undertaken at once form the best treatment.

The fracture about the elbow-joint that more frequently calls for operative treatment is that commonly called separation of the lower epiphysis of the humerus. In a small proportion of cases I have found it impossible to replace the epiphysis in perfect position by manipulation, but I have done it by making a vertical incision over the posterior aspect of the fracture, and by introducing a steel point between the fragments I have supplemented the leverage action exerted upon the fracture by the radius and ulna and so managed to restore the bone to its original form and usefulness. I have ceased to use any retaining media in these circumstances, since there is no tendency to displacement if the elbow is kept fully flexed. If the fragment is displaced laterally as well as backwards the lateral displacement must be reduced before that in an antero-posterior plane.

FIG. 9.

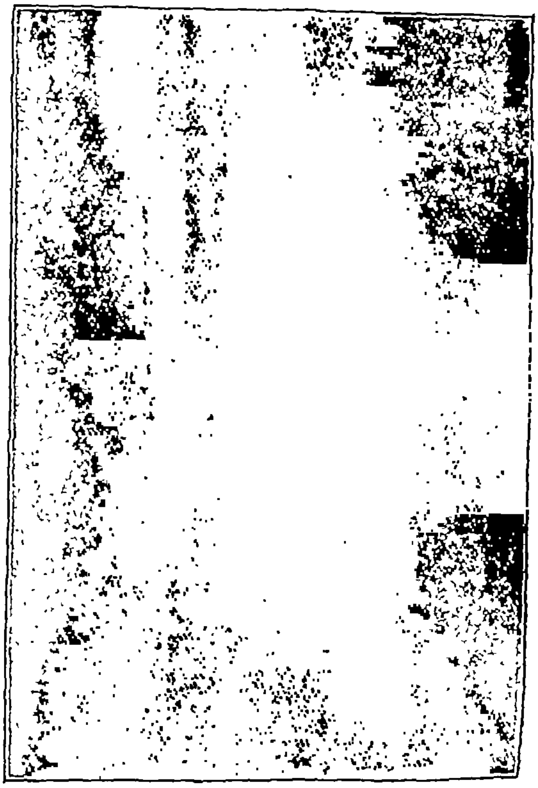


Shows the results of operation on Fig. 8, the replaced fragments having been secured by screws and plates.

The last joint to which I will call attention is the shoulder. In fractures of the upper end of the humerus in which I have been unable by manipulation to restore the bone to its original form and in which it was important that the functions of the joint should be perfect I have exposed the fracture and replaced the fragments in position. In many cases, as in separation of the epiphysis and in transverse fracture of the surgical neck, once accurate apposition has been obtained there is no tendency to displacement, but if the fracture is oblique or if the bones are comminuted some retaining medium must be employed. Staples are very useful when it is necessary to perforate the trochanters because of their cancellous structure, but if the fragments offer a dense hold screws or screws and plates are very useful. The results of such operations are as good as possible.

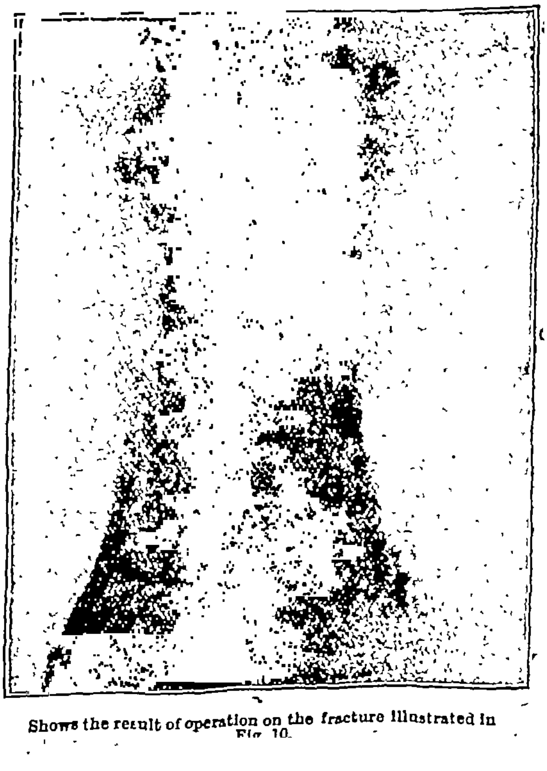
Now a few words as to the best media for retaining fragments in accurate apposition. I find screws in two gauges most useful; up to three-quarters of an inch Gauge 5 is as good as any. As three-quarters of an inch is a very useful size I use it in Gauge 7 also, which is the gauge of all the screws over that length. Having only two gauges three diamond drills only are required, one for the thread of the screw of Gauge 5, one for the barrel of Gauge 5 and for the thread of Gauge 7, and one for the barrel of Gauge 7. Stout metal plates can be usefully combined with the screws. They are made in various lengths with two, three, or more holes. Some of the plates are of steel, while others which are of

FIG. 10



Illustrates a comminuted fracture of the lower end of the femur in which the fragments were much displaced.

FIG. 11.



Shows the result of operation on the fracture illustrated in Fig. 10.

hard German silver can be best employed to fit the curves of bones. Those used for fractures of small bones like the radius, ulna, clavicle, and fibula are drilled to the 5 Gauge which allows the passage of a screw that will perforate both compact layers, a matter of vital importance since a screw obviously cannot get a secure hold on a single compact layer. To illustrate this I have chosen Fig. 8 which represents an ununited fracture of nearly three months' standing rather than a recent fracture, since the difficulties to be encountered are much greater in the former than in the latter. The injury was sustained on Feb. 22nd, 1906, and came under the care of a surgeon who has devoted much attention to the mode of production of fractures. I mention this fact to show that the patient had the advantage of the best treatment possible at the time of the injury. Manipulation was effected under an anæsthetic and plaster-of-Paris was employed for fixation. A useful arm was promised in about six weeks. On May 17th, we exposed the fragments, removed their ends, and effected accurate apposition by screws and plates. The patient has now a perfectly useful arm. Fig. 9 represents the fragments united by means of the plates and screws.

Fig. 10 represents a more or less vertical fracture of the lower end of the femur into the knee-joint in which the condyles were separated by a considerable interval. Fig. 11 shows the condition after operation.

Virgin silver appears to afford one of the best wire media should such be required. Staples with prominent or rounded angles are often very efficient in conditions suitable to their use, as in the case of the upper end of the humerus and the lower end of the femur. I know no condition in which pegs can be of any use mechanically.

Cavendish-square, W.

THE OPSONIC INDEX TO VARIOUS ORGANISMS IN THE SANE AND INSANE,

WITH THE RESULTS PRODUCED BY INJECTING TUBERCULIN.[1]

BY C. J. SHAW, M.D. EDIN., M.R.C.P. EDIN.,

ASSISTANT MEDICAL OFFICER, ROYAL ASYLUM, MONTROSE, N.B.

THE recent observations of Wright and others on the opsonic power of human blood serum to the tubercle bacillus and other organisms and the methods they have discovered of estimating this power have opened up a new field for research and provided new methods of treatment for bacterial diseases which have already produced beneficial results. As Wright[2] found that in cases of staphylococcal and tuberculous infection with an entire absence of clinical symptoms there was a diminished phagocytic power to these organisms as compared with that of healthy individuals, and as this power could be increased by injections of the corresponding vaccine, he concluded that the lowered phagocytic power permitted infection to occur and that the resistance to infection by any organism could be estimated by calculating the opsonic power of the blood serum. The results of observations recorded by Bulloch and others agree with those obtained by Wright and support his view, as all have found a lowered opsonic power in cases of localised tubercular and staphylococcal infection, and these are the cases which benefit most from vaccine injections. Low tuberculo-opsonic indices have also been found in cases of early phthisis "cured" by sanatorium treatment. These cases frequently relapse, however, and whether the low opsonic index is the cause or the result of infection is not definitely decided. The estimation of the opsonic index of a class of healthy patients with a decided liability to tuberculous infection is therefore an important point in estimating the value of a low index as an indication of the resistive power of the individual to infection.

The statistics of the death-rate from tubercular disease, particularly phthisis, occurring in asylums leave no room for doubt that the insane as a class are specially liable to tuberculous infection. In their last report the English Commissioners in Lunacy compare the death-rates in institutions for the insane with those of the general population, all deaths under the age of 15 years being excluded. The death-rate of the general population per 1000 from phthisis was for males 2·07 and for females 1·35, while in the insane population it was 16·0 and 14·6 for each sex respectively. The Scottish Commissioners in their report for 1905 refer to the same subject and quote figures which are equally striking. In the six district asylums showing the lowest death-rate from tuberculous disease, of which Perth district asylum is one, the average per 1000 patients resident was 11, while in the counties from which these asylums draw their patients the average per 1000 persons living between the ages of 20 and 60 years was 2·8. Clouston says that in asylums consumption is between three and four times more common than in the general population at the same ages, and the figures quoted above more than support his statement. Even although a certain amount of the difference in the death-rates might be accounted for by overcrowding or other unfavourable conditions in some asylums or by the greater number of post-mortem examinations, and more complete and accurate returns made by institutions, or by the great difference in the totals from which the averages are estimated, still the fact remains that the insane are more susceptible to tuberculosis than ordinary individuals.

I have made observations on the opsonic indices of six members of the staff of Perth District Asylum and also on 30 patients suffering from various forms of mental disease. All were at the time of observation free from active tuberculous disease but five of the patients examined showed evidences of having at one time suffered from such infection. Of these cases one had cicatrices in the neck, while the others showed signs of former lung mischief. Two of them were suffering from general paralysis, one of whom has since died, and only a few small cicatrices at the apex of one lung were found post mortem. The usual technique for the estimation of the opsonic index was employed, equal quantities of serum, leucocytes, and bacterial suspension being used. The blood for examination was taken at the same hour each day and five consecutive observations were made in each case. Koch's new tuberculin T.R. was then injected and daily observations were made for a further period. My own leucocytes were used throughout and my blood serum was used as control. Its opsonic power was fairly constant, the number of bacteria ingested showing little variation from day to day. For the estimation of the tuberculo-opsonic index the contents of 80 leucocytes were usually counted and in no case were less than 50 enumerated. Simultaneous observations were made on the opsonic power of various cases to the bacillus coli communis, staphylococcus aureus, and micrococcus rheumaticus. These observations were continued after the injection of tuberculin T.R. The contents of 50 leucocytes were usually counted for these observations, but on a few occasions only 30 were examined. The same number was examined in each case on the same day.

The average tuberculo-index of the six healthy control cases for five consecutive days was 1·07, the average for each case being 0·98, 0·97, 1·32, 1·06, 1·01, and 1·11, showing a variation between 0·97 and 1·32. This average index agrees with the results obtained by other observers in healthy persons. Urwick,[3] in 20 cases, found the average index to be 1·006, while Bulloch[4] in 84 cases found an index of 0·96, and in Lawson and Stewart's[5] 25 cases the average was 1. The total variation, 0·35, is less than that found by Bulloch in the 84 cases he examined. Urwick states that there is little variation in the index of a healthy person from day to day. I found considerable daily variation in some cases, though the observations were made as *far as* possible under the same conditions. The greatest amount of variation recorded between any two consecutive observations was 0·3. In one control case, however, a record so low as 0·68 was obtained on one occasion.

The average tuberculo-opsonic index of the 30 insane persons examined for five days was 0·88. The variation was between 0·65 and 1·23 *and the daily fluctuation* was greater than in the healthy control cases. Of these 30 cases the six with the highest indices gave an average of 1·07, which is exactly that found in the same number of control cases. Although a greater number of insane were examined it may be fairly concluded that the average tuberculo-opsonic index of the non-tubercular insane is below that of the healthy sane. The average of the five patients with evidences of old tubercular disease was the same as that found for all the 30 cases.

The difference between the index found in the control cases, 1·07, and that found in the insane patients, 0·88, is very marked. This observation is therefore strong evidence in favour of the view that the opsonic power of the blood serum can be used as a test of the liability to tuberculous infection.

An examination of the indices obtained in the various classes of patients gives corroborative evidence. The index obtained in four cases of general paralysis was 0·79. As a class general paralytics are peculiarly liable to tuberculous infection. Mickle states that of all such cases examined post mortem 26 per cent. exhibited caseation or cavities, 12 per cent. arrested phthisis, and 65 per cent. pleuritic adhesions. Two of the four cases observed showed evidence of old lung trouble, but the index of the two cases with no signs or symptoms of previous infection was only 0·78, so that their liability to tuberculous disease may be due to their low resistive power as indicated by the opsonic index. Seven of the patients examined were suffering from acute mental disease. Three of these were cases of adolescent insanity, a class of patient particularly liable to tuberculosis. Their average index was 0·84. Of the remaining four cases two suffered from melancholia and two from mania. The index of the former was 0·88, of the latter 0·91, and as patients suffering from maniacal excitement are less prone to contract tuberculous infection than those suffering from melancholia this observation also supports Wright's view.

The chronically insane are generally believed to be more liable to tuberculous infection than the more acute cases. In 11 chronic cases of secondary dementia the average index was 0·93, while that of seven acute cases was only 0·87. This would seem to indicate that the acutely insane have a lower resistive power than the chronic demented cases, but it is also possible that the latter may become infected during the period of acute onset of the mental disease.

To estimate still further if there was any difference between the sane and insane in their reaction to tubercle I injected the six control cases, all members of the asylum staff, and the 30 patients with Koch's new tuberculin T.R.

In estimating the effect of the injection of any drug or vaccine it is necessary to take into consideration the idiosyncrasy of the individual to the particular drug or vaccine used. With a vaccine injection the idiosyncrasy of the person injected may be taken to represent the liability to infection by the particular organism from which the vaccine is made. In persons suffering from bacterial infection the injection of a vaccine of the infecting organism is followed by a negative phase or fall in the opsonic power of the blood serum and if the dose used be large enough a temperature reaction and constitutional symptoms may be produced. The negative phase is followed by a rise in opsonic power, or positive phase, which lasts a variable time but ultimately the opsonic power falls back to the level at which it stood prior to injection.

Wright[6] has stated that the result of his observations seem to suggest that the development of a negative phase following a dose of T.R. smaller than that which would produce this result in a healthy person may prove to be an index of tubercular infection. He found that the negative phase supervenes upon a very much smaller dose and persists much longer in the case when the patient is the subject of extensive infection than in the contrary case. Lawson and Stewart[7] injected four healthy persons with tuberculin T.R., the dose not being stated, and produced no negative phase. They therefore concluded "that the appearance of a negative phase after inoculation with a small quantity of tuberculin T.R. should enable one to distinguish between the blood of a subject of tubercular invasion and that of a person in sound health." The production of a negative phase after injection is therefore very important from a diagnostic point of view. So far no exact definition of the term negative phase has been made. As I found considerable variation in the opsonic index from day to day and, especially in the insane, that a slight rise sometimes occurred at the first observation made 18 hours after injection, I take a negative phase to mean any fall in the opsonic index occurring within 48 hours after injection, the index being below the level noted at the time of injection and also below the average level for the five preceding days.

Four control cases were injected with $\frac{1}{500}$th of a milligramme of tuberculin T.R. In two a distinct negative phase resulted. The fall in both was immediate and lasted in the one case two days and in the other three days, reaching 0·59 and 0·63 respectively. The subsequent rise was rapid, reaching 1·57 in the first and 1·74 in the second case on the sixth day after injection, a point in both cases much higher than any previously reached. In the one case where there was a tuberculous family history the average index prior to inoculation was 0·98 and the amount of variation considerable. The injection was given at a point well above the average level. In the other the average index was 1·32, but was 1·28 on the day of injection. In the remaining two cases no negative phase was developed. Both were injected at a point below the average level and the succeeding indices were low. As the results obtained did not agree with those recorded by Lawson and Stewart I concluded that the dose used was too large. The remaining two cases were therefore injected with $\frac{1}{1000}$th of a milligramme of tuberclin T.R. and with this dose no negative phase was produced. An immediate rise in opsonic power followed the injection, the maximum being reached at the first subsequent observation. The average index of these two cases was 1·01 and 1·11, and they rose to 1·25 and 1·38 respectively. Both were injected at a point slightly above their average level.

Twelve patients were injected with $\frac{1}{500}$th of a milligramme of tuberculin T.R. and in eleven of these a negative phase occurred. In four cases there was a slight initial rise after injection, followed however by a decided fall, which was complete in all four cases on the third day. In six of the cases a lower level was recorded than that reached in either of the two control cases in which a negative phase occurred. In only two of the insane patients did the maximum of the positive phase reach the level attained by the lower of the two control cases. As a rule, the positive reaction was slower and less pronounced in the insane than in the members of the staff, and also in the acute than in the more chronic cases of mental disease. There was no marked peculiarity in the reaction of two of the cases who showed evidence of old tuberculosis.

The marked difference in the percentage of negative phases following injection in the control cases and insane patients, the lower level reached during the negative phase, and the delayed and less pronounced positive phase in the latter class seem to indicate that the resistive power of the insane to tuberculous infection is less than that possessed by sane healthy individuals.

Eighteen patients received an injection of $\frac{1}{1000}$th of a milligramme of tuberculin T.R. and only four showed a negative phase—that is, 22·2 per cent., compared with 91 per cent. of those injected with $\frac{1}{500}$th of a milligramme of tuberculin T.R. As the average index before injection in those to whom the larger dose was administered was 0·87, while in those who received the smaller dose it was 0·89, the greater percentage of negative phases in the former class must be due to the larger quantity injected. All the patients injected with $\frac{1}{1000}$th of a milligramme of tuberculin T.R. were suffering from subacute or chronic mental disease, but the greater percentage of negative phases produced with the larger dose in both the control and insane cases indicates that $\frac{1}{500}$th of a milligramme of tuberculin T.R. is too large a dose to use for diagnostic purposes, and the high percentage following injection with $\frac{1}{1000}$th of a milligramme of tuberculin T.R. would seem to show that a still smaller dose ought to be employed. Only one of the four cases in whom a negative phase occurred—a general paralytic—showed evidences of old infection. The average index of the four prior to injection was 0·99, but the daily variation in these cases was greater than in the 14 in whom no such reaction was produced.

The chief difference noted between the two control cases and the 14 insane patients in whom no negative phase followed inoculation with $\frac{1}{1000}$th of a milligramme of tuberculin T.R. was the slower reaction of the latter after injection. Both control cases reached their maximum on the day following injection, while the insane took an average of four days to reach their positive maximum, but there was little difference in the level ultimately reached, though the average index before injection was lower in the insane.

Wright[8] has shown that a fresh injection of tuberculin during the negative phase produced by a previous injection emphasises the negative phase. I have been unable to trace any connexion between the level of the tuberculo-opsonic index on the day of injection and the subsequent presence or absence of a negative phase. It would appear that in non-tuberculous persons the amount injected has a more important bearing on the result produced than the level of the opsonic index on the day of injection. In all cases where a negative phase was recorded there had been greater irregularity in the opsonic power from day to day previous to injection than in those cases where no such result was observed.

Observations on the opsonic indices to other organisms.—The opsonic power of the serum of five control cases and a number of insane patients was estimated to the bacillus coli communis, staphylococcus aureus, and micrococcus rheumaticus, as well as to the tubercle bacillus. Johnstone and Goodall[9] found agglutinins to various strains of the bacillus colic communis in the blood of 60 per cent. of insane cases examined by them. This form of infection is common in such patients and in cases of cystitis in the asylum I have found this, or an allied organism, present in the urine. Boils and skin irritations are common amongst the insane and a staphylococcus aureus may be isolated from many such cases. The strain used during these observations was obtained from the bone marrow of a case of acute mania who died in a typhoid condition. Rheumatism in its various forms is possibly the most common ailment in the district from which the patients were drawn and although this disease does not appear to be more common in the asylum than in the surrounding district I used the micrococcus rheumaticus as a third type of common infective agents.

So far as could be ascertained none of the individuals examined were suffering from any form of illness while under examination and all carious teeth and other sources of infection were removed before any observations were made.

In the control cases the tuberculo-opsonic index was 1·08. To bacillus coli the average index for five days was 1·02, to staphylococcus aureus 1·1, and to micrococcus rheumaticus 1·07. There would therefore appear to be little difference in the average index of healthy individuals to these various organisms. The amount of variation between the average indices of each individual to the separate organisms was greatest to staphylococcus aureus and least to bacillus coli.

To bacillus coli the average index of 12 patients was 1·06. This result compares favourably with that found in the control cases but the amount of variation was greater. The tuberculo-opsonic index of the same patients was 0·97. In 15 cases tested to staphylococcus aureus the index was 1·07. In the same cases the average tuberculo-opsonic index was only 0·9. 11 cases were observed to micrococcus rheumaticus; the index obtained to this organism was 0·94, while to tubercle in the same cases it was 0·91. There is therefore little difference between the average index of the control and insane cases to these three organisms.

With the exception of bacillus coli the average opsonic index of the control cases was higher to all the organisms employed than that of the insane. The amount of variation was less in the control cases except to staphylococcus aureus. The tuberculo-opsonic index of the insane is lower than the index found to any of the other organisms in the same series of cases and the amount of variations to tubercle is greater. These observations would indicate that the insane are more liable to organismal infection than the sane, and that they have a lower resistive power to tubercle than to any other of the organisms employed.

All four control cases injected with $\frac{1}{500}$th of a milligramme of tuberculin T.R. showed a subsequent negative phase to staphylococcus aureus. Three gave a similar reaction to bacillus coli and two to micrococcus rheumaticus. Of the two cases who gave no negative phase to tubercle, one had a fall in opsonic power to all three organisms, while the other gave a similar result with bacillus coli and staphylococcus aureus. Two of these cases developed a negative phase to tubercle. One of them reacted in the same way to all the three organisms, while the other only did so to staphylococcus aureus. Of the 12 series of observations made to organisms other than the tubercle bacillus after the injection of tuberculin, in nine a negative phase resulted, that is in 75 per cent. The fifth control case was injected with $\frac{1}{750}$th of a milligramme of tuberculin T.R. No negative phase to tubercle was produced, but there was a fall in opsonic power to micrococcus rheumaticus.

Nine patients injected with $\frac{1}{500}$th of a milligramme of tuberculin T.R. were tested to bacillus coli after injection and in all a negative phase resulted. All 12 cases injected with this dose of tuberculin T.R. were tested to staphylococcus aureus and in eight a negative phase followed, that is in 66·6 per cent. Of eight cases examined to micrococcus rheumaticus, five gave a negative phase, that is 62·5 per cent. A series of 29 observations was made on the insane patients to the three organisms after injecting tuberculin and in 22 cases negative phases were produced, that is in 75·86 per cent. On comparing the results obtained in the control and insane cases to these organisms it is seen that as there was little difference in their average indices before injection so the total percentage of negative phases produced is very similar in the two classes. The percentage of cases where a negative phase was observed was less in the control than in the insane cases to bacillus coli and micrococcus rheumaticus, but greater in the control cases to staphylococcus aureus, and this was the only organism in which the variation in the indices before injection was greater in the control cases than in the insane.

Three patients were injected with $\frac{1}{750}$th of a milligramme of tuberculin T.R. and afterwards tested to the other organisms. One of them gave a negative phase to tubercle only. Two gave no negative phase to tubercle, but one of them showed this reaction to all the other organisms while the other did so to bacillus coli. Of the nine observations made to the organisms now under consideration four showed a negative phase, while in the one control case similarly tested after being injected with the same dose of tuberculin the only negative phase recorded was to micrococcus rheumaticus. There is therefore a larger proportion of negative phases produced in the insane with this dose also.

A comparison of the results obtained in the different classes of cases to all the organisms, before and after injecting tuberculin, shows that there is a difference in the resistive power to organismal invasion between them. The tuberculo-opsonic index of five control cases before injection was 1·08, to bacillus coli it was 1·02, to staphylococcus aureus 1·1, and to micrococcus rheumaticus 1·07, giving an aggregate average of 1·06. Of the cases of acute mental disease examined to two or more organisms the index to tubercle was 0·87, to bacillus coli 0·96, to staphylococcus aureus 1·01, and to micrococcus rheumaticus 0·9, the aggregate average being 0·93. The more chronic cases similarly examined showed an average index to tubercle of 0·93, to bacillus coli 1·05, to staphylococcus aureus 1·12, and to micrococcus rheumaticus 0·96, while the aggregate average was 1·01. The index recorded to each organism for the acute cases is therefore below that of the control cases and also of the more chronic patients. The index of the chronic cases is below that of the control cases to tubercle and micrococcus rheumaticus but slightly above the control index to bacillus coli and staphylococcus aureus, but the control aggregate is higher. As no acute case was injected with $\frac{1}{750}$th of a milligramme of tuberculin T.R. a comparison of the different results after injection can only be made on those who received $\frac{1}{500}$th of a milligramme of tuberculin T.R. With this dose the percentage of negative phases recorded in the control cases to all the organisms was 68·7. In the acute cases it was 80·9 and in the chronic cases 80. The percentage is seen to be highest in the acute cases and lowest in the control cases. This result corresponds with that obtained by comparing the average indices before injection and would seem to show that the resistive power of the insane to organismal infection is less than that possessed by the sane and that the more chronic are less liable to infection than the more acute cases.

Five chronic cases tested to all four organisms were injected with $\frac{1}{500}$th of a milligramme of tuberculin T.R. and a negative phase resulted in 80 per cent. Three similar cases received an injection of $\frac{1}{750}$th of a milligramme of tuberculin T.R., and in 41·6 per cent. of the subsequent observations a negative phase was noted. A very slight reduction of the dose injected has therefore a marked effect on the number of negative phases produced.

The demonstration of the specificity of the opsonic body in the blood serum is necessary to support the view that the production of a negative phase after the injection of a minute dose of tuberculin is diagnostic of infection by the tubercle bacillus. Bulloch has shown by experiments that the opsonic body is largely specific. I found that with a dose of $\frac{1}{500}$th of a milligramme of tuberculin T.R. even in absolutely healthy individuals a fall of opsonic power to other organisms than the tubercle bacillus was produced. In one control case injected with $\frac{1}{100}$th of a milligramme of tuberculin T.R., though there was a rise in opsonic power to tubercle, there was a fall to the micrococcus rheumaticus after injection. Both these doses are therefore too large for diagnostic purposes.

---

[9] Brit. Med. Jour., Oct. 3rd, 1903.

The absence of local and constitutional symptoms after the injection of tuberculin was very marked. There was no local irritation and beyond a slight feeling of stiffness in the flank at the site of inoculation no inconvenience was caused, and all continued to perform their usual duties. In two control cases there was a slight increase of pulse-rate. In one it was 92 per minute on the evening after injection, while in the other it was 102 on the second evening. There was no rise of temperature, however.

The temperature chart of the insane frequently shows greater irregularity than that of healthy individuals, but the temperature and pulse-rate of the patients injected with $\frac{1}{500}$th of a milligramme of tuberculin T.R. showed no greater variation after injection than had occurred in the same cases during the preceding week.

In all 20 persons were injected with $\frac{1}{100}$th of a milligramme of tuberculin T.R. and in only three did any alteration in temperature or pulse-rate occur. Two were general paralytics. In one the temperature recorded on the second day was 99° F., while in the other the pulse-rate was 94, but the temperature was not affected, and though this patient showed evidences of old lung disease no negative phase was recorded. Such changes in temperature and pulse-rate frequently occur in general paralytics and were therefore not necessarily due to the administration of tuberculin. In the third case the temperature rose to 99·2° on the evening after injection. Such doses of tuberculin T.R. can therefore be administered to non-tuberculous persons with perfect safety.

No mental effect was produced by $\frac{1}{100}$th of a milligramme of tuberculin T.R. and though all the acute cases were inoculated with the larger dose the mental symptoms resulting were neither definite nor lasting.

Conclusions.—Some important general conclusions may be drawn from the results obtained. 1. As the insane are particularly liable to tuberculous infection a comparison of the average indices recorded in the sane and insane and also in the various classes of insane patients would indicate that the opsonic power of the blood serum can be used as a measure of liability to infection and that a low opsonic index precedes infection. 2. The injection of a small dose of tuberculin T.R. in healthy persons produces no negative phase to the tubercle bacillus and therefore may be used as a method of diagnosis. A smaller dose of tuberculin will, however, produce a negative phase in a predisposed person than in one less liable to tuberculous infection. 3. To determine the value of a negative phase after injection the daily variation in opsonic power as well as its level at the time of injection must be estimated. For this reason a number of consecutive observations are necessary; a single, or a number of isolated observations is not sufficient. 4. The average opsonic indices of healthy individuals varies little to different organisms. 5. The injection of a large dose of tuberculin even in healthy individuals causes a fall in opsonic power to other organisms than the tubercle bacillus. This explains the liability of tuberculous cases to secondary infection. For purposes of differential diagnosis by the production of a negative phase a very small dose must be administered. 6. Large doses of tuberculin can be injected into healthy persons without producing constitutional symptoms. Amount of dose may therefore be a matter of diagnostic significance as a small dose causes a reaction in infected cases.

I am greatly indebted to the members of the asylum staff and especially to Dr. L O. Bruce, the medical superintendent of the Perth District Asylum, for the encouragment and facilities afforded me while engaged in this work.

Montrose.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.—The festival dinner in aid of the funds of the above hospital will be held on Tuesday, June 4th, at the Trocadéro Restaurant, Piccadilly Circus, W., at 7.30 P.M. The Right Honourable the Lord Mayor of London will preside.

ON THE CLINICAL ASPECTS OF METASTASES TO THE CENTRAL NERVOUS SYSTEM AND OTHER PARTS IN MALIGNANT DISEASE OF THE VISCERA.

BY C. O. HAWTHORNE, M.D. GLASG., M.R.C.P. LOND.,
EXAMINER IN MEDICINE AND CLINICAL MEDICINE IN THE UNIVERSIT
OF ABERDEEN; PHYSICIAN TO THE CENTRAL LONDON
OPHTHALMIC HOSPITAL; ASSISTANT PHYSICIAN TO
THE NORTH-WEST LONDON AND ROYAL
WATERLOO HOSPITALS.

IN one of his articles on "The Medical Aspects of Carcinoma of the Breast" Professor W. Osler states that "in many cases of internal metastases in cancer of the breast th symptoms are obscure or there are features which make th diagnosis doubtful." In illustration of this general proposition Professor Osler quotes a number of case records whicl show that the clinical difficulties created by such metastase arise from a variety of causes. In some cases the primar growth in the breast fails, on account of its small size, t attract attention, or it possesses features which conceal it true nature. In others, though the breast tumour has bee recognised and removed, so long an interval has elapse before the clinical evidences of internal metastases displa themselves, that their real significance and relationship ar overlooked. And in a third group, while one or other o the positions just defined may also exist, the symptom caused by the metastases are so purely subjective that a interpretation of them as merely functional disturbances i readily adopted. This last-mentioned position seems to b reached in connexion more particularly with the development of secondary malignant tumours in the spinal canal and situated so as to involve either the spinal cord itself or the posterior roots of the spinal nerves. Pains in the back and side, often indefinite and ill-defined as to position, and sometimes becoming of agonising severity, "may persist for months," says Professor Osler, "without any sign of organic disease"; and even throughout the course of the illness—a period possibly of two years, or even longer—there may be no disturbance of either motion or sensation. In short, the diagnosis of metastases secondary to carcinoma of the breast may be missed, from non-recognition of the original tumour, from delay in the occurrence of the metastases, or from restriction of the clinical evidences to the subjective sensations of the patient.

It is now proposed to describe briefly some clinical experiences which show that what is true, as stated above, of carcinoma of the breast and its secondary developments applies equally to carcinoma of the viscera and the metastases which may result therefrom. In one direction, at least so far as the non-recognition of the primary growth is concerned, this statement has no unfamiliar sound. Thus it needs but a moderate acquaintance with the facts of clinical medicine to learn of cases of secondary cancer of the liver in which neither the history nor the physical examination gives any hint of the site, or indeed of the existence, of a primary malignant process. It happens that the clinical facts and associations of the secondary growths in such cases are often very conspicuous and free from ambiguity. Further, experiences of this order are relatively frequent events. Hence, here, not only are the results of the metastatic process usually recognised easily but custom removes the surprise which might otherwise be expressed at the absence of all evidences of a primary tumour. It is not unimportant to illustrate the proposition that a very similar order of events may be noted when the primary disease takes origin in organs other than the alimentary canal—such, for example, as the lung, the pleura, or the bladder—and when the secondary growths appear not in the liver but in the central nervous system, the bones, or other parts. Primary malignant disease of the lung or bladder, as is shown in cases recorded in this article, is by no means always in its clinical aspect an urgent and distinctive process, and the symptoms resulting therefrom may fail altogether to suggest the serious conditions on which they, as a matter of fact, depend. Hence secondary or metastatic developments in such cases may readily fail to secure an accurate and ready interpretation, and if, as may be the case, the symptoms arising from such developments are entirely subjective in character, it is hardly surprising to find that they are apt to receive something less than clinical justice. The moral obviously is that with evidences of visceral disease of more or less obscure significance, and possibly, therefore, indicative of a malignant growth, subsequent disturbances, even though remote in time and situation and wanting in precision, should be regarded with active suspicion. Pain, particularly if severe, obstinate, or recurring, or referred to the back, or to the course of one or more of the spinal nerves, cannot, in such circumstances, be safely dismissed as hysterical or neurotic because of its freedom from association with objective signs of organic disease; the event may pass a painful commentary on such a conclusion. The only safe course is to suspend judgment, with a leaning, perhaps, to the more serious view, until either the appearance of conclusive evidence on the one hand, or the lapse of time without any such demonstration on the other, places the issue beyond dispute. Certain it is that definite proof of metastases subsequent to primary malignant disease of the viscera, at least when the nervous system is the part secondarily involved, may not be obtained until very shortly before the patient's death, and it is conceivable that such proof may even never appear. In the first two of the following cases the primary malignant process, in one case in the lung, in the other in the bladder, gave rise to a mere minimum of local disturbance and to no admitted invasion of the general health and strength, and the patients were comparatively young women. There was thus in each instance little or nothing to excite active suspicion of the true nature of the primary visceral disease. Hence, when nervous symptoms appeared as a result of metastatic extensions their relationship to the earlier symptoms of visceral disease was not easily suggested and there was a temptation to suppose that the sequence was a purely accidental one. Further, the nervous symptoms were comparatively long in existence before objective demonstration of their association with organic change could be obtained. These two cases, therefore, illustrate the propositions which have already been stated. In a third case, whilst there was no doubt about the nature or the site of the original disease, the visual disturbance (hemianopsia) affords an interesting illustration of one among the many possible results of malignant metastases to the central nervous system. A fourth case is added to show how metastases to the bones may bear on the diagnosis of malignant disease of the viscera, the lung in this particular instance being the organ primarily involved.

CASE 1. *Malignant disease of the lung without active symptoms; later, severe pains in the lower limbs; evidence of intracranial disease a few days before death.*—The patient was a woman, aged 37 years, for whose earlier history I am indebted to Mr. Ernest W. Cross. With the exception of an ovarian cyst, which was removed by operation in 1902, the patient was free from serious illness until July, 1905; she then had an attack of pleurisy at the left base. The pyrexia and friction disappeared in the course of a few days, but some intra-pulmonary crepitations were detected, and later there were physical signs of a moderate amount of pleural effusion. In November she was admitted to the Royal National Hospital for Consumption at Ventnor, where she improved generally, and the evidences of pleural effusion diminished. There was no expectoration and thus no search could be made for the bacillus of tubercle. Shortly prior to her admission to the hospital at Ventnor she had complained of pains in the lower extremities, and these became increasingly severe in the latter part of November, often then preventing sleep and demanding the use of morphine. When seen on Dec. 18th the patient appeared to be a well-nourished woman, and her sole complaint was of pain in her lower limbs; the chest condition gave her no trouble. Nevertheless, there were signs of consolidation at the left base and some moist râles were present during inspiration. On physical examination no explanation of the pains could be detected, all the usual clinical tests of the condition of the nervous system giving normal results. On the 21st the patient was admitted to the Royal Waterloo Hospital, and in the course of a day or two it was observed that her speech had a slurred quality and that her mental condition was not clear. Soon she became noisy and semi-delirious and it was then found that double optic neuritis had developed. There were no other evidences of organic nervous disease and the temperature was normal or subfebrile. Afterwards the patient became comatose and died on Jan. 8th, 1906.

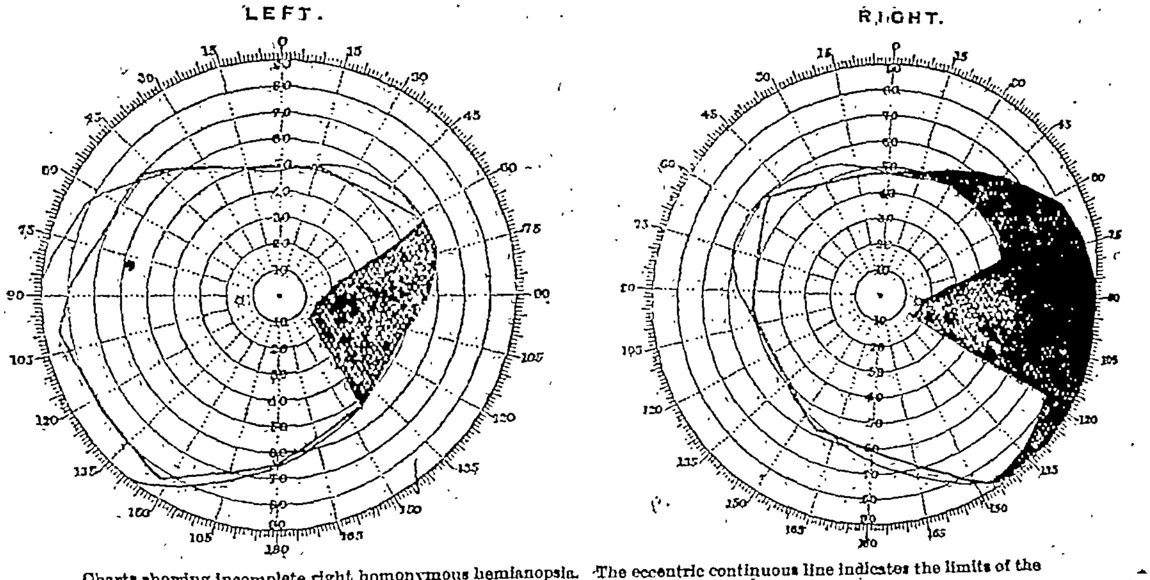
The post-mortem examination showed malignant disease (carcinoma) involving the lower third or so of the left lung and some scattered malignant nodules in the liver. Of chief interest, perhaps, was the condition of the brain. Here, in the soft membranes over the convexity of the hemispheres, were several localised hæmorrhages. The largest, having a diameter of about one inch, was situated immediately behind the upper part of the right Rolandic fissure; superficially it had a pale jelly-like appearance and deeply it passed into the sulci and to a slight extent had torn its way into the brain tissue. A smaller hæmorrhage was present about the middle of the left parietal lobe and several others were scattered over the convolutions. With these exceptions the brain appeared to be normal; the spinal cord unfortunately could not be examined. There can, however, be no doubt that either the cord itself or the posterior nerve roots were directly disturbed by a secondary malignant process and that in this way are to be explained the severe pains which formed the prominent feature of the case. Hence it is of great interest to note that at no time, and in spite of repeated examinations, were there discovered any abnormal conditions of the tendon jerks or other objective facts suggestive of organic disease of the cord. The pain was the one and only piece of clinical evidence of the existence of organic change of a malignant order in the lower part of the central nervous system. And it was not until a very few days before death that a demonstration of organic disease in any part of the nervous system could be obtained. Of great interest, too, is the development of optic neuritis in relation to the actual intracranial lesion demonstrated at the necropsy. There were no meningitis and no tumour, at least in the ordinary sense of the term. Yet it may be held that the blood-clot on the surface of the cortex was the physical equivalent of a tumour and that it must bear responsibility as the cause of the neuritis. The only alternative, as an explanation of the neuritis, seems to be embolism of the central artery of each retina. Bilateral retinal embolism is not an easy diagnosis to accept, and, moreover, the ophthalmoscopic picture was the one familiar in optic neuritis and in no respect resembled that of embolism. Thus it seems certain that a blood-clot of moderate size and situated over the cerebral convolutions may cause optic neuritis, and presumably by the same mechanism, whatever that may be, as the one by which intracranial tumour establishes this result. Indeed, a blood-clot in such circumstances may come under the definition (Hughlings Jackson) of tumour as a "foreign body or adventitious product" within the skull. But if this is true of a clot outside the blood-vessels it is conceivable that the same conclusion may apply to an intravascular clot situated in the cerebral veins or sinuses. Both in the one case and the other the bulk of the cranial contents is presumably increased. And as it has been suggested that the optic neuritis which occasionally occurs in chlorosis is to be explained as the result of sinus or venous thrombosis, the present case may be quoted as lending some support to this doctrine. Hence, in addition to the illustration which the case affords of the at times quiescent character of malignant disease of the lung, and of the clinical obscurity which often attends secondary malignant developments in the central nervous system, the record is not without relationship to the problem presented by the occurrence of optic neuritis in circumstances where there is reason to disbelieve in the existence of gross intracranial disease.

In the case next following double optic neuritis is found in association with a tumour situated in the cerebral cortex and it will hardly be questioned that the relationship of these two facts is that of cause and effect. The only difference between the two cases, in this respect, is that in the one first related the "foreign body or adventitious product" in the cortex is a blood-clot and not a neoplasm. To regard this clot as the cause of the optic neuritis, therefore, seems inevitable, and granted this, it is no large step to the proposition that a clot situated elsewhere within the skull (for example, in one or other of the intracranial sinuses) may also conceivably produce optic neuritis.

CASE 2. *Metastases to brain secondary to carcinoma of the bladder; occasional hæmaturia the only symptom of the primary disease; headache of some months' duration and followed by ocular paralysis and double optic neuritis.*—The patient, a woman, aged 39 years, came to hospital complaining of pains in the head, "worse than an ordinary headache." The pains had troubled her for two or three months and recently had "caused" her to see double. The personal history was one of good general health, though in the course of the inquiry the patient stated that she had "for years" passed blood in the urine "every two months." Examination showed homonymous diplopia increasing to the right, though no manifest defect in the action of the right external rectus muscle could be appreciated; and the optic discs were regarded as "definitely suspicious." Otherwise there were no evidences of organic disease and in particular the urine contained neither albumin nor blood. The patient declined admission to the hospital but returned in a fortnight's time with obvious defect in the action of the external rectus of each eyeball and with marked double optic neuritis; the urine now contained blood, but no tube casts or other renal elements could be found. After admission to the ward headache and vomiting were troublesome symptoms, but beyond the ocular paralyses and the optic neuritis nothing further was discovered; and in the course of some ten days the patient became comatose and died. In view of the urgency of the cerebral symptoms no systematic attempt was made to examine the bladder, and the single fact of hæmaturia when taken together with the somewhat indefinite history of the bleeding contributed by the patient, caused this aspect of the case to receive less than its due share of attention. Yet at the post-mortem examination it was found that the cause of the hæmaturia—namely, a malignant ulcer at the fundus of the bladder—was the starting-point of the whole train of subsequent symptoms. For in the cortex of the parietal lobe of the left cerebral hemisphere was a considerable malignant tumour (carcinoma) and several small nodules of malignant growth were found scattered in the cortical substance of both hemispheres. There were no growths at the base of the brain and the paralysis of both sixth nerves must have been due to the general increase of the intracranial pressure consequent on the growths in the upper part of the cerebrum—an illustration of the familiar fact that a sixth nerve paralysis has little or no localising value. Some nodules of malignant tissue were found in each lung.

Here, as in the first case, the primary malignant disease caused little disturbance. Indeed, it was only when headache became troublesome that the patient thought it necessary to seek medical advice. Further, the headache had been in existence for two or three months before objective evidence of organic intracranial disease could be detected. And even then the connexion between the hæmaturia, on the one hand, and the cerebral symptoms on the other, was far from obvious. The case may thus be placed as a parallel to those instances of mammary cancer in which the primary tumour is not recognised and in which, therefore, the interpretation of symptoms arising as a result of metastases to other organs is rendered difficult or impossible.

CASE 3. *Malignant disease of the lower bowel followed by right homonymous hemianopsia.*—In this instance there was no uncertainty in the diagnosis of the primary growth, as the patient, a man aged 60 years, had been operated on for malignant disease of the lower bowel. Shortly after the operation he complained that he could not see to his right side and on taking his visual fields the charts as shown in the illustration were obtained. In view of the right homonymous hemianopsia it seems certain that the patient was the victim of secondary malignant disease in the hinder part of the left visual tract and the incompleteness of the visual defect suggests the left half vision centre in the occipital lobe as the probable site of the secondary lesion. There was, at the time the charts were taken, no optic neuritis or other sign of cerebral disease. Unfortunately, the patient could not be traced at a later date and thus the subsequent developments can only be surmised. Though the case seems free from diagnostic difficulties it is not without interest in the discussion of involvement of the nervous system secondary to malignant growths in the viscera of the chest and abdomen.



Charts showing incomplete right homonymous hemianopsia. The eccentric continuous line indicates the limits of the average normal field of vision.

CASE 4. *Malignant disease of lung; metastasis to femur.*—In the latter part of the paper already quoted Professor Osler refers to metastases to the bones secondary to cancer of the breast and here again the sequence may find its parallel in cases of malignant visceral disease. In a patient recently under observation, a man, aged 62 years, the diagnosis of malignant disease at the base of the left lung came to be doubted, if not by the medical attendants, at least by th patient's friends, in consequence of the cessation of all activ symptoms, and of some improvement in the patient's genera condition during a period extending over several month Somewhat suddenly, however, as the patient was walkin across his room, he became conscious of a severe pain in hi left hip and of inability to use the limb. There was grea tenderness over the neck of the femur but no actual tumou could be detected. The patient, however, never regaine power over his limb and, without much evidence of renewe activity in the diseased lung, gradually lost strength and died about three months after the above event. The absence of any definite tumour of the thigh cannot be regarded as sufficient to neutralise the presumption that the patient was the victim of a secondary malignant growth in the upper part of the femur and that to this the pain, tenderness, and helplessness of the limb must be directly credited. In this case the metastasis was an occurrence which, so far from confusing the diagnosis of malignant disease of the lung, strengthened that opinion at a time when the general condition of the patient appeared to bring the original view more or less definitely under suspicion.

References.—In addition to Professor Osler's articles (American Medicine, April, 1901, Brit. Med. Jour., Jan. 6th, 1906), and to the records quoted with these, recent interesting examples of malignant metastases to the brain and spinal cord have been reported by Spiller and Weisenburg (Journal of Nervous and Mental Disorders, August, 1898), and by Pinatelle and Cavaillon (quoted in Epitome, Brit. Med. Jour., July 14th, 1906. The following may also be consulted: Tumour in Wall of Heart Secondary to Cancer of Œsophagus, Travers Smith, Brit. Med. A CASE OF PARATYPHOID FEVER FOLLOWING THE REMOVAL OF AN OVARIAN CYST.

BY WILLIAM THYNE, M.A., M.D. EDIN.,
SURGEON TO THE VICTORIA COTTAGE HOSPITAL, BARNET; AND MEDICAL SUPERINTENDENT OF THE BARNET ISOLATION HOSPITAL.

A WOMAN, aged 38 years, was admitted to the Victoria Cottage Hospital, Barnet, on Dec. 30th, 1906. On Jan. 8th, 1907, assisted by Mr. W. H. Elam, I removed an ovarian cyst of about the size of a football with doubly twisted pedicle and omental adhesions. The patient appeared to make an excellent recovery until the 21st (23 days after admission), when her temperature began to rise, reaching 101° F. on the evening of the 23rd, and continuing between 100° and 101° until the 29th, when it reached 102°; her appetite became impaired and she had a feeling of indefinite illness. The temperature became continuously higher, reaching 103° on the 31st. The bowels, which had previously been constipated, acted once daily, the stools being loose and of pea-soup consistency and appearance. Rose-coloured spots similar to those seen in typhoid fever appeared on Jan. 28th and for a few days following. No enlargement of the spleen could be detected. No cause for her symptoms could be traced to the operation. On the 30th the Clinical Research Association reported: "This serum does not show the reaction characteristic of typhoid fever." On Feb. 4th a similar report was received, but with the suggestion that "possibly the case is one of paratyphoid." On the 5th the patient was removed to the isolation hospital. On the 8th the Clinical Research Association reported: "With paratyphoid strain B, this serum gives clumping reactions with dilutions of 1–10, 1–25; with a 1–50 test the reaction obtained was very feeble. We again tried the serum with two different strains of B. typhosus. No reaction was obtained even with the 1–10 dilution. The results obtained with the paratyphoid strain were not sufficiently marked to be conclusive." On the 9th a report from Dr. G. L. Eastes stated: "A moderate amount of clumping was obtained when mixing the blood with a broth culture of the paratyphoid bacillus of Brian and Kayser in all dilutions up to 1 per cent." On Feb. 5th the evening temperature reached 103°; on the 6th, after 16 days of fever, it dropped to 98·6° and did not rise again. The fall of temperature was accompanied by profuse sweating. On the 20th the patient was discharged recovered from the hospital.

I have considered the case worthy of record, it being the first of its kind that I have come across. It is probable that examples of this disease occur more frequently than is supposed and many must be overlooked. When it is diagnosed and treated as typhoid fever no harm can result; but when, as in my case, Widal's reaction for typhoid fever is repeatedly found to be negative and the case is a mild one the diet is likely to be less restricted than it should be, disinfection may be neglected, and the consequences may be serious. ~~It is only by a bacteriological examination of the blood that~~ typhoid and paratyphoid fevers can be distinguished. The fact that the pedicle was doubly twisted adds additional interest to the case.

High Barnet.

ROYAL METEOROLOGICAL SOCIETY.—The annual dinner of the Royal Meteorological Society will be held at the Trocadéro Restaurant, Piccadilly, W., on Tuesday evening, June 18th. The dinner will be at 7.0 P.M. and the price of the tickets will be 20s. with wine or 8s. 6d. without wine. Application should be made to the assistant secretary, 70, Victoria-street, Westminster, S.W., by June 4th.

PERFORATION IN TYPHOID FEVER AND ITS RELATION TO THE BLOOD PRESSURE;

WITH A REPORT OF FIVE CASES.

BY A. LEWIN SHEPPARD, M.B., B.S. DURH.,
HOUSE PHYSICIAN TO THE BRISTOL ROYAL INFIRMARY.

ONE of the signs of perforation of the intestine in typhoid fever that have recently been brought to our notice is a rise of blood pressure immediately following the catastrophe. At present, however, so few records have been published that Janeway[1] remarks that "full reports of all such cases should be made, that the value of the blood pressure chart, both as positive and negative evidence of perforation, may be established."

During the past year I have had the opportunity of observing an epidemic of an exceptionally severe type, in which 45 per cent. of the fatal cases were due to perforation, and as the blood pressure was carefully watched in each instance the results should be worth recording. I am indebted to Dr. J. E. Shaw, Dr. F. H. Edgeworth, and Dr. A. B. Prowse, under whose care the cases were admitted, for allowing me to do so. Up to the present time five cases have been reported by Crile,[2] who found that the blood pressure rose in every case immediately after perforation, as his figures show.

No 1	Blood pressure	rose	from	116 to 190 in four hours.
No. 2	„	„	„	84 „ 110 promptly.
No. 3	„	„	„	116 „ 165 in two hours.
No. 4	„	was 155.		Previously unknown.
No. 5	„	„ 223.		Previously unknown.

The same observer found the average blood pressure in 115 cases of enteric fever to be 104, varying between 138 and 74, the pressure as a rule gradually decreasing till the fourth or fifth week, when the average was 96 and 98.

In 41 cases where I made observations during, or about, the fourth week, the average blood pressure was 98. Briggs[3] also records a case in which the blood pressure rose from 106 to 144 in four hours and four hours later the patient suddenly developed typical signs of perforation. This anticipation he explains by suggesting that the resultant inflammation did not reach the parietal peritoneum for eight hours after the accident. He also mentions a case showing a negative result, in which the pulse rose from 152 to 170, and the leucocytosis from 7000 to 17,000, with no rise of blood pressure and no perforation.

The following is a brief summary of the cases I have observed.

CASE 1 (under the care of Dr. Shaw).—A man, aged 20 years, was admitted on the twenty-first day. It was a typical severe case. On the twenty-fifth and two following days there was slight hæmorrhage in the motions. On the twenty-ninth day the blood pressure was 88. On the next day at 4 P.M. the temperature was 100·2° F. and the pulse was 120. At 4.30 he complained of abdominal pain and at 6.30 the pulse was 140 and the blood pressure was 116. The pulse rose to 170 at 9.0, but at 10.30 it had fallen again to 130 and the blood pressure to 90. Leucocyte counts made at 6.30 and 10.30 were 5330 and 5740 respectively. The surgeon then saw the case but did not advise operation as the patient appeared better. 26 hours later laparotomy revealed a large perforation, at which time the pulse was 136, the blood pressure was 92, and the leucocytes had only risen to 5945. The patient died two hours later.

CASE 2 (under the care of Dr. Shaw).—A girl, aged 19 years, was admitted on the sixteenth day. The attack was a mild one. The blood pressure was 97. She got worse till the forty-third day, when she had a rigor, after which the temperature fell during the night from 103·2° to 97·8° F. The pulse was 116, the blood pressure was 94, and a leucocyte count gave 3660. On the forty-seventh day at 5.15 P.M. she said that she had had pain since 4 o'clock, but it was now worse. At 5.30 the pulse had risen to 150 from 120 and the temperature to 102° from 100°, and there was a leucocytosis of 11,160. The blood pressure was not below 110, but the patient was too restless and the pulse too small to allow an estimation with any accuracy. Laparotomy at 6 P.M. showed a small perforation and about six inches higher up the gut a patch of less recent peritonitis, which probably meant that there had been a slight leakage from another ulcer four days before, when the rigor had occurred. The patient died in four days. Widal's reaction in this case was always negative, though tried five times.

[1] The Clinical Study of Blood Pressure, p. 226.

[2] Journal of the American Medical Association, 1903, vol. xl., p. 1292.

[3] Boston Medical and Surgical Journal, 1903, vol. cxlix., p. 343.

CASE 3 (under the care of Dr. Shaw).—A man, aged 24 years, was admitted on the fifteenth day. The blood pressure was 136. It was a typical case. On the twentieth day he complained of abdominal pain at 5 P.M. The blood pressure was 120, the pulse was 94, and the temperature was 101·2° F. At midnight the temperature was 104·8° but the pulse had not risen. 12 hours later the pulse was 80, the temperature was 98·2°, and the blood pressure was still 120. The leucocyte count was 8800. The pain continued and he vomited. The diagnosis was doubtful but in any case he was considered to be too bad to operate. Signs of peritonitis became definite and the patient died on the next day. There was no post-mortem examination but perforation had undoubtedly occurred.

CASE 4 (under the care of Dr. Prowse).—A man, aged 34 years, was admitted on the twenty-fifth day. It was a very severe case. Slight hæmorrhage occurred on the twenty-ninth day. The pulse was 124, the temperature was 105° F., the blood pressure was 112, and the leucocytes were 6400. Some pain was present. The motions became of normal consistency and well formed about the fortieth day. On the forty-third day he had a rigor and was distended, sweating, and delirious. The blood pressure was low but was not able to be estimated exactly owing to the restlessness of the patient and the smallness of the pulse. The leucocyte count was 11,600. There was subcutaneous hæmorrhage on the right side of the buttock. There was hæmorrhage in the motions on the forty-fourth, forty-sixth, and fifty-third days; and on the sixtieth day, the blood pressure then being 94, there were three violent hæmorrhages from the bowel, about three pints in all. He collapsed and died. The pulse could not be felt. Post mortem there were adhesions between the intestines and abdominal wall. All ulcers but three had healed. The base of one was entirely gone and the abdomen was full of blood. The other two ulcers had destroyed the coats of the bowel down to the peritoneum. In this case the perforating symptoms were masked by the hæmorrhage, but observations made during the course of the illness were interesting, though negative on account of the continual weakness of the pulse.

CASE 5 (under the care of Dr. Edgeworth).—The patient was a youth, aged 18 years, who had walked about till admission on the fourteenth day. It was a typical case. On the seventeenth day the blood pressure was 90. On the nineteenth day the pulse was 112; there was very slight abdominal pain all night. At 5 A.M. the pulse was 116 and the temperature was 101° F. At 7 A.M. the pulse was 152. At 8.30 the pulse was 158, the temperature was 101·2°, the blood pressure was 92, and the leucocyte count was 4800. The patient died at midday. Post mortem several acute and deep ulcers were found. One had perforated.

The accompanying table shows the various symptoms as they followed perforation.

Looking at the table we see that the *pulse* rose in four cases, and in No. 5 was the only marked feature. *Peritoneal symptoms* were diagnostic in one case, while some pain was present in all. The *temperature* rose in three cases but fell later. *Leucocytosis* was marked in Case 2, but here other signs were also unmistakeable. In the other cases there could have been no great rise although the previous figures were not known. The *blood pressure* with which we are chiefly concerned here was in no case the only sign, and no great rise was recorded in any, the maximum change being only 28 mm. Hg. In Case 2 the pressure probably exceeded 110, but here, as in Case 1, there were other signs equally valuable and more decisive.

Conclusions.—From these results the rise of blood pressure does not appear to be as certain, and consequently as valuable, a sign as Crile's figures would indicate. The signs of perforation, however, are notoriously uncertain; and in no case of typhoid fever with fairly sudden abdominal pain, combined with any one well-recognised sign (providing there is no other ascertainable cause), should we hesitate to diagnose a perforation. Amongst these signs should certainly be placed a rise of blood pressure. It seems quite as constant as leucocytosis, and is certainly more easy to observe and chart throughout the course of the disease. A disadvantage that may arise, as I found in Case 2, is that owing to restlessness it may be impossible to make an accurate estimation. It will not be common to meet with cases like No. 4, where violent hæmorrhage occurring with perforation renders the pulse imperceptible. In any such case, however, the seriousness of the condition is obvious and the loss of the knowledge of the blood pressure immaterial. All my estimates were taken with Martin's modification of a Riva-Rocci sphygmomanometer.

In the diagnosis of perforation we must remember that the signs are nearly always most marked about two hours after the accident has occurred, after which they are usually found to return to their previous conditions and consequently impressions likely to be made on those who see the case at a later stage are often liable to be misleading. The change in blood pressure is no exception to this rule as the tendency seems for it to fall again to its original level as rapidly as it has risen.

TABLE SHOWING THE VARIOUS SYMPTOMS AS THEY FOLLOWED PERFORATION.

Case.	Pain.	Pulse-rate.	Temperature.	Leucocyte count.	Blood pressure.	Peritonism.	Vomiting	Collapse.
1	Slight.	120 to 170 in 4½ hours, followed by fall to 130.	100·2° to 104° F. in three hours, followed by fall.	5945 after 30 hours.	88 to 116 in two hours, followed by fall to 90.	Slight.	No.	No.
2	Yes.	120 to 150 in two hours.	100° to 102° F. in two hours.	3600 to 11,160 in two hours.	94 to 110 (or more) in two hours.	Decided.	No.	Yes.
3	Slight.	94; no change.	101·2° to 104° F. in seven hours, followed by fall to 98·2° 12 hours later.	8800 maximum.	120; no change.	Late.	Yes.	No.
4	Yes.	*128 to 160; running.*	98° to 97° F.	Previously 11,600.	Impossible to estimate.	Yes.	No.	Extreme.
5	Slight.	116 to 150 in two hours	101·2° F.; no change.	4800 maximum.	92; no change.	Slight.	No.	Late.

With the exception of *one case* with severe bronchitis in an old woman in whom the pressure rose from 114 to 130, the negative evidence in the above cases and in others I have investigated has gone to prove that there is no sudden rise of blood pressure in any of the other complications—in which this sign probably stands by itself—as distension, slight pain, leucocytosis, and a rise of pulse may each occur in other circumstances. Summing up, therefore, we may generally regard a rise of blood pressure as positive evidence of perforation; although a stationary pressure is no indication that the catastrophe has not occurred.

Royal Infirmary, Bristol.

EVERSFIELD CHEST HOSPITAL, ST. LEONARDS-ON-SEA.—At a meeting of the committee of the above-named hospital in the offices of the honorary solicitor, Mr. J. Sladen Wing, 1, Delahay-street, Westminster, held on April 27th, Mr. Edmund S. Hanbury being in the chair, to consider the necessity of increasing the accommodation, enlarging the out-patient department, and considerably widening the existing balconies that more patients might be able to undergo the open-air treatment than at present is possible, the solicitor announced that a client of his had offered £1000 to help to carry this project into execution.

STATUS LYMPHATICUS.

BY LOUIS VINTRAS, M.D. DURH.,
PHYSICIAN TO THE FRENCH HOSPITAL AND DISPENSARY.

THE status lymphaticus is a well-recognised condition on he continent, and especially in France, where "*nature ymphatique*," "*constitution lymphatique*," and "*sujet lymphatique*" are current terms. As its name implies, the status lymphaticus is more a constitutional condition than a disease *per se*. In the "Manual of Practical Medicine" of Hufeland, physician to the King of Prussia, translated into French by Jourdan in 1848, there is a concise and very fair description of this condition in the chapter on Diagnosis. "Laxity of the fibres, flesh spongy and flabby, pastiness, paleness, want of warmth; subjects having this constitution are sensitive to cold and in complexion ordinarily fair; they have a disposition to catarrhs, to accumulations of mucosities in the organs of the head, of the chest and of the pelvis, to serous and lymphatic extravasations, to discharges and passive congestions, to incomplete crises and to a general tendency for their ailments to assume a chronic character." Hufeland makes a useless division between what he calls watery or relaxed constitutions and lymphatic or mucous constitutions, since he gives the same description for both and they are evidently one.

Though scientists have long been fully alive to the importance of this condition. it is astonishing how small is the attention which has been given to it; but this probably arises from the paucity of our knowledge of the diseases, and, indeed, of the physiology, of the lymphatic system. In some way or other the lymphatic diathesis has during the last 20 years or so receded from the attention of the medical mind and has been variously mixed up with neurotic, scrofulous, tuberculous, and even syphilitic conditions. The confusion with neurotic tendencies has only been the result of the overwhelming interest taken in nervous diseases and a readiness to include every morbid condition insufficiently understood in this convenient and fashionable category. But the lymphatic and neurotic temperaments have but few points in common and the former subjects are less prone than many others to neurotic affections. Of course, a morbid condition of the nervous centres may influence the lymphatic system as it may influence the circulatory or muscular systems or any organ of the body.

That there is no connexion between the lymphatic diathesis and the other conditions enumerated Trousseau emphatically stated already in 1868, in his "Clinique Médicale de l'Hôtel Dieu de Paris." In the ninety-sixth lecture, speaking of the etiology of adenie, he says: "Can we attribute the lymphatic affection to any known diathesis? Can the constitutional diseases known as scrofulous, tuberculous, cancerous, and syphilitic be invoked to explain the generalised hypertrophy of the ganglions? Evidently no ......" And after giving his reasons for this opinion he continues: "We are thus constrained to admit the existence of a new, *special* diathesis, unknown in its essence, and which we will call *lymphatic diathesis*. This diathesis would be characterised by the tendency in certain subjects to present, under a determining cause, ganglionic enlargements at first localised and which become generalised in the space of from eighteen months to two years." Trousseau here speaks as though adenie were the only morbid manifestation of this diathesis, but we have made progress since those days and have a wider perception of the range of affections of the lymphatic system. It is this question of glandular enlargements which has brought about the confusion between this and other constitutional conditions, for it has been sought to establish a connecting causative link between the idiopathic enlargements of adenie and the secondary enlargements of other diseases due to irritation or absorption. There can be no such connecting link and this once established clears the way for a definite understanding of the particular condition under consideration. The lymphatic diathesis is not easy to diagnose but the following data will afford some help. It occurs mostly among tall, rather sparsely built subjects, with fair, clear skins, rather pale, but not with the dead white pallor of anæmia. The pastiness alluded to by Hufeland is only a much later symptom and may not be present at all. They are of a slow sedentary habit of life, they are mostly highly intelligent but in a deep earnest way; they are self-concentrated, shy with strangers, and of a retiring disposition, but genial and brilliant when at their ease among friends. They are very sensitive to climatic influences and they feel the cold keenly. They are in appearance listless and careless and give the impression of being indifferent to things in which inwardly they are greatly interested. They are emotional but suppress their emotions. Their fits of anger are concentrated and they are still and turn to a death-like pallor, where others flush red and fly into a passion. There is nothing about them of the spasmodic excitability of the nervous temperament, nor of the hopefulness of the tuberculous temperament. Their pulse is usually slow, sometimes very slow, averaging as low as 45 to 50; but under the stress of worry or emotion their pulse-rate will rise to above 100 and remain so for days and even weeks without any apparent ill-effects. It is the same with the heart beats, and it is this which constitutes one of the chief dangers of this condition. Under some strong emotion, but often without any cause, the ratio of the heart beats will double or treble, not in the irregular way, typical of nervous palpitations, but with a steady rise, the heart maintaining a perfectly regular but highly accelerated action. I believe that in these cases the flabby walls of the heart become suddenly dilated and as suddenly return to their former state. It is quite comprehensible that during such a paroxysm any interference with the nerve centres may cause the dilated walls of the heart to cease contracting. I think that this accounts for many cases of sudden death where no adequate pathological lesion seems to exist. In such subjects the muscles are mostly semi-relaxed, and are rarely in a state of tension; they never, so to speak, stand at attention. They have a peculiar stoop, which is not due to any deformity of the chest or any weakness of the spine, but to this relaxed condition of the muscles of the back and neck. The skin is also relaxed and soft, with a marked tendency to local excessive action of the sweat glands, especially those of the hands and feet. The hair is thin and silky and falls early. There are a lack of brilliancy in the eyes, which are often watery, and a distinct want of fixity in the gaze due merely to the flabby and usually relaxed condition of the muscles of the eyeball. The same condition of the facial muscles often gives a vacant expression which disappears when the attention or interest of the subject is roused. In fact, whereas we describe the nervous subject as being overstrung we may aptly describe the lymphatic subject as being generally understrung.

Such subjects it is in whom a cold in the head or an attack of bronchial catarrh will drag on for weeks and even months, in spite of treatment, and then cease suddenly without any reason; in whom gonorrhœa, notwithstanding the greatest care, will degenerate into gleet, and after months, or even years, finally disappear in the same inexplicable way or, on the other hand, set up joint trouble, the effects of which may be irremediable. An attack of pleurisy is particularly dangerous to the lymphatic subject as the pleural cavity when emptied will fill again and again with despairing persistency. With them the recovery from acute diseases is always tedious and they are subject to relapses. A slight injury will often cause the gradual formation of a cold abscess which may attain a size out of all proportion to the cause. It is unnecessary here to multiply these examples and I will only add that, if the lymphatic temperament has some very decided disadvantages, it has also certain advantages, for as far as my experience goes it seems less liable than other constitutions to neurotic and tuberculous affections. The status lymphaticus has also a distinct tendency to improve with advancing years, and where it has caused no serious organic lesions the subject will comparatively feel stronger and enjoy better health during the second than he has during the first part of life.

Regent's Park-road, N.W.

WHITBY COTTAGE HOSPITAL.—In THE LANCET of Dec. 22nd, 1906, p. 1760, we mentioned that the whole of the honorary medical staff of this hospital had resigned owing to differences of opinion between themselves and the governing body of the institution. Since that date conference after conference has been held between the medical men and the governors during which time the hospital was closed. On May 4th, however, a special meeting was held in the Church House, Whitby, at which it was announced that as a result of the final conference new rules had been drawn up to which both sides agreed. These rules were passed after some minor alterations in details had been made. The dispute may now, therefore, be considered as at an end, though it necessitates the closing of the out-patients' department, for which "Captain Cook's" House was recently bought.

BRADFORD ROYAL INFIRMARY.

A CASE OF CONGENITAL DIVERTICULUM OF THE STOMACH AND DUODENUM IN A PHYSIOLOGICAL HOUR GLASS STOMACH.

(Under the care of Mr. W. H. HORROCKS.)

FOR the notes of the case we are indebted to Dr. A. W. Falconer, late house physician.

The patient, a male, aged 54 years, was admitted into the Bradford Royal Infirmary on Sept. 18th, 1906, under the care of Mr. W. H. Horrocks, suffering from a self-inflicted gunshot wound of the head and died within a few minutes of admission.

On opening the abdomen the stomach was found lying obliquely extending downwards and to the right, the pylorus being hidden under the liver. In the middle of the greater curvature was a marked constriction dividing the stomach into two almost equal parts. On removal the stomach was quite empty, it having previously been washed out under the impression that the man might have taken poison. It was markedly bi saccular, the division being caused by a tucking in of a portion of the greater curvature, forming a tube about 2½ inches in length, which felt thicker than the rest of the stomach wall, the lower curvature showing no indentation. Arising from the pyloric canal on the greater curvature was a diverticulum about half an inch in length, and on the upper wall of the duodenum just past the pylorus was a similar diverticulum somewhat less in size. The measurements of the stomach when laid flat on the table were as follows. Length from fundus to pylorus 12 inches, vertically in cardiac portion 5½ inches, at the constriction 3 inches, and in the pyloric portion 4½ inches. On opening the stomach the thumb could be passed through the constriction in the middle of the stomach and the tip of the little finger insinuated through the pylorus. The diverticulum in the stomach admitted the forefinger and a distinct thickened ring of tissue was felt nipping the finger at the base of the duodenum. It was three quarters of an inch in diameter and three quarters of an inch in length. The duodenal diverticulum was half an inch in diameter and half an inch in length, and the same ring, though less marked, was felt at the entrance to the diverticulum. There were no adhesions or any signs of inflammation. The diverticula could be readily inverted and were covered by mucous membrane, which showed no tendency to be thrown into folds The mucous membrane of the stomach in the cardiac portion was slightly injected; in the pyloric portion it was normal. On the posterior wall at the cardiac end of the pyloric half there was one small scar involving the mucous and submucous coats. The mucous membrane in the constricted portion was thrown into numerous longitudinal folds and felt much thicker than in the rest of the stomach. Sections were made through the entrance to the stomach diverticulum, and at the entrance to the diverticulum great thickening of the muscular coats was found, involving both the circular and longitudinal folds but to a somewhat greater extent the circular folds. The thickness of the muscular wall at this part was $\frac{3}{16}$ths of an inch. Just past the muscular thickening the normal stomach mucous membrane was suddenly replaced by a glandular tissue consisting of lobules composed of alveoli lined by polyhedral cells closely resembling those of the pancreas. Between the lobules there was some slight small cell infiltration. Sections were also made through the constricted portion of the stomach which was found to be normal, the muscular coat not being thickened and the apparent increased thickness of the mucous membrane being due to the number of its folds.

Remarks by Dr. FALCONER.—The occurrence of congenital diverticulum of the stomach is of extreme rarity. It differs from the very much more common variety of acquired diverticulum in the fact that it is composed of all the coats of the stomach and not only of the mucosa and submucosa, as most of the acquired or false diverticula are; and, further, the congenital diverticula sometimes contain glandular tissue foreign to the stomach. Weichselbaum[1] records an almost identical case with the present one in which at the bottom of a diverticulum near the pylorus there was a nodule of the size of a hemp seed which showed the structure of the pancreas and on the anterior duodenal wall an accessory pancreas as large as a bean covered by the serous coat. Accessory pancreatic tissue in the stomach wall has also been recorded by Klob, Wager, and Gegenbauer. In the duodenum alone accessory pancreatic tissue is rather more common, cases having been recorded by Weichselbaum and Zenker and Mr. Low of the Aberdeen Anatomical Department also tells me he has seen several such cases (unpublished). The occurrence of hour-glass constriction of the stomach associated with an obvious congenital diverticulum might at first sight suggest the possibility that they were both congenital conditions but I do not think there are the slightest grounds for such a supposition. It showed all the characteristics of the condition for which Professor Cunningham has suggested the term physiological "hour-glass stomach," the main points of which are that the constriction is solely due to a tucking-in of the greater curvature, the lesser curvature showing no abnormality and the presence of marked longitudinal folds of the mucous membrane suggesting that the condition is but temporary. Professor Cunningham[2] concludes that the condition is due to a localised spasmodic contraction of the muscular coat which most commonly arises at the physiological subdivision of the stomach into a cardiac and pyloric portion but which may arise at any part between this and the pylorus.

I am indebted to Mr. Horrocks, senior surgeon to the Bradford Royal Infirmary, for permission to publish this case.

PATHOLOGICAL SOCIETY OF LONDON.

The Morbid Histology of the Suprarenal Glands.—A Case of Inoculated Syphilis in the Chimpanzee.—A Rare Variety of Cardiac Degeneration.

A MEETING of this society was held on May 7th, Dr. P. H. PYE-SMITH, the President, being in the chair.

Dr. F. A. BAINBRIDGE and Mr. P. R PARKINSON communicated a paper on the Morbid Anatomy of the Suprarenal Glands. They said that suprarenal glands obtained from 50 consecutive post-mortem cases had been examined by Kohn's method; the depth of the chromaffin stain in the medulla of the glands indicated the amount of adrenalin present. Control observations showed that the amount of chromaffin substance was not appreciably lessened during the interval between death and the post-mortem examination. It was found that the adrenalin had entirely disappeared in cases of death from acute general infections or from post-operative shock, whereas it was still present in normal or almost normal amount in chronic diseases. Several cases were examined which showed arterial disease after death and in which the blood pressure during life had apparently been raised. In these the suprarenals were sometimes slightly enlarged, but no adenomatous growths were observed; the depth of the chromaffin stain was very intense and the amount of adrenalin stored in the medulla appeared to be excessive. The observations suggest that in acute disease, where the blood pressure was low, the suprarenal glands yielded up their store of adrenalin, whereas in conditions associated with high blood pressure adrenalin existed in the suprarenals in normal or increased amounts.

Dr. A. S. GRÜNBAUM read notes and showed specimens of a case of Anthropoid Syphilis. A male chimpanzee, inoculated on the right eyebrow, developed a chancre after 14 days and a secondary rash, principally on the face, after nine weeks. Treponema pallidum was found in both lesions but not after the thirteenth week. The animal died just 11 months after inoculation. Two months before death it had a fit of Jacksonian epilepsy, followed a week later by a second fit. The temporary paralysis of the left side and the loss of speech disappeared after a few hours, but paresis and twitching of the limbs persisted, although diminishing, until death. There was no optic neuritis. Post mortem numerous minute hæmorrhages, confined almost entirely to the right side and chiefly in the cortex, were found in the brain along the vertex from front to back. They were due to the rupture of small, probably preceded by thrombosis of the smallest, vessels. Fibroid degeneration of, and leucocytic infiltration around, vessels could be seen in some parts. There was no meningitis. In the liver were small areas of commencing infiltration and fibrosis. Typical syphilitic fibrosis was present in the testes. There was no affection of the bones, and except for some colitis and old tuberculous glands the other organs were healthy. The serum sent to Breslau was reported from Neisser's laboratory to show the presence of syphilitic antibodies. No treponemata were found in either the cerebro-spinal fluid or the organs.

[2] The Varying Form of the Stomach in Man and the Anthropoid Ape, Transactions of the Royal Society of Edinburgh, vol. xlv., Part 1.

Dr. W. O. MEEK showed microscopical preparations from a Heart the seat of Diffuse Calcareous Degeneration. The calcareous deposit was in the form of fine granules partially soluble in dilute acids. The etiology of the condition was obscure, the intervening areas of cardiac muscle being normal and no vascular changes being found to account for it.

OBSTETRICAL SOCIETY OF LONDON.

Intra-peritoneal Rupture of the Bladder occurring during Labour.—Malignant Vaginal Polypus Secondary to an Adrenal Tumour of the Kidney.

A MEETING of this society was held on May 1st, Dr. H. R. SPENCER, the President, being in the chair.

Mr. C. E. PORTER read a short communication on a case of Intra-peritoneal Rupture of the Bladder occurring during Labour. The patient, a primipara, aged 32 years, who had never complained of previous bladder trouble of any kind, was seen 48 hours before labour had really commenced on account of vague pains which were referred chiefly to the sacral region and which were thought by her to be labour pains. There was then no undue distension of the bladder to be made out by abdominal examination. Urine had been passed that day. Two days later labour pains started in earnest but medical aid was not summoned until 12 hours had elapsed. The nurse in attendance gave a history that labour had been progressing in the ordinary way for about 12 hours when during a pain the patient suddenly cried out that "something had given way inside" and from that moment she became very ill indeed. When seen the patient looked very ill, the pulse was very rapid, the tongue was dry, and the abdomen was much distended and tympanitic. Ordinary labour pains were not to be distinguished from the acute general abdominal pain complained of, though some contractions of the uterus were still to be made out. The child was lying in the first vertex position, the os uteri was fully dilated, and the head was well down in the pelvis. Labour was not apparently obstructed except by the absence of efficient uterine contractions. It was thought that some grave intra-peritoneal catastrophe had complicated labour, and in view of the serious condition of the patient chloroform was at once administered and a full term, well-nourished male child was easily delivered with forceps. After some post-partum hæmorrhage the uterus contracted down well. The umbilical cord was nearly pulseless on delivery and the child died in about an hour. The general abdominal pain ceased to be complained of after delivery. The general condition of the patient had not improved five hours afterwards, the pulse and respiration being still very rapid, and the abdominal distension considerable. 24 hours after delivery the patient had not passed urine, had vomited frequently, and was obviously worse. It was decided to risk her removal to hospital eight miles distant. On admission she was much collapsed. A catheter specimen yielded about four ounces of almost pure blood. The patient was anæsthetised and the abdomen was opened in the middle line below the umbilicus. A considerable quantity of urinous fluid mixed with serum escaped from the general peritoneal cavity. The stomach was enormously distended with gas which was evacuated by a small trocar thrust into the anterior wall of the stomach after extending the abdominal incision upwards. This made examination much easier and a small vertical rent about one and a half inches long was found in the upper and posterior aspect of the bladder to the right of the middle line. This was closed by Lembert sutures and the abdomen sewn up with silkworm gut, the lower angle of the wound being drained with a large rubber tube. The patient was not very markedly worse for the operation but died from shock about six hours later. No necropsy was allowed.

Mr. ALBAN H. G. DORAN read a paper on a case of Malignant Vaginal Polypus secondary to an Adrenal Tumour of the Kidney. A married uniparous woman, aged 40 years, suffered from rigors and sweats in September, 1906. A mass was detected in the vagina and a small tumour in the right iliac fossa. The vaginal growth was a racemose body attached by a well-defined pedicle to the lower part of the anterior wall of the vagina; its lobules, more or less necrosed, were shed from time to time. In November Mr. Doran removed the abdominal tumour, which proved to be a malignant adrenal growth in the upper part of the right kidney. The patient declined to allow a second operation for the extirpation of the vaginal growths. She survived the nephrectomy three months. After death secondary deposits were discovered in the liver and right lung; their presence in the lung had been diagnosed before death. On microscopical examination it was found that the vaginal tumours, as well as the growths in the liver and lung, were of the adrenal type and therefore secondary to the tumour in the kidney.—Dr. BECKETT OVERY described a similar case in which a polypoid mass had been found attached to the anterior vaginal wall. This was removed and a large tumour in the right side of the abdomen was discovered. Two months later the vaginal growth had recurred and it was again removed. The patient died a month later. The post-mortem examination showed that the abdominal tumour was primary and was a malignant adrenal tumour starting in an adrenal rest. There were numerous secondary deposits in the liver and lungs, sections of which showed more or less typical adrenal tissue.—Mr. DORAN replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Differentiation of the Varieties of Extra-systole.—Muscular Lesion occurring in Sprue.—Intubation of the Larynx in Laryngeal Diphtheria.

A MEETING of this society was held on May 1st, Dr. GEORGE HUNTER, a Vice-President, being in the chair.

Dr. W. T. RITCHIE read a paper on the Differentiation of the Varieties of Extra-systole. After reference to the researches of Tawara and of Keith and Flack upon the muscular connexions between the superior vena cava, the auricles, and the ventricles, it was pointed out that an extra systole was the evidence of the heart's response to a heterotopic stimulus. The general characters of the pulse in extra-systolic irregularity were described and it was shown that by an analysis of graphic records demonstrating the sequence in which the auricles and the ventricles contract during an extra systole and the time interval between their contractions on that occasion the initial point of heterotopic stimulation might be deduced. The distinctive features of the varieties of extra-systole were then described. According to the initial point of heterotopic stimulation three main varieties of extra-systole—the auricular, the auriculo-ventricular, and the ventricular—might be recognised. When an auriculo-ventricular extra-systole occurred the auricular beat might be premature as well as the ventricular, and the former might then precede, coincide with, or follow the latter, according to the portion of the auriculo-ventricular bundle first stimulated. It was suggested that the auricular beat preceded the ventricular in the case of supranodal and nodal auriculo-ventricular extra-systoles; when the mid-point, probably the main stem, of the bundle was the initial point of stimulation the auricular and ventricular beats coincided; in other cases of infranodal auriculo-ventricular extra-systoles, when the ventricular beat preceded the auricular, the heterotopic stimulus probably proceeded from the ventricular ramifications of the auriculo-ventricular bundle. In the latter instance the auricular extra-systolic wave might be premature or the auricular rhythm might be unaltered. Cases of continued cardiac irregularity resulting from auriculo-ventricular extra-systoles in series were recorded and in conclusion the three forms of ventricular extra-systole—the retrograde extra-systole, the interpolated extra-systole, and that with a period equal to the succeeding physiological systole, as observed in cases of heart block—were described.

Dr. BYROM BRAMWELL read a communication on a hitherto undescribed Muscular Lesion occurring in Sprue, with a pathological report and microscopical examination by Professor Robert Muir.—Dr. GEORGE HUNTER, Dr. BLACK, and Dr. G. A. GIBSON took part in the discussion.

Dr. CLAUDE B. KER read a paper on Intubation of the Larynx in Laryngeal Diphtheria. He said that while in America, in France, and in most European countries intubation had been enthusiastically adopted as the operation of election in laryngeal diphtheria, it had not had many votaries in Great Britain. Only recently had it met with any serious consideration and even now those who preferred it to tracheotomy were few in number. The theoretical advantages of intubation over tracheotomy were: (1) that the patient continued to breathe *per vias naturales* and consequently there should be less chance of pulmonary sequelæ; and (2) that a cutting operation was avoided and no scar was left. No preparation was required and the patient was as a rule relieved in a few seconds. With tracheotomy, on the other hand, the parts chiefly involved in the obstruction were given complete rest and if the tube became dislodged it could be replaced by the nurse, whereas the intubation tube required a medical man to replace it. There was a great difference of opinion whether membranes were expelled more easily by one tube or the other. Larger pieces should theoretically be expelled through the tracheotomy tube; the intubation tube allowed more vigorous and natural coughing. Dr. Ker thought that the danger of plugging of the tube was exaggerated; if it became plugged it usually was expelled or could be pulled out by the nurse by traction on the string and in such an event a reasonable time usually elapsed before it had to be replaced. The danger of rolling up membrane in front of a tube in the act of intubating and so plugging the trachea was a more real one and had happened on several occasions in Dr. Ker's experience, always, however, without fatal result. Another objection was the possibility of infecting the trachea from the larynx by dislodging small portions of membrane by the tube. This objection, however, had no value since the introduction of antitoxin which prevented the extension of membrane if an adequate dose of serum had been administered. The diphtheritic membrane was so rapidly disintegrated after its employment that there was an unquestionable advantage to Dr. Ker's mind in adopting an operation which would tide the patient through a difficulty lasting only two or three days and which avoided the risks of tracheotomy. Since 1894 intubation had been the operation of election at the Edinburgh City Hospital, supplemented, when necessary, by a secondary tracheotomy. Dr. Ker's experience was limited to little more than 200 cases and until three years ago the mortality of the operation never fell below 40 per cent. It was interesting to note, however, that the death-rate of all laryngeal cases was very much the same as that of hospitals where tracheotomy was in vogue. A great improvement, however, in his results followed the systematic introduction of nasal feeding as a routine in all cases of intubation. Previously rectal feeding, or this along with soft foods by the mouth, was depended on. At present Dr. Ker depended entirely on nasal feeding. About the same time, also, he commenced to use vulcanite instead of the old metal tubes and he found that they were much better tolerated and that their use contributed to the improvement in his results. In hospital practice he was convinced that it was to the advantage of the patient to postpone operation as long as possible. Most of the cases were operated upon in the third stage of croup or when the patient was becoming exhausted and the pulse was beginning to fail. Unless during the second stage the paroxysms were very severe indeed it was better to avoid interference as so many of them recovered without operation. The great considerations were to give the serum time to take effect and to be always within reach of the patient and prepared to interfere at a moment's notice. It was obvious that in private practice early operation was desirable. Of the 70 cases intubated in the hospital since the autumn of 1904, 12 were purely laryngeal, in 48 the fauces were also involved, and in the remaining ten the naso-pharynx was also implicated. 19 patients died, or 27·1 per cent. Slightly more than one quarter of the total cases required a secondary tracheotomy, 18 in all being thus treated. As might be expected, the mortality after tracheotomy was high, only severe cases being thus treated. Of the 18, no less than ten succumbed, or over 55 per cent. In 11 of the cases tracheotomy was performed almost at once, as intubation had not afforded sufficient relief, and six of them died, the obstruction having been beyond reach. In only eight cases was tracheotomy successful after intubation had failed, and Dr. Ker thought that tracheotomy was limited in its use to about one-tenth of the total cases which required interference. Of the nine deaths of patients who were not subjected to tracheotomy, three occurred after the tube had been finally removed—two from heart failure and one from broncho-pneumonia. Five cases died with the tube in the larynx but all with laryngeal difficulty relieved; two of these succumbed to heart failure, one from pneumonia, and one from septic infection. Only one patient died during intubation from heart failure. Some surgeons remove the tube after 24 hours, while others leave it in for six days. In Dr. Ker's opinion the right time varied from 48 to 72 hours. In 12 cases intubation was required twice, in three thrice, in one four times, in one six times, in one seven times, and in one 14 times before the tube could be dispensed with. If the patient could do four hours without the tube it was seldom that it required replacement. If the temperature was normal and the respirations did not exceed 30 per minute before extubation, it was hardly likely that re-tubation would be required. The actual length of time that the tube was worn varied from a moment in four cases, where it was immediately coughed out along with membranes and so complete relief was afforded; seven patients wore the tube for less than two days; 17 were extubated in from 48 to 60 hours; five after three days; five after four days; three after five days; in three it was worn until the seventh to the tenth day; one case 14 days; and another 29 days. The cause of obstruction appeared to be occasionally atrophy of the laryngeal abductors from disuse and consequent adductor spasm. More frequently it depended on a subglottic hypertrophic laryngitis. The operation of intubation required considerable practice and was probably more difficult than tracheotomy. The patient should be in the recumbent position during intubation and the string should be attached to the cheek by a plaster strip, so that in the case of blocking the tube could be immediately removed. The presence of the string necessitated the control of the patient's arms by light splints. The use of steam in moderation was advantageous during the first few days while the tube was worn and while there was a risk of its being clogged with mucus, but when it had been worn for a few days Dr. Ker often put the patients in the open air to improve their general condition. The great difficulty of advising intubation as an operation for private practice was the experience which it required. Few practitioners had a sufficient number of cases of croup to acquire the requisite dexterity. Interference should be employed early as soon as laryngeal symptoms became marked; thus tracheotomy was often performed, and rightly, in cases which a hospital staff would not think of interfering with. Intubation was a much less dangerous procedure in such cases, and in slight cases it allowed time for the antitoxin to act, and the tube could often be removed on the next day. In country practice Dr. Ker would be inclined to intubate every case of laryngeal diphtheria as soon as it had been diagnosed, provided the obstruction were not very marked, in which case he thought that tracheotomy would be the safer method.—Dr. JAMES RITCHIE, Dr. JOHN MACMILLAN, Mr. C. W. CATHCART, and Mr. DAVID WALLACE took part in the discussion, and Dr. KER replied.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on April 10th, Dr. A. Hill Griffith, the President, being in the chair.—Dr. J. Dreschfeld showed some specimens of Hypertrophic Cirrhosis of the Liver.—Dr. W. Milligan and Dr. D. L. Sewell made a short communication upon the Various Routes of Pathogenic Invasion in Cases of Intracranial Sepsis Secondary to Suppurative Middle-ear Disease. Special reference was made to the various sites of osseous erosion in the middle ear, such as the tegmen tympani and tegmen antri. The various intracranial lesions more usually met with were detailed and the practical importance of following up the route of infection was insisted upon. Reference was also made to erosions upon the outer labyrinthine wall and to the grave prognosis when once the labyrinth becomes the site of purulent disease. Vascular and fibrous routes were also dealt with and the rôle played by the petro-squamosal sinus in the production of septic disease at the base of the brain was emphasised. The spread of purulent processes along the perineural sheaths of the auditory and facial nerves was described and illustrative specimens were shown and cases related.—Dr. J. Lorrain Smith gave a demonstration of specimens illustrative of the Pathology of Inflammation and Ulceration of the Intestine. The specimens included: 1. An example of ulcerative colitis. 2. A case of poisoning by corrosive sublimate. In this case the patient had swallowed three tabloids, each containing five grains of corrosive sublimate. The lesions consisted of a local area of inflammation near the cardiac end of the stomach in which a nodular swelling was found with a necrotic surface. The small intestine of this case was less affected than the large intestine. The cæcum and colon showed intense hyperæmia but no ulceration. 3. A number of specimens illustrating the various forms of intestinal inflammation met with in Bright's disease. Reference was made to the experimental work on the elimination of mercurial poisons and the occurrence of inflammation of the mucous membrane of the intestine in cases where the mercurial salt had been administered by an application on the skin surface. These results were compared with the observations on the increase of ammonia in the intestinal contents in cases of uræmia. It was also pointed out that a simultaneous disturbance of the bacterial regulation of the intestine might form an important element in the causation of the inflammatory conditions.—Other specimens were shown as card specimens.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on May 3rd, Dr. Leonard P. Mark, the President, being in the chair.—A paper was read by Mr. R. Lake on Some Results of Nasal Obstruction. He referred particularly to conditions connected with the special regions of the naso-pharynx, the pharynx, larynx, and ear, and also with the general system, the chest, the general development, and intelligence. He also insisted on the differences existing between the results of structural obstruction of the nose commencing in early life and that arising in later or adult life.—The paper was discussed by the President, Mr. G. A. Garry Simpson, Dr. J. B. Ball, and others.—Mr. George Pernet then read an exhaustive and valuable account of Hæmorrhagic Rashes, dealing with the pathology of these manifestations, the conditions under which they occurred, the differentia in their diagnosis, and with the methods of treatment to be employed. The paper contained many important references to the literature of the subject.—A discussion followed, in which the President, Dr. Phineas S. Abraham, Dr. A. J. Rice Oxley, Dr. Rickard W. Lloyd, and others participated.

Reviews and Notices of Books.

A Text-book of Ophthalmic Operations. By HAROLD GRIMSDALE, M.B. Cantab., F.R.C.S. Eng., Ophthalmic Surgeon and Lecturer on Ophthalmic Surgery, to St. George's Hospital, Surgeon to the Royal Westminster Ophthalmic Hospital; and ELMORE BREWERTON, F.R.C.S. Eng., Ophthalmic Surgeon to the Metropolitan Hospital, Surgeon to the Royal Westminster Ophthalmic Hospital. London: Kegan Paul, Trench, Trübner, and Co., Limited. 1907. Pp. 349. Price 12*s.* net.

THE technique of the individual surgeon is chiefly determined by the instruction which he has received from the masters of the art under whom he has worked. Methods and theories, often dogmatic in form, are handed down in apostolic succession. Only with increasing experience, quickened by such imagination and originality as have been vouchsafed to him, does he extend his somewhat narrow horizon, experimenting with the methods of other schools and devising new modifications on his own initiative. True as this fact is of general surgery, it is even more uniformly true of ophthalmic surgery. So specialised is the subject that the medical student learns little more than the general principles of ophthalmic operations in his pre-graduate days, and such knowledge as he acquires is derived chiefly from elementary text-books. The early period of his career at a special hospital is devoted to out-patient work, and he has few opportunities of learning the details of the technique of major operations upon the eye. It is true that he sees the cases before and after operation and it is possible that he may see the major operations performed, but the field of operation in the case of the eye is so small that he derives little advantage unless he is actually assisting the surgeon.

The student of ophthalmic surgery therefore, more than the student of any other branch of surgery, needs detailed instruction in the minutiæ of the various operations. This is obtained verbally from the teacher and is supplemented in the best schools by practical work upon the dead subject or upon dead pigs' eyes. In such a course both teacher and taught will derive much assistance from a good text-book. Hitherto no good text-book of ophthalmic operative surgery has been available. Beyond the restricted scope of the elementary manual of diseases of the eye the student has had to seek information in scattered treatises and original papers, often difficult to find. Until recently such a work was not attainable even in French or German, though the gap has now been filled by Terrien's "Chirurgie de l'Œil" and by Czermak's monumental treatise. Mr. Grimsdale and Mr. Brewerton have now stepped into the breach for the benefit of English-speaking students.

The scheme which the authors have adopted has been that of describing the principal operations employed for various purposes by different surgeons, so that, as a rule, several alternative operations are given for the same pathological condition. The method has obvious drawbacks, but it has resulted in the production of an extremely useful book. The arrangement of subjects is in accordance with the usual practical course and with the opportunities likely to fall to the lot of the young ophthalmic surgeon in his hospital work. Operations upon the extrinsic muscles and lids are followed by enucleation and its substitutes and operations upon the lacrymal apparatus. Finally, intraocular operations are described—for cataract, after-cataract, and glaucoma—followed by rarer operative procedures upon the cornea, sclerotic, and iris. All the classical operations receive ample attention and many debateable procedures are fully described.

In general we are in thorough agreement with the teaching conveyed but every ophthalmic surgeon of experience has his own ideas and partialities in the performance of individual steps and it would be impossible to please everyone on these minute details. If any criticism is to be offered we think that the authors do not lay sufficient stress upon their own rules of conduct, thus perhaps increasing the value of the book for the accomplished ophthalmologist, while detracting from its value to the beginner, for whom presumably it is written. We can conceive of a work on operative ophthalmic surgery, written by a master of the art from his own individual standpoint and describing in detail the procedures which he himself would adopt in given circumstances. Such a treatise would be invaluable to the beginner—of more practical utility than the work under consideration.

The book is well printed. There are numerous diagrams which are adequate to the purpose but are unnecessarily crude.

Studies in Blood Pressure: Physiological and Clinical. By GEORGE OLIVER, M.D. Lond., F.R.C.P. Lond. London: H. K. Lewis. 1906. Pp. 151. Price 2*s.* 6*d.*

IN this little book Dr. George Oliver describes a new from of hæmomanometer which differs in several respects form the instrument previously employed by him. Dr. Oliver's interest in the subject of hæmomanometry is well-known and in his Croonian lectures delivered before the Royal College of Physicians of London in June, 1896,[1] he gave a full account of the construction and working of various instruments which he had devised for recording variations in the calibre of the radial artery and estimating the colour intensity of the blood. The new hæmomanometer is used in conjunction with armlets or air-bags encircling the part in which the blood pressure is to be determined. Two air-bags are provided, one measuring 12 by 35 centimetres for the arm and forearm, and one measuring 2·5 by 9 centimetres for the phalanges. Air is forced into them by means of a hollow ball provided with valves and squeezed in the hand. The manometer shows pressures up to 300 millimetres of mercury. It is a graduated glass tube connected to the air-bags by stout indiarubber tubing, and in it the air pressure is rendered visible by the compression of a column of air contained between the closed end of the tube and a liquid index. Two other forms of the manometer are also described at pp. 65-67.

Dr. Oliver has not found any appreciable difference between the arterial pressure (systolic and diastolic) taken from the upper arm and that taken from the forearm. In the upper limb the first appreciable fall in the pressure is found at the first phalanx, where the pressure is generally from 5 to 15 millimetres of mercury lower than in the arm. In the ungual part of the finger the fall increases so much that the pressure there is only one-half of what it is in the brachio-radial region, where a diastolic pressure between 95 and 100 and a systolic pressure between 105 and 130 millimetres of mercury are the figures commonly met with. There are, however, some apparently normal persons in whom the readings are habitually higher. A persistent systolic pressure of over 145 or 155 millimetres of mercury recorded within an hour before a meal should be looked upon as somewhat suspicious, and in subjects over 50 or 55 years of age should if possible be reduced by treatment, as it may increase slowly and result in cerebral hæmorrhage or secondary cardiac disease. High readings—e.g., from 160 to 180 millimetres diastolic and 250 systolic—should be accepted at first with some hesitancy, especially when the pulse-rate is raised; and the observer should always remember that when the peripheral resistance is increased the influence of nervous excitement, however slight, becomes much more pronounced than when the distal outflow is normal or subnormal. When the pressure readings are high the observer should look for corroboration in the accentuation of the second aortic sound and in the condition of the ventricle (evidences of hypertrophy, and so on).

The relations of blood pressure to vascular sclerosis have for a long time been a favourite subject of study and hæmomanometry has afforded an explanation of the occurrence of apoplectic seizures and hemiplegias unaccompanied by any apparent thickening of such vessels as the temporal or radial arteries. Generalised sclerosis of the arterioles and of the small arteries cannot be directly recognised during life, but its existence may with a fair degree of certainty be inferred from blood-pressure measurement. Dr. Oliver devotes many pages to the diagnosis and relief of this condition, with shorter references to chronic rheumatic and gouty ailments, chronic interstitial nephritis, various heart diseases, melancholia and mania, insomnia, neurasthenia, cerebral hæmorrhage, and acute febrile diseases.

Practitioners seeking information on this important branch of clinical diagnosis will do well to consult Dr. Oliver's work. Notwithstanding the remark that he has purposely refrained from entering on many by-paths of his subject which presented themselves, we think that some reference should have been made to the effect produced on the blood pressure by the inhalation of chloroform or ether, and by shock or fainting. As a remedy for a sudden and dangerous fall in the blood pressure Dr. George W. Crile, who is mentioned at p. 118 of the book, suggested about five years ago that the patient's body should be inclosed in a kind of indiarubber "combination garment" into which air could be forced.

Injuries of the Eyes of the Employed and the Workm Compensation Act: Problems in Prognosis. By W. BEAUMONT, Surgeon to the Bath Eye Infirmary. Londo H. K. Lewis. 1907. Pp. 160. Price 5s.

WITH the exception of two chapters this book de entirely with the prognosis in cases of various forms injury to the eyes and their immediate surroundings T author in the preface refers the reader to the text books f questions relative to symptomatology and treatment, must be admitted that he will also find there most of t material which is comprised in the book. Special attenti is, however, devoted to the one aspect of the subject and convenient and pleasantly written account is provided. T teaching is sound and trustworthy, though somewh general; more concrete examples from the author's pra tice would have been welcome.

The first chapter deals with the principal Acts of Parli ment referring to the rights of the employed and t giving of evidence. We think the book would have h more practical utility if this portion had been expanded, the expense if necessary of some of the platitudes whic find mention. The remark that a given one-eyed person, "i quite unable to learn to estimate the degree of accommoda tion he is exercising" implies an ability which no on possesses. Such persons acquire the faculty of judgin distance by experience of parallax and minute attention t shadows, and so on. The last chapter deals with malingering. The principal tests for malingering of binocular amaurosis and amblyopia and of uniocular blindness are given briefly.

The subject presented somewhat cursorily in this book i one of great importance and difficulty. The legal luminary is *a priori* antipathetic to the medical witness. Trained in the niceties of deduction from accurate data, he is at a loss amongst the protean possibilities of prognosis. Fighting on his own ground he starts with a handicap which he too often uses to unfair advantage. The advice that "if the medical man does not wish to appear in court he must decline the first suggestion that he should see the patient at all," is seldom applicable, since most such patients are seen in the ordinary routine of hospital work. The medical man can only be compelled to give evidence of fact on a subpœna, except at the express order of the judge. It is unlikely that the latter will demand an expert opinion without satisfactory guarantee that an equitable fee will be forthcoming. This is an aspect of the subject which should have received mention in the book under consideration.

LIBRARY TABLE.

Elements of Physics for Medical Students. By FREDERIC JAMES M. PAGE, B.Sc. Lond., F.I.C. London: Cassell and Co. 1907. Pp. 288. Price 5s.—This little book gives a brief outline of what the author quaintly calls "General Physics" and contains a large amount of information with respect to the special subjects of heat, electricity, sound, and light. A medical student who had really mastered all the principles and details here set forth or indicated could hardly fail to do well at any of his examinations where a knowledge of the four last mentioned branches is required, but the subjects of statics and kinetics are altogether ignored, so that the student must look elsewhere for an account of the so-called mechanical powers, the action of gravity on bodies either falling freely or projected in various directions, the resolution of forces, simple phenomena of rotation, and so on. This is no doubt to be explained by the remark made in the preface that the book has been written with an eye to the syllabus of the examinations of the English Conjoint Board and the Society of Apothecaries. Mr. Page has succeeded in including much matter within a narrow compass, but it must also be acknowledged that he generally appears to assume that his readers either have already some insight into the subjects or else are studying under the guidance of a teacher. For instance, the notice of the dyne and the erg on pp. 5 and 6 hardly makes it clear to a beginner that these units are so small and so ill-adapted for measuring ordinary mechanical effects that the effort of tearing a sheet of notepaper would be equivalent to thousands of ergs. In the explanation of the vernier on pp. 6 and 7, only those having nine divisions of the main scale subdivided into ten parts are mentioned, and there is no reference to the equally useful ones having 11 divisions of the main scale subdivided into ten parts. On pp. 11 and 253 directions are given for determining "the thickness of a plano-convex lens" with a spherometer. This, of course, can be done in that way if required, but the proper use of a spherometer is to measure the curvature of a lens rather than its thickness. Again, on p. 35 one of the causes of variations of atmospheric pressure is said to be "changes in temperature." Meteorologists will appreciate this, but a candidate for examination honours would probably not answer a question of that nature quite so concisely. On p. 51 the description of the experiment with a thread and a soap film appears to us as one that would be incomprehensible to anyone who has not seen the experiment or who has not read Professor Boys's admirable little book on "Soap Bubbles." For students who have made some progress in physics the book will be useful as a summary of leading points and the 230 illustrations which it contains are generally helpful.

---

[1] THE LANCET, June 6th, 13th, 20th, and 27th, 1896.

The Public Health Acts and Other Sanitary Laws and Regulations. By MARTIN ELLIOTT, of the Middle Temple and Western Circuit, Barrister-at-Law, and GILBERT ELLIOTT, L.R.C.P., D.P.H. Lond. London: H. K. Lewis. 1906. Pp. 168. Price 5*s.* net.—This book is specially prepared for the use of those who are studying for a diploma in public health. The joint authors hope that by condensing and summarising sanitary law and the principal by-laws of the Local Government Board into one small volume they have supplied a need which has long been felt by many. The law on each topic is quoted verbatim from the statutes, "the merest tautology, being, in a few instances, avoided." Many cross references are given to facilitate the simultaneous perusal of the parts which should be studied together. Nearly 30 pages are devoted to the Public Health Act, 1875, for this is the parent Act from which most legislation has flowed, and therein are crystallised the main features of the law with which a medical officer of health is required to be familiar. The little book is ably edited and the possession of a copy will, we think, save time and trouble to those who are preparing for the public health diplomas.

Rough Notes on Remedies. By W. MURRAY, M.D. Durh., F.R.C.P. Lond. Fifth edition, enlarged. London: H. K. Lewis. 1906. Pp. 212. Price 4*s.* net.—This new edition of a very useful little book is welcome. It will undoubtedly be a great help to many of the younger members of the medical profession. Dr. Murray advocates greater reliance on the more common remedies; though he recognises that they must be used with great common sense and a due appreciation of their effect in each individual case. Arsenic, belladonna, calomel, and nitrate of silver has each its chapter; and Dr. Murray advocates doses of these drugs which will stagger the young practitioner. He deplores that the so-called "scientific medicine" of to-day, which [illegible] the practical elements of everyday work, is ousting some of the old-fashioned and time-honoured remedies. "Our Mistakes" is the title of one chapter in this little book and therein Dr. Murray gives much advice that is good and may be followed with advantage. Another chapter on the Limitations of Treatment is full of sage counsel to the young, and maybe somewhat nervous, practitioner. The uses of alcohol in the treatment of disease are impartially considered in Chapter XI., and some useful hints to medical men when called upon to give evidence in a court of law form another chapter. Dr. Murray thinks that the south coast watering-places are over-rated and pins his faith to the north, with a preference for parts of Northumberland. The book ends with an appendix and a plan explaining the physical features and geological structure of a part of the valley of the Coquet, by R. A. S. Redmayne, F.G.S. This book is full of most useful information and we thoroughly recommend it to all practitioners of medicine. It is well written and easily read. The author claims nothing more for it than that it is the outcome of 30 years' experience of medical practice which has produced in him an increasing faith in medicines, and calls it "the rough and ready work of an old practitioner."

Plaster-of-Paris and How to Use It. By MARTIN W. WARE. New York: Surgery Publishing Co. 1906. Pp. 88. Price $1.—This is a useful little book giving an account of the way to prepare and to apply the various kinds of plaster splints, including a Sayre's jacket. There is also a chapter on the use of plaster in dental modelling. With the exception of the information on the use of plaster in dentistry there is nothing in the book which an ordinarily intelligent dresser ought not to know on the completion of his six months' dressership, but practitioners who have long left the hospital, and who are possibly only called upon to treat surgical affections requiring the use of plaster at considerable intervals, will find the instructions given useful as a means of refreshing their memories as to the necessary technique.

The History of Edward Pellew (First Viscount Exmouth). A Paper read on board H.M.S. *Exmouth*, by Fleet-Surgeon W. E. HOME. Plymouth: The Western Morning News Co.—We have read this pamphlet with interest and recommend anyone who cares for the history of our fleet and its past heroes to obtain it. It is hardly too much to say that if Nelson had not completed the annihilation of his country's enemies Lord Exmouth would have done so no less surely, for if he had not quite the Nelson touch he had in extraordinary measure the Nelson grit, as the victor of Trafalgar himself bore witness when he replied in answer to Pellew's request to serve under him that he was too good to be second in command to anyone and so gave him a squadron of his own. Pellew certainly had the advantage to serve in a time when a man by personal endeavour might carve out a career for himself in the navy in a manner that the conditions of modern warfare can scarcely again afford, but he deserved every tittle of his honours, not only for his victories but for his personal valour, which he showed no less in repeatedly saving lives from drowning (and once by swimming round his own ship to find a leak) than in his personal share in his victories. The bombardment of Algiers and the freeing of its slaves was a fitting crown to his achievements. Fleet-Surgeon Home has done full justice in this paper to a glorious life.

JOURNALS AND MAGAZINES.

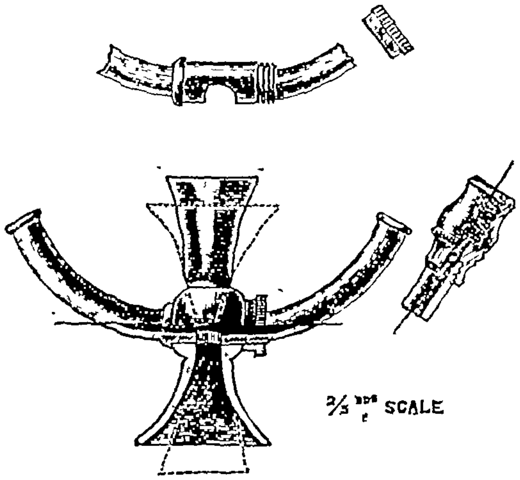
The Phonographic Record. April, 1907. London: Sir I. Pitman and Sons.—The April number of this stenographic journal contains an interesting article on Some Cases of Intestinal Cancer, by Mr. Norman Porritt. In the course of the article he states that the preconception that cancer is necessarily a disease of mature or declining years, like the belief in the *omnipresence of the so-called cancerous* cachexia, is one that cannot safely be held; also that the *theory that a colotomy stays the progress* of rectal carcinoma by diverting the intestinal contents, so that they no longer pass over and irritate the diseased area, is one that seems to him to require qualification. Dr. Edward Walker of Huddersfield relates an anomalous case of cancer of the stomach in a man, aged 39 years, a stone dresser, where the post-mortem examination revealed considerable cirrhosis of the liver and *slight cirrhosis* of the spleen and the stomach was apparently completely filled *by a mass of* encephaloid cancer in the centre of which was a small cavity filled with pus and broken-down cancerous tissue, although the man throughout his illness had no pain, no vomiting, no loss of appetite, and no symptoms of any kind pointing to the stomach as the organ at fault. Dr. A. Hill Joseph writes on Some Points in Urine Analysis and states that in his opinion in the estimation of sugar Gerrard's cupro-cyanide method is the best. The anecdote about "strong feeding for babies," told by a medical man at Ancoats, reveals a tragi-comedy. It is worth repeating. "I was called one day," he said, "to see a sick baby, and found the mother feeding it with little pieces of corned beef. 'My good woman,' I said, 'you must not feed the baby with that sort of stuff.' She replied, 'What am I to feed him with? he doesn't like pork!'"

New Inventions.

AN IMPROVED CHEST-PIECE FOR BINAURAL STETHOSCOPES.

For several months I have been using a newly devised form of chest-piece which I consider an improvement. As will be seen from the illustration, the body is made so that it revolves, the larger end being used for general chest examination, while the smaller is suitable for intercostal and supraclavicular purposes.

The instrument is in three parts—viz., the actual chest-piece, the curved arms to which the tubes are attached, and a metal screw cap which serves either to allow the whole to be taken apart for sterilisation or to make the chest-piece quite rigid. The revolving part is in one piece of metal or ebony, and while in most binaural stethoscopes the ebony part has to be unscrewed for intercostal examination this new and simple device obviates that necessity.



Stethoscopes now in use need not be discarded, for although the illustration is inte

either silk or mohair tubes can easily be fitted by means of the special mount depicted *separately and which is screwed* on to both ends of the arms. The article can be obtained from any dealer in surgeon's instruments.

DAVID ROSS, M.D. Aberd.

KENT'S SANITARY ICE-SAFES AND REFRIGERATORS.

It is somewhat surprising, considering to what purposes they are applied, how little attention has been bestowed upon the design and construction of ice-safes and refrigerators with the view, not only of making them effective for the preservation of food in a sound state, but of insuring during its storage a sanitary environment. A mere ice-box is not *sufficient for the purpose. The insulation* should not only be good but provision should also be made for the passage of clean chilled air through the refrigerator. When attention is carefully paid to the details involved by such requirements the results are highly satisfactory, food is preserved in a *sound, wholesome state, and the* psychical factor of digestion and appetite is not spoiled by the sight of unattractive looking viands. In the patented system of refrigerated ventilation carefully worked out by Mr. George Kent of 199, High Holborn, a continuous pure dry cold current of air passes through the food chamber, carrying off all exhalation and thus preventing the contents tainting one another with their individual odours. Onions, if need be, may thus be kept in company with delicate articles like fish, strawberries, cream, milk, and so forth, *without imparting to these their characteristic odour.* The refrigerators are lined with non-absorbent material, such *as zinc or crystopal,* and the internal fittings are removable for cleansing purposes. Crystopal is described as imperishable, damp-proof, and proof also against fluctuations of temperature and against stains. It is a stout, resistant material with a beautiful white glaze and gives a very attractive appearance to the interior of the cold chamber. The refrigerators are made with an inner and an outer case and between the two there is a thick layer of a special non-conducting material made of cork or hair felting submitted to great pressure. *Altogether these refrigerators* are constructed on sound scientific lines, in addition to which *they are designed to comply* with the conditions demanded by hygienic considerations.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 9th, 1829.

Mr. John Crichton communicates a case of "*leaping ague* of Angusshire," a disease which is, at least by that name, new to us. The subject of this singular affection was a young lady, with a bad stomach, who from this cause, from a *fright* by robbers, and the subsequent loss of a sister, became melancholy and dejected. The suppression of the catamenia, accompanied by coldness of the extremities, ensued; the paroxysm usually commenced, by her collecting her trinkets, and taking them into bed, where she amused herself with *them for some time. She next* rose, and what with running over tables, and mounting doors to swing *backwards* and forwards, she was with difficulty restrained from injuring herself; she then became exhausted, and fell into a deep sleep. Her conversation and writing, which she sometimes adopted to make herself understood, were distinguished by the peculiarity of pronouncing the last letter of a word first, and by commencing her manuscript which she wrote from right to left, by the last word of *the sentence intended to be written.* Opium was tried to check these paroxysms, but produced *stupor; and a shower* bath, which was tried once, produced a lock-jaw for some days. The disease, however, never returned with the same violence after its use, and, by a proper attention to the state of the stomach, and a voyage to the Baltic, she became convalescent, and is now entirely restored to health.*

THE LANCET.

LONDON: SATURDAY, MAY 11, 1907.

The Oliver-Sharpey Lectures.

"Whilst knowledge is in the making there must be divergencies of opinion and it is only by a full and free discussion of these and by the renewed research of which criticism is the stimulus that any certainty in the way of truth can be arrived at." With these strikingly apposite remarks Professor W. D. Halliburton introduced the subject matter of his Oliver-Sharpey lectures on New Facts in Relation to the Processes of Nervous Degeneration and Regeneration, delivered before the Royal College of Physicians of London on April 29th and 30th, and published in The Lancet of May 4th (p. 1207) and 11th (p. 1273). About many of the details of both of these processes there has been, and still is, much controversy, and the new facts brought forward by Professor Halliburton and his co-workers are, in the main, the outcome of critical experiments specifically devised to put to the test matters in dispute and to establish where the truth lies amid conflicting observations and opinions.

His first lecture was almost exclusively devoted to the chemical aspects of nerve degeneration. After referring to the pioneer work of Thudichum in regard to the chemistry of healthy nerve tissues and to the difficulties in the way of research in this field owing to the many gaps in our knowledge, he proceeded to emphasise the importance of the phosphorised fatty constituents, taking lecithin as a type and one convenient for study, since both its composition and the products of its decomposition are known. Lecithin on hydrolysis yields fatty acids, including oleic acid (to which the well-known osmic acid reaction is due), glycero-phosphoric acid, and choline, a nitrogenous base. These decomposition products are of interest in regard to degeneration, since the Marchi reaction, now so generally utilised in demonstrating degenerated nerve fibres, depends upon the fact that the oleic acid resulting from the decomposition of the lecithin is capable of giving the black colouration with osmic acid even in the presence of chromic salts, while lecithin itself does not. Again, Professor Halliburton and Dr. F. W. Mott have shown in a previous research that in degenerative diseases of the nervous system and in degeneration artificially produced in animals by the cutting of nerves, the products of degeneration, notably choline, can be detected in the circulating fluids, and they suggested that the discovery of choline in the blood and cerebro-spinal fluid affords a definite proof of the breaking down of nervous tissue and further that it might be of service in distinguishing between organic and functional disorders. Their conclusions have been confirmed by other observers, but the methods which they proposed for the detection of choline have been criticised. These tests were two in number: first, a chemical test—viz., the preparation of crystals of the double chloride of choline and platinum; and secondly, a physiological test, which consisted in observing the effect of injection into the blood stream, this being a temporary fall of arterial blood pressure which, if the animal has been previously poisoned with atropine, does not occur or is replaced by a rise. It is, however, the chemical test which has been chiefly criticised. It was pointed out by Allen and French that in the preparation of the crystals potassium salts were not entirely eliminated and that these formed a double chloride of platinum and potassium of similar crystalline form to that of choline platino-chloride. These observers, using an iodine test for choline which is not subject to this source of error, confirmed the occurrence of that substance in the blood of patients suffering from acute degeneration of nervous structures. Dr. Otto Rosenheim, working in Professor Halliburton's laboratory, has re-investigated the matter and elaborated three tests for choline, one of which Professor Halliburton regards as simple, easily applied, and absolutely decisive. The method of applying it is to add a strong solution of iodine in potassium iodide to a preparation of the crystals of choline platino-chloride, which then disappear and are replaced by dark brown plates and prisms not unlike hæmin crystals. They consist of a periodide of choline and are very unstable, being rapidly converted into brown oily droplets if the slide is allowed to stand so that the liquid evaporates, while if more iodine solution is added they once more form and again disappear. Donath in Germany has brought forward another means of distinguishing the crystals of choline platino-chloride from those of the potassium salt by showing that the former are doubly refractive while the *latter are not*. Further research by Dr. Rosenheim has brought to light the occurrence of other organic substances in the blood and cerebro-spinal fluid in cases of breaking down of nervous tissues and has also shown that to obtain the iodine test for choline it is not necessary to prepare the platino-chloride, since it can be applied directly to the alcoholic extract of the cerebro-spinal fluid. In regard to the physiological test for choline further investigation has demonstrated that other substances exist in extracts of nervous tissues which exert a depressing action on blood pressure, but that this action is not abolished by atropinisation. An interesting fact observed by Dr. Reid Hunt in America is that an artificial derivative of choline—viz., acetyl-choline—is much more active, being capable of overcoming the effect of adrenalin.

The second lecture is devoted to a histological and experimental examination of certain aspects of the regeneration of nerves. It is a remarkable fact that whereas the original account of the histological changes in degeneration of nerves given by the elder Waller more than 50 years ago has never been assailed, and, indeed, has been but little, if at all, added to, on the other hand, his descriptions of the processes of nerve regeneration have been repeatedly disputed. It is, moreover, a great tribute to the accuracy of his observation that in spite of this his view that the axis cylinder is a branch of a nerve cell, and that in regeneration the restoration of the axis cylinder takes place from the central end of the divided nerve, is now the view held by the majority of observers. The opposing view, that "autogenetic regeneration," or regeneration in the distal end without central outgrowths, occurs was originally brought forward by VULPIAN and PHILLIPEAUX. Many years later VULPIAN, on repeating his experiments, found that his results were to be explained by means of fibres growing into the peripheral stump from other nerves in the neighbourhood, and he therefore recanted his former opinions and adopted the Wallerian explanation. Recently PURVES STEWART and BALLANCE in this country, and BETHE in Germany, have revived the autogenetic theory, the former as the result of histological observations, and the latter on histological and experimental grounds. These views have been strenuously controverted by LANGLEY and ANDERSON, by LUGARO, by RAMON Y CAJAL, by MARINESCO, and by Professor HALLIBURTON, Dr. F. W. MOTT, and Mr. A. EDMUNDS, while in a recent paper even BETHE himself admits that in adult animals no regeneration of medullated fibres occurs autogenetically. Professor HALLIBURTON and his co-workers have arrived at conclusions similar to those reached 15 years ago by HOWELL and HUBER and in consonance with the original views of WALLER—viz., that "although the peripheral structures are active in preparing the scaffolding the axis cylinder which is the essential portion of a nerve fibre has an exclusively central origin." The experiments described by Professor HALLIBURTON, which comprise both histological and experimental methods, were ingeniously conceived and admirably adapted to set at rest the matters in dispute. They find that the neurilemmal cells show changes both in regard to degeneration and *regeneration*; at an early stage of the former process their nuclei multiply; later together with phagocytes they take part in the removal of the myelin droplets; subsequently they become, in association with regeneration, elongated and connected end to end, an appearance which has given rise to the supposition that they form the new nerve fibres. To test this a long stretch of sciatic nerve was removed and every precaution was taken to prevent union of the peripheral end with central fibres; it was then found that chains of neurilemmal cells, without any indication of either axis cylinder or medullary sheath, were all that could be observed in the peripheral stump, which was, moreover, inexcitable to strong faradic stimulation. The next group of experiments was carried out upon transplanted nerves and when precautions were taken to prevent the ingrowth into them of fibres from the central ends of nerves cut through in the operation similar results were obtained. At the suggestion of Professor F. GOTCH experiments were made on the degeneration of regenerated nerves which were found to degenerate towards the periphery after a second section below the site of the original lesion, a result much more in agreement with the view that regeneration occurs from the centre towards the periphery than with the autogenetic theory. This view was likewise supported by observations on the process of medullation of regenerating nerves, which is found to be more advanced near the place where the nerve was originally cut than at more distal situations—a very significant piece of evidence. The result as a whole has been to establish the Wallerian view of the process of regeneration and to clear up some obscure points in regard to this important practical question. Professor HALLIBURTON's two lectures constitute a valuable addition to the science of applied physiology and are worthy of careful study not only by physiologists but also by those engaged in the actual practice of medicine and surgery.

◆

Experimental Anæsthesia.

THE problem of anæsthesia is one of the most interesting that can engage the attention of physiologists or clinicians and we are glad to indicate briefly to our readers some of the points recently investigated by Dr. G. A. BUCKMASTER and Mr. J. A. GARDNER and described by them in several papers read before the Royal Society. We mean by "the problem of anæsthesia" the question of what exactly happens to an anæsthetic vapour after it reaches the lungs, in what form it exists in the blood, how it is held there, how given up to the tissue cells, and in what way it exerts upon them its peculiar and possibly selective action. These questions are difficult factors in the problem, but they hold in their answers our power to perfect in the future the practical art of administration of anæsthetics until danger is even further banished than at present, and until the subsequent discomforts to the subjects which are now the more general reproach of anæsthesia cease altogether. Numerous observations and experiments have been made, both in this country and abroad, with the view of determining the proportion of the inhaled chloroform which is retained by the patient, the amount of chloroform present in the blood of an animal fully anæsthetised and of one killed by chloroform, and the manner in which chloroform is associated with shed blood when this is exposed to chloroform vapour outside the body It is with regard to the last matter especially that the experiments of Dr. BUCKMASTER and Mr. GARDNER are valuable, as their work was directed particularly towards throwing light upon the rate of assumption of chloroform by circulating blood, the actual vehicle in blood which is concerned in the transport of this drug, and the relative danger of the various degrees of anæsthesia.

In the first place the observers made a number of experiments to determine the anæsthetic and the lethal quantities of chloroform in the blood of animals; and in the second place, they attempted to ascertain how chloroform is distributed between the corpuscles and the plasma of the blood. The latter experiments go over ground that is new or has only recently been trodden. The conclusion arrived at as to the distribution of chloroform in the blood is, broadly speaking, that the main bulk of the drug is held by the red corpuscles and very little indeed by the plasma. In the case of cats this is so unless narcosis is of an extreme degree or very rapidly induced. In connexion with this fact—for a fact we may now reasonably take it to be—we may remark upon the statement of the authors that the oxygen-carrying power of the hæmoglobin is in no way interfered with, an opinion which is opposed to that previously expressed by other observers. But it is interesting to notice that Dr. BUCKMASTER and Mr. GARDNER found no evidence of the decomposition of chloroform within the blood. This is contrary to the finding of DESGREZ and NICLOUX who held that as much as 6·9 cubic centimetres of carbon monoxide, the result of chloroform decomposition, may appear in 1000 grammes of blood during profound chloroform narcosis. Certainly, the experiments of the more recent observers seem to prove that none of the hæmoglobin of a chloroformed animal is in the state of CO-hæmoglobin. Yet the colour of the blood itself is a good guide to the degree of anæsthesia in a chloroformed animal. It appears that in the case of dogs chloroform enters the plasma rather more readily than is the case with cats. The latter were chosen for the present investigation because their behaviour towards anæsthetics is more comparable with that of the human subject. Whatever be the exact character of the association between the chloroform in an anæsthetised animal and the corpuscles of the animal's blood one fact about it is certain—namely, the firmness of the association. There is no smell of chloroform to be detected in samples of such blood, and if samples are allowed to stand for a night they suffer no diminution in chlorine, showing presumably no diminution in the chloroform which the blood holds. Another feature of the relation of chloroform to the blood of an animal which is killed by the anæsthetic is its bearing upon medico-legal inquiries. This is the great diminution of chloroform in the blood that is observed shortly before death. The explanation preferred for this phenomenon is that an abnormal quantity is at this time to be found in the tissues themselves, particularly the tissues of the nervous system. In animals which are anæsthetised but not killed by chloroform the amount of the drug which enters the central nervous system may equal, but never exceeds, and is generally much less than, the amount in the blood.

From the clinical point of view we may notice in these physiological observations one or two points which are in harmony with our preconceived notions. There are necessarily differences between the conditions which obtain in the physiological laboratory and the operating theatre, and a recognition of this fact explains apparent discrepancies between physiological experiments and clinical observation. In the one case almost absolute control can be obtained over the environing circumstances of the administration of the anæsthetic; in the other this is impossible—at least, in many cases. That the conclusions arrived at by experiment are wholly true when applied to clinical ends there can be no doubt; and they further lead the clinician to modify his methods in such ways as will enable him to produce results parallel with those obtained in the laboratory. It is from this point of view that the work of such investigators as Dr. BUCKMASTER and Mr. GARDNER stands out as of conspicuous value to the practitioner of medicine. To take an example. In the ordinary methods of inhalation as conducted in the clinical theatre there is a much greater chance of mechanical obstruction to breathing than when the chloroform is aspirated directly through a tracheal tube, as in the case of the physiological experiment. Again, the so-called "idiosyncrasy" which has been assumed to exist in certain persons with regard to anæsthetics becomes intelligible if the physiologist's conclusion is correct that there is no absolute relation between the proportion of chloroform in the blood and the effects of the drug upon the entire organism, for these are determined not by the amount of chloroform present in the circulation but by the quantity which enters the tissues of the central nervous system. Obviously, therefore, to any two individuals A and B the same amount of the drug might be offered for inhalation, the same amount might be inhaled, the same amount might be present in the blood, and yet the central nervous system of A might have enough chloroform to produce anæsthesia, while that of B might be only affected to the degree of arousing some slight excitement. Another highly important conclusion which tallies with clinical experience is the statement that the amount of chloroform in the blood which produces anæsthesia varies with the rate of induction of anæsthesia. This is to say, that roughly speaking the more gradually the patient is anæsthetised with chloroform the less of the drug will he have to inhale from first to last. This fact is one of the chief arguments in support of those chloroform-regulating forms of apparatus by which it is possible to give extremely low percentages of chloroform vapour and to control the percentage inhaled throughout the whole course of the narcosis. Yet it is important that the administrator should bear in mind the conclusions which show with what minute quantities of chloroform anæsthesia may be maintained, and for this reason we have drawn attention to the point. The methods described in these researches for the estimation of chloroform in the blood are novel and practically free from error. They would appear to be capable of giving more trustworthy results than those employed previously by SCHMIEDEBERG and POHL and to supply figures more accurate than those recently obtained by French observers. Dr. BUCKMASTER and Mr. GARDNER refer to experiments to be described in the future bearing upon the production of anæsthesia under varying conditions, and we hope to revert later to their valuable and suggestive investigations.

Medical Men and Workmen's Compensation.

SOME six months ago Mr. ALBERT BENTHALL, who has given much attention to the medical questions connected with the various forms of insurance, called attention in our columns to the pronounced manner in which the Workmen's Compensation Act, 1906, would affect medical practitioners. As all our readers know, the Act at present in force, a piece of legislation dating from but nine years ago, contains a number of conditions which have proved fruitful sources of litigation. The "workman" to be assisted by the moribund Act is limited by definition and the circumstances in which he can claim compensation are detailed and particular, but by the Act which will come into force on July 1st next all these conditions and limitations will be swept away. Under Clause 13 of this Act the "workman" is defined in the following words:—

"'Workman' does not include any person employed otherwise than by way of manual labour whose remuneration exceeds £250 a year, or a person whose employment is of a casual nature and who is employed otherwise than for the purposes of the employer's trade or business, or a member of a police force, or an outworker, or a member of the employer's family dwelling in his house, but, save as aforesaid, means any person who has entered into or works under a contract of service or apprenticeship with an employer, whether by way of manual labour, clerical work, or otherwise, and whether the contract is expressed or implied, is oral or in writing."

From this definition of "workman" it will be seen that medical men are especially concerned in the working of the new Act, for many medical practitioners necessarily employ in addition to general domestic servants an assistant or dispenser, a locum-tenent, a coachman or chauffeur or both, and may also have to employ a surgery boy and other dependents whose occupation may or may not come under the head of casual work. In the event of a fatal accident happening to any of these "workmen" in the course of their duties the employers will be liable, if the employees have any dependents, to pay to these dependents perhaps as much as £300 in compensation, the legal liability being for a sum equal to three years' wages, or £150, whichever of these sums is larger, providing that the payment does not exceed £300. But the death of an employee is not so much to be feared as his or her disablement from accident, for here a weekly payment during the continuance of the disablement will have to be paid, which might conceivably mean an annuity by the side of which any lump sum payable in case of death might be a comparatively small amount. From these circumstances, all of which have been brought prominently before our readers in our editorial columns during the past six months, it will be seen that a very large number of medical men will have to insure against their new risks unless they are willing to take the chance of being heavily mulcted by fortune.

As an outcome of this feeling a Medical Insurance Committee was formed early this year to consider whether it would not be possible to devise a scheme for combination in insurance whereby medical men, who must in the future become the payers of increased annual sums in premiums, could benefit from some coöperative scheme ensuring to them a substantial rebate. The Medical Insurance Committee as originally constituted consisted of representatives of the *British Medical Journal*, THE LANCET, Dr. H. Radcliffe Crocker (who accepted the invitation to become chairman), Dr. J. A. Macdonald, Mr. George Eastes, Mr. Albert Benthall, Dr. T. H. Arnold Chaplin, Mr. J. Smith Whitaker, and Mr. Guy Elliston, secretary of the British Medical Association, and after considerable deliberation, in which the exact position of the Association towards the scheme was arrived at, it was settled that the committee should arrange to conduct an agency for insurance against accident and other risks on behalf of medical men, the usual agency commission being used for defraying clerical labour and for benevolent purposes for the benefit of the insurers. The committee sat frequently and received particulars of agency commission and rates of premium from a number of insurance companies and is now in the position to recommend the proposals made to it by the Guardian Assurance Company, Limited, against risks arising under the Workmen's Compensation Acts, as well as in respect to fire, burglary, and accident to the insurer. An advertisement giving full particulars with regard to the arrangements of the Medical Insurance Committee with the Guardian Insurance Company, as well as the rates of premium and form of proposal to be addressed to the committee, will be found on page 19 of our advertisements this week. On the lower part of the form being detached and forwarded to the Medical Insurance Committee, care of the British Medical Association, 6, Catherine-street, Strand, London, it will receive prompt attention, while any further information that may be required will be supplied by the committee. Our advice is that, in cases where there seems doubt whether an employee comes within the scope of the Act, the small premium to cover insurance should be paid willingly, at any rate until legal proceedings under the Act have led to certainty as to the interpretation of its provisions. It will be open to any employee who can find a solicitor to assist him to bring an action against his employer for compensation under the Act. Although the employer may win the case he will have to meet his legal expenses unless he is insured. Insurance carries such expenses.

The scheme is simple in its nature and should be comprehensible, we think, without any trouble. The Medical Insurance Committee has established an agency for insurance against risks arising under the new Workmen's Compensation Act, the scheme also taking cognisance of all risks of the employer for compensation to his employees at common law, as well as the risks of fire, burglary, and accident to the insurer. The agency will allow a discount of 10 per cent. to the insurer upon his premiums save in the case of fire, and here the rebate is not offered by the Guardian Insurance Company; but we understand that the principal insurance offices are unanimous in deciding that no discount for premiums can be allowed to an insurer in respect of fire, a solidity of opinion that is probably dictated by the relations of the various offices to their regular agents. In proportion to the extent to which this scheme meets with the general support of the medical profession there will be left, after allowing the discount and paying expenses, a large or a small annual sum in the hands of the Medical Insurance Committee to be disposed of for the benefit of the insured. The scheme provides that this sum shall be devoted to benevolent purposes, and it will presumably be expended for the benefit of any persons insuring through the Medical Insurance Committee who are incapacitated from work by age or disease or who are in poverty. Those widows or orphans of the insured whose pecuniary resources are particularly slender will probably receive the earliest attention of the committee.

Annotations.

"Ne quid nimis."

THE CONTROL OF MALARIA IN INDIA BY THE ITALIAN METHOD OF LAND IRRIGATION AND SILT-BUILDING.

An interesting paper on the "Applicability to India of the Italian Method of Utilising Silt" was read before the Indian section of the Society of Arts on May 2nd by Sir Edward Buck, K.C.S.I., who has already made a report on the subject to the Governor-General of India in Council. Since the twelfth century the Italian agriculturists have been accustomed to carry on engineering works for the control of their natural water-supplies as well as for agricultural purposes, and these Professor Nicoli of Pisa (quoted by Sir Edward Buck) has summarised as follows: (1)

irrigation, or the supply of water to crops; (2) fertilisation of land by irrigation and (3) by submersion; (4) protection against frost by submersion; (5) *bonificazione* in the plains; and (6) *bonificazione* in the hills. Sir Edward Buck finds it impossible to translate *bonificazione* into one English word and thus expands its meaning, "The fertilisation and sanitation of low-lying unhealthy lands in the plains by deposit of silt combined with drainage; and in the hills the utilisation of silt and the prevention of erosion"; and his communication to the Society of Arts might have been called the Gospel of Silt with the text, "That wherever fertilising silt is available it is a grave economical error not to profit by it." Most instructive figures and details were given in support of this proposition, the average increase in the value of land on which mountain waters have been allowed to settle and deposit their silt being 20 per cent. at a low estimate. The value of a system of damming watersheds to obtain collections of alluvial deposit was fully recognised by the great engineer, architect, and painter Leonardo da Vinci, who in his treatise on the "Movement and Measurement of Waters" heads his fifty-third chapter, "How with the running waters we ought to carry the earth of the mountains into the valleys, so as to render them fertile, and to purify the air;" and that his counsels have been followed by his countrymen Sir Edward Buck testified in these words: "And for the last five centuries the intelligence of the Italian engineers has been directed to forcing each stream to turn the swamps which it had itself caused into fertile plains, and to build up with its own silt rich terraces in the very ravines which it had torn from the hillsides." It will be seen that Leonardo da Vinci's heading indicates something more than a merely financial advantage to be derived from these measures, and for centuries it has been recognised that silting and draining operations invariably coincided with improved health in the local communities; in fact, although until quite recently no adequate reason could be given, they were known certainly to abate the incidence of malaria in the districts where they were employed. Sir Edward Buck points out that the work of *bonificazione* is very much on all fours with the proceedings which modern medical discovery would recommend as necessary for the extermination of malaria by the destruction of the breeding-places of the mosquito; and in his opinion there is not only no reason why malaria should not be entirely stamped out of Italy, if the Government of that country continues to work on the present splendid scale for the agricultural benefit of the country, but there is reason to hope that similar methods adopted in India would succeed from both economical and hygienic standpoints. That they may succeed locally is already proved by the increased value of estates which have adopted methods allied to *bonificazione*, but the question of carrying them out throughout India at the Government expense is one that must needs be thoroughly considered by competent engineering, agricultural, and sanitary experts. In this connexion Sir Edward Buck pleads for the training of a number of "agricultural engineers" who could apply their whole energies to the practical solution of the problem in different localities and the preparation of special survey maps with the same object. Sir Edward Buck's report to the Governor-General of India in Council as to how far the methods of *bonificazione* might be adopted with advantage in India gives a very careful analysis of the scheme and the importance of such a movement can hardly be over-estimated if it be economically feasible. Not only would the abolition of malaria render the lives of both Europeans and natives in India—where "a touch of fever" is about as common as is "a cold" with us—infinitely more comfortable, but it would proportionately enhance the working value of that complex administrative machinery on which the welfare of the country depends. It is gratifying to hear from Sir Edward Buck that his report was in great part due to Lord Minto's personal interest in the matter.

THE "VACCINATION ACT, 1907."

ON April 30th Mr. John Burns introduced into the House of Commons a Bill to substitute a statutory declaration for the certificate required under Section 2 of the Vaccination Act, 1898, of conscientious objection. The Bill is very short and its principle is contained in Section 1 of Clause 1, which runs as follows:—

> 1. No parent or other person shall be liable to any penalty under Section 29 or Section 31 of the Vaccination Act, 1867, if within four months from the birth of the child he makes a statutory declaration that he conscientiously believes that vaccination would be prejudicial to the health of the child and within seven days thereafter delivers the declaration to the vaccination officer of the district.

If Mr. Burns fancies that by this Bill he will soften the manners of Mr. Lupton and his fellow antivaccinationists and not allow them to be ferocious we fear he will meet with disappointment. Dr. W. R. Hadwen has already written to a morning contemporary stating that the Bill can only be accepted by antivaccinationists as an instalment. Vaccination, of course, in the eyes of a certain class of mind is responsible for nearly all the evils in the world, and a study of antivaccination literature makes the reader think that those who write it look upon Jenner's discovery in the same manner as our forefathers did upon Napoleon in the early days of the nineteenth century. The question "Who fills the butchers' shops with large blue flies?" is ever on their lips, the answer being "vaccination!"

AN OUTBREAK OF FOOD POISONING.

WE have received a copy of a report prepared by Mr. William Berry, medical officer of health of the county borough of Wigan, on an outbreak of poisoning due to potted tongues sold for food at the Market Hall, Wigan, on Jan. 11th and 12th. So far as could be determined, 188 cases in 60 different houses came under the observation of medical practitioners in Wigan, Adlington, Ince, Platt Bridge, Skelmersdale, and Standish, but it is probable that there were in addition mild cases to which no medical aid was summoned. The first cases reported to the health department were due to some of the tongue bought on Jan. 12th and eaten that same night, the first symptoms appearing early on the morning of the 14th, 36 hours afterwards. The symptoms were severe and lasted for three or four days, recovery occurring in all of them. On investigation it was found that all the cases could be referred to the one source and, further, that every person who had partaken of this particular food was attacked with symptoms of food poisoning of greater or less severity. The butcher's stall and shop were at once visited, a thorough inspection was made, and the remains of the unsold tongue, then becoming putrid, were taken possession of. Investigation showed that the particular tongues (pigs' and beef) were placed in brine on Thursday and Saturday (Jan. 3rd and 5th). They remained in it for three or four days, were taken out on Tuesday (Jan. 8th), boiled on Wednesday, and taken to the market on Thursday to be ready for sale on Friday, Jan. 11th. Two tins of beef tongue, each weighing about 20 pounds, and one tin of pig's tongue, weighing about 12 pounds, were made and exposed for sale. The examination of the usual methods of procedure showed that in addition briskets of beef are prepared in a similar manner by this butcher. The beef and the beef tongues are bought at Birkenhead, but the pigs which come from Ireland are slaughtered on the premises of the butcher. There are five brine tubs, kept in a cellar under the fish market, where are stored also hams and sides of bacon for salting. One of these barrels is used for brisket of beef for preparing "pressed pickled beef," two are used for pigs' heads, and one small one for pigs' and beef tongues. The brine is prepared by taking two buckets of salt, six buckets of water, three-quarters of a pound of saltpetre, and half a handful of sugar. The cooking is carried out in pans at the slaughter-house and examination of these showed them to be clean. After boiling the tongues are taken out, placed in tin and mug receptacles, pressed slightly, and then allowed to cool. After cooling they are again pressed and hot jelly, prepared from pigs' heads, is poured on. To discover the origin of the contamination of the tongues sold on this occasion Mr. Berry took samples of salt and freshly made brine, some freshly salted pigs' and beef tongue, and one pig's and one beef tongue after salting and cooking, together with the remainder of the tongues causing the symptoms of poisoning, and submitted them for examination to Dr. W. B. Warrington at the Pathological Department of the University of Liverpool. The salt, saltpetre, and specially cooked tongues were found to be free from bacillus coli communis or bacillus enteritidis (Gaertner). In the salted uncooked tongues bacillus coli communis was isolated from the pig's tongue and a somewhat similar but not identical organism from the beef tongue, while in the tongue to which the outbreak was due both bacillus coli, or an organism similar to it, and bacillus enteritidis of Gaertner were found. Mr. Berry therefore concludes that the cause of the mischief has been the brine in which the tongues were placed before cooking, but unfortunately the brine used on this occasion was thrown away and could not therefore be examined bacteriologically. He recommends that in all cases where salting has to be done fresh brine should be used for each batch and no additions should be made to it after the tongues or other meat have been put in. This seems certainly a reasonable precaution but in addition means should be taken to prevent the salting of contaminated material, since doubtless if the brine were the cause of the infection of the particular tongues it must have itself become infected from some other source, probably infected meat. The long incubation in these cases before symptoms supervened demonstrates that this outbreak was probably due to the bacillus enteritidis and its toxins rather than to ptomaine poisoning in the strict sense of the word, and since the toxins of bacillus enteritidis and some of the other organisms responsible for food poisoning are not destroyed by boiling even for half an hour, the only effective prophylaxis against outbreaks such as the present must be a more careful examination of the origin of meat offered for human consumption.

THE PHYSICIAN'S HOLIDAY.

"IT is your genuine worker," writes an Italian contributor, "who really enjoys a holiday; nay, more, who can make that holiday an occasion of enriching other fields of knowledge or culture outside his own. The science, the literature, the fine art of previous generations teem with instances of such employment of well-earned leisure—instances, moreover, in which the medical man appears to exceptional advantage: Italy, in the day now passing, supplies us with one of these in the indefatigable professor of physiology at Turin, Dr. Angelo Mosso, who is employing a temporary leave of absence from the laboratory and the lecture-room in prehistoric research in Sicily, where, in the province of Girgenti, he has found a 'pleasant pastime' in unearthing a neolithic village. Cannatello, the village in question, has yielded to his well-inspired 'spade work' quite a fund of treasure-trove, besides disclosing a 'piazza circolare' which he describes as an 'absolute novelty' in the neolithic architecture of Southern Italy—the said 'piazza' being well paved and presenting five cabins built with great blocks of stone. Other cabins in the villages are, he says, wonderfully conserved, and demonstrate the tectonic ability of their neolithic builders, while the pavement of the intersecting streets contains fragments of straw recalling the 'technique' of similar work in Troy. 'Tables of libation' he also found, showing intercourse with Crete, confirmed by other finds in votive offerings, and 'astragali.' A tomb excavated by him at Sant' Angelo Múxaro contained 45 vases quite entire and without a flaw, and these he has made over to the museum at Palermo. Although this tomb may be assigned to the last centuries preceding the Hellenic invasion the vases found in it indicate by their decoration a yet remoter epoch, their ribbons and cords resembling those of the 'epoca neopatica' of Central Europe. To the 'vasi di steatite' Professor Mosso attaches special importance as substantiating the prehistoric relations of Crete with Sicily. Other details hardly less striking are given in the special report which he has just sent to the Minister of Public Instruction, to whose department all excavation work in Italy belongs, and the elaborate monograph in which the results of his 'archæological holiday' will ere long be embodied is, I need hardly say, awaited with interest wherever prehistoric research is held in honour. Professor Mosso's latest utilisation of 'well-earned leisure' has often had its counterpart in the British Isles and would have greatly impressed such men as Dr. James Cowles Prichard of Bristol and Sir J. Y. Simpson of Edinburgh, whose 'recreation' from professional work lay in similar research. It was in exploring and illustrating for his contemporaries the old site of Pompeii and Herculaneum that Dr. Hughes Bennett, himself like Dr. Mosso a professor of physiology, found congenial distraction, and in the "sixties" of the last century Dr. King Chambers enriched THE LANCET with his impressions, antiquarian and other, of the Italian kingdom, afterwards published in a volume still highly esteemed. Germany, too, can point to the salutary results of the 'physician's holiday' in the incomparable guide to Italy of Dr. Gsell-Fels—a work which the English historian Freeman assured me was of the greatest service to him in preparing his monumental book on Sicily, a work, moreover, which the late Camden professor of ancient history at Oxford, as I can testify, used to excellent purpose in preparing his lectures and which he often quoted to me as an example of how history and archæology could be made to profit by an accomplished 'physician on his holiday.'"

THE COAGULATION OF BLOOD AND THE EFFECTS OF CERTAIN DRUGS AND TOXINS UPON IT.

IN an article with the above heading, published in the April number of the *Bio-chemical Journal* (vol. ii., No. 4, 1907), Dr. C. J. Coleman gives the results of his recent investigations. The influence of fluids containing solutions of salts or drugs injected subcutaneously upon the rapidity with which coagulation of the blood takes place is more difficult to determine than might at first sight appear. In the first place the time is not the same in different individuals. It is not the same even in the same person at different times of the day, the longest coagulation time occurring about one hour after the principal meals, which is probably attributable to the changes in the blood effected by absorption of the products of digestion, whilst on the contrary the shortest time is recorded when the subject is fasting before breakfast. Then, again, the influence of exercise and of temperature must be taken into consideration, 15 or 20 minutes of severe physical exertion or a slight rise in temperature appearing to effect a certain amount of shortening of the coagulation time. Lastly, it was found that the method employed or the instruments used for the abstraction of the blood were of importance in the determination of the time. The method employed by Dr. Coleman was to shave and to cleanse the ear of rabbits and to obtain a specimen of blood by pricking the marginal vein. Then the animal being kept fasting to set aside as far as possible the disturbing influence of food a definite quantity of blood was withdrawn, and the time tested either by Brodie and Russell's coagulometer or by Wright's instrument described in our pages,[1] some advantages attaching to each. In experimenting on the influence of drugs or other agents on the coagulation time, therefore, it is important that the same conditions should be preserved as far as practicable. The drugs, it may be remarked, were injected subcutaneously with a hypodermic syringe. The effects of milk were first examined both in suckling and adult animals and it was found in opposition to the observations of Wright and Paramore to have very little, if any, effect in either accelerating or retarding coagulation. In other experiments on rabbits Dr. Coleman found that the administration of citric acid lengthens the time of coagulation by forming sodium citrate. The hypodermic injection of calcium chloride shortens the time of coagulation. Solutions of normal saline injected subcutaneously have a pronounced effect in diminishing the time of coagulability of the blood. The injection of β-naphthylamine lengthens it, due in all probability to the accompanying pyrexia, since the effect is not obtained if the pyretic phenomena are absent, as is occasionally observed. The subcutaneous injection of diphtheria toxins augments the time of coagulation. Finally, it was found that when leucocytosis occurs either as the result of some pathological condition or of the hypodermic injection of a drug there is a lengthening of the time of coagulation of the blood.

IS CHICORY INJURIOUS?

THE above may seem a startling question to ask, for chicory has been abundantly mixed with coffee for a great many years and we cannot recall a single instance in proceedings taken under the Sale of Food and Drugs Act in which it was urged that chicory was injurious. When a mixture of coffee and chicory is sold as coffee an offence is, of course, committed in accordance with the terms of Section 6 of the Act, which requires that no person shall sell to the prejudice of the purchaser any article of food which is not of the nature, substance, and quality demanded by the purchaser. On the other hand, if it can be shown that chicory is injurious to health it is clear that the proceedings could be based on Section 3 of the Act which demands that no person shall mix, colour, stain, or powder any article of food with any ingredient or material so as to render the article injurious to health. During the hearing of an action for slander, which was decided in favour of the plaintiff in the High Court last week, one witness stated that the selling of 50 per cent. chicory and coffee mixture was likely to cause a great deal of disease in a poor neighbourhood, and a medical man also stated that from his medical experience in poor districts coffee mixed with chicory often set up irritant poisoning. Mr. Justice Bigham admitted some interest in this statement, since he said he had been in the habit for many years of drinking a mixture of chicory and coffee. The chemistry of chicory does not appear to be as clear as it might be. We are merely told that it contains some volatile oil, a bitter substance, and a large proportion of carmel. It answers the purpose of the substitution-monger admirably in giving intensity of colour to coffee infusion, rendering it fuller flavoured than when coffee is used alone. The introduction of chicory for this purpose did much to diminish the popularity of coffee in this country. The consumption of coffee may have fallen owing possibly to the flavour of chicory being disliked or there may have been a real dietetic reason and some persons may have found that chicory disagreed with them. Against this view, however, is the fact that in some parts of the continent an infusion of chicory is drunk pure and apparently without prejudicial effects. Most dietetic authorities seem to agree that there is no reason for believing that chicory is in any way injurious to health, and after all it is merely the root of a wild endive, kiln-dried, and broken in fragments. Still, many roots contain injurious substances and the subject seems to call for more serious investigation than it has hitherto appeared to receive.

THE SIXTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

AT the Fifteenth International Congress of Medicine held in Lisbon in 1906 it was decided that the next meeting of the congress should be in Budapest, the capital of Hungary. It is now announced that the Sixteenth Congress will be opened in Budapest on August 29th, 1909, and that it will continue to Sept. 4th. The work of the meetings will be conducted in 21 sections. Professor Calman Müller is the president and Professor Emil Grósz is the general secretary. The offices of the various committees in charge of the arrangements are at Esterházy-utcza 7, Budapest VIII.

TRAUMATIC ASPHYXIA.

TRAUMATIC asphyxia (asphyxia due to pressure on the chest) is a rare condition which has seldom been studied during life. Our knowledge of it has principally been gained from examination of the bodies of persons pressed to death in struggling crowds. Many of the occasions on which this accident has occurred are historical. At the Champs de Mars in 1837 23 persons were crushed to death in the rush of the mob; in the fire at the Vienna Ring Theatre nearly 1000 persons perished in this way; and in the panic at the Victoria Hall, Sunderland, 200 children were asphyxiated by being crushed in a corridor. In the *Canadian Medical Journal* for April Dr. E. S. Ryerson has reported the following case. A boy, aged five years, was admitted into hospital on May 9th, 1906, for injuries which he had received about an hour previously while riding on the back of a lorry. In some way he was caught between the hind wheel and the spring, stopping the wheel and making it drag along the ground for some feet and thus attracting the driver's attention. He was picked up unconscious, black in the face, and breathing with difficulty. On admission there were marked symptoms of shock; he was cold and shivering and his teeth chattered; his face was pallid and his pulse was weak and rapid. Consciousness was dulled but questions roused him. His eyes were tightly closed as if he suffered from photophobia. On the head, trunk, and limbs were contusions and abrasions. His face and neck presented a deep blue mottled appearance which shaded off and disappeared over the upper chest. The pallor of the face could be seen through the blue discolouration. The dark blue spots were small and circular and separated by bands of normal skin. They were not influenced by pressure. On the face and neck they were so close together that they resembled a diffuse ecchymosis. In the clavicular regions they were separated by larger areas of normal skin and followed the distribution of the vessels. The eyelids were blue and swollen and could be opened only by force. The conjunctivæ projected over the corneæ from hæmorrhagic effusion beneath them. The respirations were regular but shallow. The heart sounds were irregular but moderately strong. On the 10th he was quite conscious but drowsy; the temperature was 99° F., the pulse was 120, and the respirations were 30. The eyes were still kept closed. The pallor had disappeared and the blueness was not so deep. On the 11th he was bright and sitting up in bed. The blue spots had faded considerably; the conjunctivæ were almost black. Some blue spots were found on the soft palate. On the 23rd he was running about the ward. All discolouration had disappeared from the face and neck and the colour of the subconjunctival hæmorrhage was less marked. The question of the cause of the blue discolouration, which has been termed "the ecchymotic mask," is interesting. In this case it could not have been due to cyanosis because it did not disappear on pressure and because there were bands of normal skin between the discoloured areas. Was it due to hæmorrhage? The conjunctival discolouration undoubtedly was and hæmorrhages or ecchymoses undoubtedly may occur in traumatic asphyxia. But the fact that the colour disappeared without the changes occurring which extravasated blood undergoes is opposed to this view. Ollivier suggested that such discolouration is due to stasis of carbonised blood in dilated and temporarily paralysed capillaries. This was verified by Beach and Cobb of Boston, who excised portions of discoloured skin and examined them microscopically.[1] Every section showed normal skin with enormous distension of the small veins and capillaries. As to the mechanism of production, forcible compression of the chest and abdomen appears to cause a reflux of blood through the jugular veins, which are more feebly protected by valves than the veins of the limbs. This leads to distension of the small veins and capillaries.

SHOP ASSISTANTS AND LIVING IN.

A MEETING of shop assistants recently convened in the City by the National Union of Shop Assistants, Warehousemen, and Clerks was largely attended and considerable interest was shown in the proceedings by those present. The immediate object of the meeting was to protest against a statement made at the Drapers' Chamber of Trade to the effect that assertions with regard to what is known as the "living-in" system put forward at a recent conference of shop assistants at Leeds were untrue and exaggerated. A resolution was carried at the meeting in the City referred to—

> That this meeting of shop assistants, warehousemen, and clerks of the City of London protests against the continuation of the living-in system as being detrimental to the moral, physical, and intellectual development of the employees; and further, calls upon the Government to include workers in the distributive trade in the Truck Acts.

It will be seen from this that the total abolition, not the regulation, of "living in" was the end proposed to, and approved of by, the meeting as desirable, the ambitions of the shop assistants being defined by a speaker as including "the right to say where they should lodge, what they should eat, when they should go in, and when they should go out." On the other hand, the present conditions were denounced as leading in some instances to the assistants "sleeping in rabbit-hutches and eating food which even a dock labourer would turn up his nose at." We suggest that the shop assistants and those interested in their welfare should concentrate their attack upon the sanitary defects of a system which has something to be said in its favour as well as against it, and should aim at securing by stringent regulations and their enforcement wholesome sleeping quarters and food together with reasonable liberty for those who now are deprived of them. They would be on safer ground in doing this than in demanding freedom to go in and out at night absolutely uncontrolled for young men and young women seeking to escape from restrictions which, although irksome, may be salutary. These young people are drawn from a very large and mixed class. Some of them go into "business" in preference to "service," and are more able, perhaps, to look after themselves than those of their companions who have been more gently nurtured. The supply of shop assistants is now so large that the employers evidently can impose their own conditions. On the other hand, the advertisements in daily and weekly newspapers are eloquent as to the lack of candidates for domestic service and the crowd of foreigners occupying situations as men servants tells a similar tale. Employers of both classes should find no sympathy on it being proved that they fail to provide adequate food and living accommodation for those dependent upon them, or that they curtail their liberty to such an extent as to injure their health, or even to deprive them of reasonable enjoyment. Employers may, however, be excused if they wish to exercise some supervision and control over the lives of those who work for them beyond the duration of the working day, and none the less so because an economy is effected by providing board and lodging upon a more or less large scale.

THE PREPARATION AND STRENGTH OF GREY OIL.

IN the *Journal de Pharmacie et de Chimie* of March 16th M. Camille Pépin draws attention to the great number of formulæ that are used for the preparation of grey oil for injection. As a result the products differ widely in consistence and in strength. Grey oil should be of such a consistence that it does not yield a deposit of mercury, and it should melt readily on the application of moderate heat when required for injection. M. Pépin recommends the following procedure in preparing grey oil. Hard and liquid paraffins are mixed by melting them together, the proportions being so adjusted that the product, when triturated with the mercury, does not separate on standing. As regards the strength of grey oil considerable variations exist owing partly to the fact that some operators calculate the percentage of mercury by weight and others by volume. As the oil is always injected by means of a graduated syringe it is preferable to adopt as a standard strength a known percentage of mercury by weight in volume. A strength of 0·2 gramme of mercury in one cubic centimetre of the oil is very convenient. With such a preparation and a Pravaz syringe graduated with 20 divisions to one cubic centimetre an accurate dose can be given, as each division represents one centigramme of mercury. The largest dose of mercury which is injected in practice is 0·14 gramme and this dose is contained in less than three-fourths of a cubic centimetre of the oil. It is very necessary that there should be uniformity in the preparation of so potent a remedy as grey oil. It is highly probable that the mishaps which have attended its use have been due, in some cases at least, to a confusion as regards the dose of mercury through the preparation of the oil by weight and its subsequent administration by volume.

THE DISTRIBUTION OF THE TWO SPECIES OF BED BUG.

SOME knowledge of entomology is rapidly becoming a necessity for medical men practising in tropical or subtropical countries on account of the important part played by numerous insects in the causation of chronic and fatal diseases. Malaria, yellow fever, plague, sleeping sickness, and several diarrhœal diseases are typical examples of contagions communicable by insects. In the Milroy lectures on kala-azar in Assam, delivered before the Royal College of Physicians of London in February of the present year, Major Leonard Rogers, I.M.S., professor of pathology in the Medical College, Calcutta, brought forward evidence tending to show that the disease was spread by the bites of bed bugs,[1] and Captain W. S. Patton, I.M.S., of the King Institute, Madras, has published an article on the nomenclature of these insects in the *Indian Medical Gazette* for February, 1907. Captain Patton states that two species of these insects, known, however, under a variety of names, are associated with man. One of these, the commonly accepted name of which is cimex lectularius (L.), is distributed throughout Europe and North America. The other is the Indian bed bug which is distributed throughout India, Burma, Assam, the Malay peninsula, Aden, and the islands of Mauritius and Réunion. This insect was described in 1852 under the name of cimex rotundatus by M. Signoret who observed it in Réunion. In 1861 it was described as cimex macrocephalus by Fieber who observed it in Burma. Captain Patton has examined a very large collection of this species sent to him by medical officers and others from all parts of India, Burma, Assam, Aden, Mauritius, and Réunion. As they all belonged to one and the same species it is evident that cimex rotundatus and cimex macrocephalus are identical, and Captain Patton therefore proposes naming it cimex rotundatus (Sign.). *Cimex lectularius* (L.), the European bed bug, is also found in the North-West Frontier Province of India.

THE SUPPLY OF PURE MILK TO HOSPITALS.

THE awakening of public interest in the important subject of the milk-supply for children bids fair to rank amongst the foremost achievements of preventive medicine during this first decade of the present century. Not a week passes but the matter is mentioned in some organ of the lay press, and this stirring of the national conscience to a concern for the salvage of its infant life has undoubtedly been caused by the authoritative warning note that is being continuously sounded by the medical profession. We have received from the secretary of the Hospital for Sick Children, Great Ormond-street, the minutes of a conference recently held at that hospital under the presidency of its chairman dealing with this matter: at this conference representatives from the eight London children's hospitals and one general hospital were present. Resolutions were passed, subject to the confirmation of the committees of these various hospitals, embodying the following recommendations:—

1. The milk shall be pure, genuine, and with all its cream as yielded by the cow and absolutely free from any and every kind of adulteration, including preservatives. It shall be of such a quality as will produce at least 3·50 per cent. of butter fat.
2. It shall be supplied from a farm or farms whose name or names and locality are notified to the hospital.
3. It shall be permissible for an authorised representative of the hospital to inspect such farm or farms at any reasonable time.
4. The cows supplying the milk shall be in a good state of health and a veterinary surgeon shall give a certificate to that effect once a quarter.
5. The milk shall be strained and refrigerated at the farm and there canned and sealed.
6. The milk shall be delivered sealed at the hospital.
7. It shall not be "Pasteurised" or treated otherwise than as mentioned in Clause 5 without the written sanction of the hospital authorities.
8. It is advisable that the milk be tested bacteriologically and chemically once a week by the hospital.
9. That the name of the medical officer of health of the district in which a supplying farm is situated be furnished by the contractor and that he be informed of the relations between the farm and the hospitals, and that he and the clerk of the urban or rural district council be supplied by the hospital for their information with a copy of these recommendations.
10. This conference invites the committees of the various hospitals interested to adopt the resolutions passed at this meeting.

This excellent scheme of supply is worthy of all support and we trust the committees of the hospitals concerned will see their way clear to adopt it. There seems no need for its limitation to children's hospitals, for the provision of an undoubtedly pure supply of such an important article of diet as is milk in the treatment of disease must obviously be of paramount importance to every hospital. It is impossible as yet to conceive the whole of an urban community being served in this way with milk of a guaranteed purity, but some of the above recommendations might be acted upon by the purveyors and transporters of milk for the London market in the general interests of the population. We are publishing a short series of articles upon the railway transport of London milk, and in each article our correspondent points out the terrible risks of contamination that ensue upon the invariable habit of sending the milk cans by train unfastened and unsealed.

THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

THE Liverpool School of Tropical Medicine sent out its eighteenth expedition by the Union Castle mail steamer *Kenilworth Castle* on May 4th. The expedition, which consists of Dr. Allan Kinghorn and Mr. R. Eustace Montgomery, will be dispatched to Central Africa to study sleeping sickness. The two members of the expedition were entertained to dinner on May 2nd by Sir Alfred Jones, K.C.M.G. (the chairman of the School of Tropical Medicine). Dr. Kinghorn, in the course of an interesting speech, said that the Liverpool School of Tropical Medicine had taken a leading part in investigating the dread diseases of the tropics. With regard to sleeping sickness he was convinced that it might easily spread into Rhodesia and other parts of our southern territory. The object of the expedition was not only to fight sleeping sickness in British territory but to work out some scheme to prevent its spread. That meant that the destruction of the tsetse fly must be aimed at and they hoped that a new cure would be found in the near future. Mr. Montgomery also spoke, remarking that if sleeping sickness reached India it would be difficult to say what might happen. Dr. J. L. Todd (a member of former expeditions) hoped that the school would pursue its researches and remarked that it had already advised a method of treatment known as the "prophylaxis," which was a remedial measure and of which much was anticipated. The company included Viscount Mountmorres, Sir Edward Russell, the Vice-President of the Liverpool Chamber of Commerce, the chairman of the African Association, Dr. J. W. W. Stephens (Walter Myers lecturer in tropical medicine), Dr. T. R. Glynn, Professor Benjamin Moore, and others.

INTRAPLEURAL INJECTIONS OF FORMALIN IN RECURRENT PLEURAL EFFUSION.

THE repeated return of pleural effusion after aspiration is often a disappointment to the practitioner. In the *Boston Medical and Surgical Journal* of April 18th Dr. L. D. Chapin has reported the following case. A man, aged 29 years, came under observation on Oct. 5th, 1906. He stated that he was never robust and had suffered for five years from "asthma." About five weeks before he began to suffer from shortness of breath and fits of coughing. There were signs of bronchitis and of a left pleural cavity full of fluid. Paracentesis yielded three quarts of turbid serous fluid. The general condition was much improved and the dyspnœa was relieved for several days, but the fluid rapidly accumulated and a week after the paracentesis the same quantity of fluid was again removed. Nine days later the process was repeated. No tubercle bacilli could be found in the sputum or fluid removed and inoculation of guinea-pigs with the latter proved negative. The general condition was unsatisfactory. The attacks of coughing were frequent and exhausting, the appetite failed, and the patient seemed to lose ground daily. The temperature ranged from 99° F. in the morning to 102° in the evening. Three quarts of fluid were removed for the fourth time on Oct. 31st. On Nov. 6th a fifth paracentesis was necessary. Dr. J. B. Murphy of Chicago, to whom the case was mentioned, suggested the intrapleural injection of a 2 per cent. solution of formalin solution in glycerine. On Nov. 14th, after aspiration, one ounce of glycerine, containing ten drops of formalin, was injected through the needle. The fluid reaccumulated as before, but after a few days its height became stationary and then it began to decline. The patient's general condition and appearance improved rapidly and the temperature fell to normal. On Dec. 12th the effusion had all disappeared. Convalescence followed.

EPIDEMIC CEREBRO-SPINAL FEVER.

THE reported cases of epidemic cerebro-spinal fever show little change in the distribution of the disease throughout the country during the last seven or eight days. In London cases have occurred in Bermondsey and Islington, and the recovery of a lad admitted with this disease into the Whitechapel Poor-law infirmary eight weeks ago is announced. Other cases have occurred in Cumberland and Derby. In Scotland during the week ended May 4th there were 30 deaths from this cause registered in Glasgow, 7 in Edinburgh, 4 in Leith, 3 in Dundee, and 1 in Paisley. In Glasgow the weekly report issued on May 3rd showed that there were at that time 133 patients under treatment. Cases have also occurred at Dunfermline, at Cellardyke, at Forfar, and at Airdrie. In Belfast there has now been a total of 365 cases with 254 deaths, and there are at present about 40 patients under treatment. It is stated that the disease has made its appearance in the Victoria military barracks, Belfast.

THE Department of Public Health of Queensland in a bulletin dated March 31st states that for the five days ending Thursday, March 28th, no new cases of plague have been reported. The date of attack of the last case reported was March 17th. The date of the last bulletin was March 23rd. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on May 3rd states that for the week ending May 2nd no cases of plague had been reported. A telegram from the Acting Governor as regards Hong-Kong received at the Colonial Office on May 6th states that for the week ending May 5th there were 4 cases of plague and 4 deaths from the disease.

A SESSIONAL meeting of the Royal Sanitary Institute will be held at the Parkes Museum on Wednesday, May 29th, at 8 P.M., when a discussion will take place on Suggested Amendments of the L.C.C. By-Laws as to Drainage, to be opened by Dr. Louis C. Parkes, medical officer of health of Chelsea, Mr. J. Patten Barber, M.Inst.C.E., borough engineer, Islington, and Mr. Isaac Young, chief sanitary inspector, Battersea. General discussion is invited. The chair will be taken at 8 P.M. by Sir Shirley F. Murphy. Tickets for admission of visitors may be had on application to Mr. E. White Wallis, secretary to the institution.

THE summer session of lectures at the Hospital for Sick Children, Great Ormond-street, W.C., will commence on May 16th. The lectures are delivered on Thursday afternoons at 4 P.M., and the opening lecture will be delivered by Mr. G. E. Waugh on Hip Disease in Children. On May 23rd Mr. J. H. Parsons will lecture on Congenital Squint. The lectures are free to all qualified medical practitioners.

THE Harben Lectures of the Royal Institute of Public Health will be delivered on June 5th, 7th, and 11th, at 5 P.M., by Professor Paul Ehrlich, the subject being Experimental Researches on Specific Therapeutics. The lectures will be delivered in the theatre of the institute, 37, Russell-square, W.C.

Dr. Teizo Iwai, physician to His Imperial Highness Prince Sadanaru Fushimi of Japan, who is now on a visit to this country as the representative of the Emperor of Japan, has been appointed an Honorary Member of the Fourth Clas of the Royal Victorian Order.

THE Wightman lecture of the Society for the Study Disease in Children will be delivered on Friday, May 17th, 5 P.M., at 11, Chandos-street, Cavendish-square, W., Dr. Frederick Taylor; the subject will be Pneumonia Children.

Mr. J. Bland-Sutton, F.R.C.S. Eng., will deliver an addre on the Problem of Cancer at the Institute of Hygiene on Tuesday, May 14th, at 3.30 P.M.

Dr. A. J. Rice Oxley has been appointed physician-in ordinary to Her Royal Highness Princess Henry of Battenberg.

Brigade-Surgeon-Lieutenant-Colonel Charles E. Harrison, Grenadier Guards, has been appointed an Honorary Surgeon to the King.

MEDICINE AND THE LAW.

Quackery and Touting.

AT a recent inquest at Dewsbury it was proved that the deceased had been attended by a medical man during an attack of influenza but that subsequently he suffered from dropsy, and upon the advice of a man who worked under him at the mill where they were employed consulted a person named Hall. After death had occurred Hall was asked by the widow for a certificate of its cause, and the letter in which he replied bore the significant heading, "Dr. Hall's Hygiene Company, 16, Broad street, Pendleton." It contained an expression of the "company's" regret that the patient should have died and a suggestion that the medical practitioner who had previously attended him should be invited to certify. It also stated that the "company" was surprised at the widow's application as her late husband had known of their status and had been aware that they would be unable to give such a certificate as that asked for. The verdict of the jury in accordance with the medical evidence was to the effect that the deceased had "died from dropsy resulting from liver disease and aggravated by improper and ignorant treatment," and after their finding had been made known the coroner censured the widow for not obtaining medical advice for her husband when he became worse and was in a dying state. The case resembled many others in which foolish persons, not always of the least educated class, are deluded into applying to quacks, with the result that their lives are endangered or are sacrificed, but certain circumstances which the coroner sifted as far as he was able were serious enough to merit the attention which he very rightly gave to them. It was stated in the course of the inquest by the widow of the deceased that her late husband had been induced to consult "Dr. Hall's Hygiene Company" by a workman in the same mill and that the payments which he said he had made had consisted of £1 10*s*. to the former and £1 to the latter. The man in question, who was named Parker, was called and admitted that he had recommended Hall and had given the deceased the impression that Hall was a "proper doctor." He denied, however, that he received any commission from Hall. Parker's daughter then gave evidence to the effect that the £1 spoken of was for an appliance obtained from Hall for the deceased. She admitted, however, that she was Hall's agent for a certain district and that she received a commission upon what he obtained from patients introduced by her. She added that she accompanied the deceased to the quack who had then warned him of his danger and had advised him to consult a qualified practitioner. With regard to this, however, it must be added that medicine was produced which Hall had given to the deceased and which was stated to contain opium. The employment of agents paid by commission as described is a practice the dangers of which hardly require comment. The difficulty lies in preventing it in the existing condition of the law with regard to unqualified practice. It is to be hoped, however, that coroners when they have the opportunity will call attention to it and to its results as Mr. Maitland, the coroner for Dewsbury, has done.

An Incomplete Prescription.

An interesting case is reported from Brabant, Belgium, in the *Pharmaceutical Journal* of April 27th. A medical practitioner prescribed 50 grammes of glycerine of carbolic acid without any indication as to its strength. As the practitioner was attending a confinement the druggist to whom the prescription was handed supplied a preparation consisting of equal parts of glycerine and carbolic acid; thinking that the liquid was intended to be used to make carbolic solution by the direction of the practitioner. Unfortunately the liquid was intended for washing the newly-born infant and naturally the result was severe burning, which proved fatal. The court at Nivelles fined the medical man 300 francs for having prescribed a poisonous substance without indicating its strength. The druggist was, in the circumstances, also fined an equal amount. The case was taken to the Court of Appeal at Brussels, and the verdict of the lower court was upheld so far as the druggist was concerned, but the medical man's fine was increased to 600 francs.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Brighton County Borough.—The current annual report relative to this district contains an instructive account of an outbreak made up of cases of scarlet fever and of sore-throat which occurred in Brighton and apparently also in certain neighbouring districts in October, 1906. The cases of sore-throat, which were regarded as "scarlatinal," were considerably in excess of those of scarlet fever. The chief interest attaching to the outbreak was the fact that advantage was able to be taken of a method of keeping the milk registers which some of the dairymen had at the instance of Dr. Arthur Newsholme, the medical officer of health, adopted a year previously. All those familiar with the investigation of outbreaks thought to be milk-borne are but too painfully aware of the enormous difficulty of determining with accuracy the precise source of any given churn or churns of milk, and those who have had no such experience can ascertain the proportions of the problem by a reference to the historical outbreak with which the "Hendon disease" is associated. Fortunately for the partial elucidation of this Brighton outbreak the milk-vendor with whose milk it was associated had kept the records of his milk sources in such a fashion that he could trace at once to the farm the milk supplying any houses or group of houses and hence it became an easy matter to fix suspicion upon a certain farm and in a much more expeditious fashion than is provided for under the Infectious Diseases (Prevention) Act to stop the supply of milk. Had the records referred to not been thus available it would have been necessary to stop the whole of the milk supplied by this dairyman, but the information procurable enabled an arrangement to be arrived at by which in consideration of a sum of about £93 the milk from the suspected farm was withdrawn from consumption for a week. Such withdrawal fortunately coincided with a cessation of the outbreak and everyone, including the milkman, was satisfied. It may, however, be stated that fortunately the evidence associating the outbreak with the milk was very strong, so strong, indeed, that we fully agree that the expenditure involved was justified. The actual source of the infection of the milk could not be determined, but on the evidence suspicion must be held to attach to the cows themselves. One cow had a pustule on its udder, but in the view of the veterinary inspector it did not resemble those present in the Hendon disease. It is, however, regrettable that the pressure of work was so great that no cultures from this lesion could be made, more especially as other cows had apparently abscesses on their udders. A further account of the clinical features of the outbreak would, too, have been of value, as the whole story suggests that a mixed infection may have been in question, and we are interested to note that this point is referred to in a footnote. But the outbreak shows the importance of coöperation between local authorities and milk vendors, and it will be an advance if milk vendors in other places can be induced to keep their register in such a fashion as will enable the source of a suspected milk to be fixed upon at once. Dr. Newsholme furnishes in his report an interesting account of the voluntary notification of pulmonary tuberculosis in Brighton and of the manner in which better results are obtained under this system in Brighton than are secured in Sheffield under the compulsory system.

St. Anne's-on-the-Sea Urban District.—Dr. Frederick Booth, as an outcome of the recent report of the Royal Commission on Tuberculosis, advocates the periodic examination of the cattle in this district by a duly appointed veterinary surgeon and the acquirement of powers similar to those conferred by what are known as the "Liverpool Milk Clauses"—i.e., power to inspect the milch cattle and farms from which milk is imported into the district. There is no doubt that although those clauses can now be somewhat improved upon the powers which they confer are of considerable potential and actual value.

Surbiton Urban District.—The council of this district has shown itself alive to the importance of controlling the spread of tuberculosis from tuberculous cattle, and in 1900 it appointed a veterinary inspector to inspect at three monthly intervals every cow in the district which is kept for trade purposes. The council has also endeavoured to induce neighbouring sanitary authorities to take similar action in order that areas from which milk is introduced into Surbiton may be controlled adequately. Efforts have also been made to bring about coördination and coöperation as regards veterinary inspection in cows in adjoining districts. The last report of the Royal Commission should encourage Dr. M. Owen Coleman, the medical officer of health, to persist in his practices and efforts.

The Borough of Eccles.—Dr. W. M. Hamilton, the medical officer of health of this district, has been appointed by the corporation medical officer to the schools and in this capacity he has already carried out considerable inspectorial work amongst the scholars. Prior to his inspection the head teacher at the school is asked to have classified, according to standards, all children who are in any way defective and after examination of these children by the medical officer the parents are written to by the teachers, who have apparently entered enthusiastically into the work, advising that either a medical practitioner should be consulted or that the child should be taken to some suitable hospital. No actual treatment is undertaken by the examining officer, his duty being to ascertain the nature and extent of all defects. Enlarged tonsils, adenoids, and impaired sight and hearing have been the main defects noted, unless the presence of vermin can also be classed as a defect. Dr. Hamilton states that the fact of the examination has already led to more care and greater cleanliness.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8379 births and 4885 deaths were registered during the week ending May 4th. The annual rate of mortality, which had declined from 17·9 per 1000 to 16·0 in the four preceding weeks, further fell to 15·9 in the week under notice. During the first five weeks of the current quarter the death-rate in these towns averaged 16·7 per 1000, the rate during the same period in London being only 16·2. The lowest rates in the 76 towns last week were 6·4 in Hornsey, 6·8 in Bournemouth, 7·7 in Willesden, and 8·4 in East Ham and in Reading; the rates in the other towns ranged upwards to 24·6 in Middlesbrough, 25·0 in Oldham, 27·3 in Rochdale, and 30·5 in Tynemouth. The 4885 deaths in the 76 towns showed a further decline of 25 from the decreasing numbers in the four preceding weeks, and included 530 which were referred to the principal epidemic diseases, against numbers ranging between 563 and 505 in the four previous weeks; of these, 197 resulted from measles, 176 from whooping-cough, 59 from diphtheria, 46 from diarrhœa, 34 from scarlet fever, and 18 from "fever" (principally enteric), but not one from small-pox. No death from any of these epidemic diseases was registered last week in Halifax, Huddersfield, York, Ipswich, or in four other smaller towns; the annual death-rates from these diseases, however, ranged upwards in the other towns to 3·4 in St. Helens, 3·6 in Middlesbrough, 4·5 in Portsmouth, 5·1 in Salford, and 5·4 in Hanley. The fatal cases of measles in the 76 towns showed a decline from the high numbers in recent weeks; the highest annual rates therefrom were 2·6 in Birkenhead, Bolton, and Middlesbrough, 3·8 in Portsmouth, and 3·9 in Hanley. The deaths from whooping-cough, on the other hand, exceeded the number in any previous week of this year, and caused death-rates equal to 2·1 in Tottenham, 2·2 in Grimsby, 2·3 in Hornsey, and 3·7 in Salford. The deaths referred to diphtheria and diarrhœa also showed some increase, the death-rate from the former disease being equal to 1·2 in Walthamstow and in Rochdale, and to 1·3 in Leyton and in Reading. Scarlet fever caused three deaths in Bootle, equal to a rate of 2·3 per 1000. Two deaths were referred to "fever" in Cardiff. One case of small-pox was under treatment in the Metropolitan Asylums Hospitals at the end of last week; it is the first case of this disease admitted to these hospitals since the end of June last. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2628 and 2649 in the two previous weeks, had further increased to 2871 at the end of the week under notice; 346 new cases were admitted during the week, against 361 and 360 in the two previous weeks. The deaths referred to pneumonia and other diseases of the respiratory organs in London, which had steadily declined from 412 to 295 in the four previous weeks, further declined last week to 282, but exceeded by 24 the corrected average number in the corresponding week of the five years 1902–06. The causes of 50, or 1·0 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, West Ham, Newcastle-on-Tyne, Salford, and in 45 other of the 76 towns; the proportion of uncertified deaths, however, again showed considerable proportional excess in Liverpool, Sunderland, Gateshead, and Rochdale.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 20·0 and 20·6 per 1000 in the two preceding weeks, declined to 19·9 in the week ending May 4th, and exceeded by 4·0 the mean rate during the same week in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·5 and 12·0 in Perth and Aberdeen to 21·5 in Glasgow and 25·6 in Greenock. The 690 deaths in the eight towns showed a decline of 24 from the number in the previous week, and included 106 which were referred to the principal epidemic diseases, against 133 and 121 in the two preceding weeks. These 106 deaths were equal to an annual rate of 3·1 per 1000, which exceeded by 1·4 the rate from the principal epidemic diseases in the 76 English towns; they included 46 from "fever," 44 from whooping-cough, six from measles, six from diarrhœa, three from scarlet fever, and one from diphtheria, but not one from small-pox. The 44 deaths referred to "fever" exceeded the numbers in either of the two preceding weeks, and included 31 in Glasgow, seven in Edinburgh, four in Leith, three in Dundee, and one in Paisley; all these 46 deaths from "fever," excepting one of the 31 in Glasgow, were certified as fatal cases of cerebro-spinal meningitis. The 44 deaths from whooping-cough showed a decline of eight from the number in the previous week; they included 36 in Glasgow and three both in Edinburgh and Paisley. Of the six fatal cases of measles four occurred in Glasgow and two in Leith; and the six deaths attributed to diarrhœa included three in Glasgow and two in Greenock. Two deaths from scarlet fever were recorded in Edinburgh. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 103 and 109 in the two preceding weeks, further rose to 127 in the week under notice, but were ten below the number in the corresponding week of last year. The causes of 22, or 3·2 per cent., of the deaths registered in the eight towns during the week were not certified or not stated; in the 76 English towns the proportion of uncertified deaths in the week under notice did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 27·1 and 33·5 per 1000 in the two preceding weeks, declined to 26·4 in the week ending May 4th. During the first five weeks of the current quarter the death-rate in the city averaged 28·4 per 1000; the rates during the same period did not exceed 16·2 in London and 18·3 in Edinburgh. The 198 deaths of Dublin residents during the week under notice showed a decline of 53 from the high number in the previous week, and included 14 which were referred to the principal epidemic diseases, against 18 and 29 in the two preceding weeks; of these, ten resulted from whooping-cough, three from measles, and one from diarrhœa, but not one either from small-pox, scarlet fever, diphtheria, or "fever." These 14 deaths were equal to an annual rate of 1·9 per 1000, the rate during the same week from the principal epidemic diseases being 1·6 in London and 1·8 in Edinburgh. The fatal cases of whooping-cough and measles showed a decline of five and seven respectively from the high numbers returned in the previous week. The 198 deaths from all causes included 36 of children under one year of age and 45 of persons aged upwards of 60 years; each of these numbers showed a marked decline. 11 inquest cases and five deaths from violence were registered; and 87, or 43·9 per cent., of the deaths occurred in public institutions. The causes of four, or 2·0 per cent., of the deaths in Dublin were not certified; the percentage of uncertified deaths during the week did not exceed 1·0 in London, while it was 4·3 in Edinburgh. The 169 deaths registered in Belfast during the week under notice included 25 which were referred to cerebro-spinal fever or cerebro-spinal meningitis, showing a decline of two from the number in each of the two preceding weeks.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: A. L. Christie to the *Sappho*; G. G. Borrett to the *Royal Arthur*; and A. M. Page to the *Nile*. Staff-Surgeons: A. H. Jeremy to the *Carnarvon*, on recommissioning; H. B. Hall to the *St. George*; and J. W. Craig to the *Royal Arthur*. Surgeons: W. E. Ormsby to the *Tamar*; and B. R. Bickford to the *Excellent*, for the *Grafton*. Civil Practitioner: M. O'Brien to be Surgeon and Agent at the Isles of Arran, Galway. Staff Surgeon Arthur Reginald Bankart, M.V.O., K.H.P., has been promoted to the rank of Fleet Surgeon in His Majesty's Fleet (dated May 5th, 1907).

GRENADIER GUARDS.

Brigade-Surgeon-Lieutenant-Colonel Charles E. Harrison, Grenadier Guards, to be an Honorary Surgeon to the King, and to be a Brevet Colonel, *vice* Surgeon-General Sir H. J. K. Innes, K.C.B., deceased (dated March 13th, 1907).

ARMY MEDICAL SERVICE.

Lieutenant-Colonel Arthur P. O'Connor, C.B., from the Royal Army Medical Corps, to be Colonel (dated April 5th, 1907).

ROYAL ARMY MEDICAL CORPS.

The undermentioned Captains to be Majors (dated April 29th, 1907):—Septimus H. Fairrie, George T. K. Maurice, Francis E. Gunter, and John H. Campbell, D.S.O. The seconding for service with the Egyptian Army of Lieutenant Marcus G. Dill bears date Feb. 14th, 1907.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions among officers of the Indian Medical Service:—Captains to be Majors (dated Jan. 29th, 1907): Charles John Robertson-Milne, Algernon Francis Stevens, Clement Henry Bensley, Francis Hammond Watling, Samuel Evans, Edgar John Morgan, James Haldane McDonald, Frank Wall, Charles Montague Mathew, John Stephenson, Frank Needham Windsor, Walter Barrie Turnbull, Ernest Edwin Waters, Edmund Moritz Illington, and Charles George Webster.

The King has also approved of the retirement of the undermentioned officers:—Surgeon-General Adam Scott Reid, C.B. (dated March 25th, 1907), and Lieutenant-Colonel Montague Stokes Eyre (dated April 7th, 1907).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major George Hollies, to be Surgeon-Lieutenant-Colonel (dated April 16th, 1907).

VOLUNTEER CORPS.

Royal Engineers (Volunteers).—3rd Lancashire: Samuel English to be Surgeon-Lieutenant (dated March 30th, 1907).

Rifle.—4th Volunteer Battalion, The Royal Fusiliers (City of London Regiment): Surgeon-Lieutenant J. K. Brownlees resigns *his commission (dated March 25th, 1907). 1st Dum*bartonshire Volunteer Rifle Corps: Surgeon-Lieutenant A. G. Hay, to be Surgeon-Captain (dated March 1st, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Eastern Command: Woolwich Companies: Captain T. W. Bartlett resigns his commission (dated March 31st, 1907).

MR. HALDANE'S ARMY SCHEME.

The motion of the Prime Minister for confining discussion on the Territorial Army Bill to a limited period recently occupied the attention of the House of Commons and was carried. On a previous occasion in the House of Lords the Earl of Wemyss put a question to the Under Secretary for War having a very important bearing upon the new Army scheme—namely, as to the minimum age of soldiers for foreign service. About this we are probably destined to hear more, for notwithstanding the results of previous experience the temptation is always in the event of any pressure to embark soldiers for service in India whilst they are still too young and immature for the work and climate. This is a matter which calls for serious consideration if we are to avoid the *occurrence* of much unnecessary sickness and inefficiency in that country. Mr. Haldane has, as everyone knows, addressed himself to the question of army reform with great constructive skill and boldness and his scheme, about the success of which much difference of opinion prevails, nevertheless holds the field and is, we imagine, bound to be adopted and tried.

TINNED MEAT RATIONS.

The War Office has sent out the following circular to all the commands in the home stations in giving instructions for the weekly issue of one pound of preserved meat to the army in lieu of fresh-killed meat:—

> The establishments in which the brands of American tinned meat now being issued to the troops are manufactured have been carefully inspected by officers sent specially to America for the purpose, and their reports have satisfied the Army Council that the quality of the tinned meat used, and the conditions under which it is prepared and canned by the firms now supplying the army, are in every way satisfactory.

THE UNITED SERVICE MEDICAL SOCIETY.

A meeting of medical officers in the Navy, Army, Indian Service, and Auxiliary Forces was held at the Royal United Service Institution, Whitehall, S.W., on May 2nd, when a society to be known as the United Service Medical Society was formed for the furtherance of the sciences bearing on the preservation of health among the forces afloat and ashore, at home and abroad, in war and in peace. Inspector-General H. M. Ellis, Director-General of the Medical Department of the Royal Navy, who presided, said that the present was a peculiarly fitting time for the formation of such a society, as the Royal Army Medical Corps had now got a home in London and it was from the Army Medical Department that the inception of the movement had come. Inspector-General Ellis was elected to be president of the society for one year, Fleet Surgeon W. W. Pryn, R.N., and Lieutenant-Colonel C. H. Melville, R.A.M.C., were appointed honorary secretaries, and Lieutenant-Colonel D. Wardrop, R.A.M.C., was appointed honorary treasurer. The affairs of the society will be managed by a council consisting of the president and eight officers elected by the society, representing the different services.

THE ROYAL ARMY TEMPERANCE ASSOCIATION.

A conference in connexion with the Royal Army Temperance Association was held on the morning of May 3rd, at Caxton Hall, Westminster, at which General Lord Methuen presided. The annual meeting was held in the afternoon, under the presidency of Mr. Haldane. Mr. Haldane, before presenting the awards gained by those units in the various branches of the army which contained the highest percentage of abstainers, gave an address in which he remarked that perhaps one reason why the army had not always been as popular as was desirable was that the people had not felt that the personal lives of the men reached the desired level. Recent years had, however, seen a change for the better. The army was better looked after and better paid; the terms of service were better suited to the habits and needs of the people and the men had better chances of employment afterwards. But the difficulty of getting recruits meant that something was wrong. The tradition which kept men back dated from the period when they were secured almost, or even quite, by compulsion, when no one looked after them at all, and when everyone, without exception of rank, drank to excess. Officers, non-commissioned officers, and men realised now the enormous waste of physical, intellectual, and moral force to which drinking led. The key to a larger supply of recruits lay in an improved social condition of the army. Therefore, the work of the social reformer and the minister of religion was just as real as that of the army surgeon and those who prepared the men for fighting. He was glad that the association had decided not to exclude the really moderate drinker.

"Audi alteram partem."

DOURINE IN CANADA.

To the Editors of THE LANCET.

SIRS,—Pathologists will be interested in the information that the trypanosoma equiperdum has been found in a mare clinically affected with dourine, or *maladie du coït*, at the quarantine station established by the Department of Agriculture at Lethbridge, Alberta, in 1904. The first demonstration was made by Dr. E. A. Watson and Dr. M. V. Gallivan on Feb. 11th, 1907, in material taken from a vesicle on the mucous membrane of the vagina of the animal above referred to, which was found to be affected with dourine on the premises of her owner near Lethbridge, on Dec. 21st, 1906, and was subsequently removed to the quarantine station for purposes of experimental observation. The disease was successfully transmitted in February to a yearling filly and the parasite subsequently observed in preparations from a fresh plaque. The finding was confirmed by Dr. C. H. Higgins, pathologist of the department, on March 21st, and was further observed in preparations taken by him on the 23rd and 25th of the same month.

The identity of dourine, or *maladie du coït*, as seen on this continent and hitherto diagnosed by American and Canadian veterinarians from clinical manifestations alone, with the disease as known in Africa and Asia, as well as in Southern Europe, is thus fully established. A detailed report of the discovery and of the work which led up to it, as well as of the steps subsequently taken, will be issued at the earliest possible date.

I have the honour to be, Sirs, your obedient servant,

J. G. RUTHERFORD,
Veterinary Director General.

Ottawa, April 19th, 1907.

LARGE VESICAL CALCULI.

To the Editors of THE LANCET.

SIRS,—On Feb. 16th, 1907, you kindly published in THE LANCET a short note on a case of large vesical calculus which I had removed. I there stated that it was the largest calculus successfully removed of which I had seen a record. I quoted from "Anomalies and Curiosities of Medicine," Gould and Pyle, published in 1900. I thought the writers would have exhaustively looked up the subject and that if they had not found a record of a larger stone I might safely conclude that no such record existed. Since then I have found out there are larger stones which have been successfully removed and shall be much obliged if you will allow me to make the necessary corrections.

Dr. F. M. Sandwith's letter in THE LANCET of Feb. 23rd recalls Mr. H. M. N. Milton's case reported in THE LANCET of Sept. 16th, 1893, of a stone weighing 34½ ounces removed from an Egyptian fellah by the suprapubic operation in which the peritoneum was opened in order to extract the stone. The patient died two months after the operation. The stone is now in the museum of the Royal College of Surgeons of England. I have also received a letter from Dr. F. C. Madden of Cairo referring to this case and telling me of another successfully removed by Mr. Milton by crushing weighing 20 ounces. Sir *Thomas* Smith kindly wrote to me calling my attention to the case he had successfully operated on, the stone weighing 24½ ounces and recorded in THE LANCET of August 7th, 1886. He also referred to some other large stones unsuccessfully removed

Dr. W. B. Hunter's case, a stone removed from an Indian native weighing 25 ounces; death ensued on the fourth day.[1] Mr. Walter Rivington's case; the stone was said to be larger but weighed less than Sir Thomas Smith's.[2] Mr. J. Rutherford Morison's case; the stone weighed 20½ ounces; death occurred on the fourteenth day. I also received a letter from Sir Constantine Holman telling me of large stones removed at Canterbury and Chichester. I have to thank Mr. T. Whitehead Reid of Canterbury and Dr. D. Ewart of Chichester for giving me information about these stones. The Canterbury stone weighed 10 ounces and the Chichester one 7 ounces 35 grains. Mr. R. Lawford Knaggs told me of Mr. N. C. Davies-Colley's case, for particulars of which I am indebted to Mr. A. Ralph Thompson. The stone was successfully removed by the suprapubic operation on Oct. 30th, 1896, and weighed 16 ounces. In Ashurst's "International Encyclopædia of Surgery" a case is referred to removed by Dunlop of Springfield, Ohio, from a patient, aged 66 years. The stone weighed 20 ounces and the patient lived three years after the operation.

Below is a list of successful cases which I have endeavoured to make as complete as possible:—

1. Milton: 34¼ ounces; death two months after operation.
2. Sir Thomas Smith: 24½ ounces; complete recovery.
3. Dunlop: 20 ounces; patient lived three years.
4. Milton: 20 ounces; removed by lithotrity.
5. Littlewood: 18½ ounces; patient lived ten months.
6. Hatch: 17 ounces.
7. Davies Colley: 16 ounces.
8. Harmen (Norwich): 16 ounces.
9. Mayo (Winchester). 14 ounces 2 drachms.
10. C. R. Pike (St. Vincent): 13½ ounces.
11. Clinè: 13 ounces.
12. Cheselden: 12 ounces.
13. Paré (1570): 9 ounces.

I think I may safely state that Mr. Milton of Cairo has successfully removed the largest recorded stone, the patient living two months; Sir Thomas Smith has removed the largest stone in which the patient completely recovered from the operation; and that the case I have recorded is the second largest stone successfully removed in Great Britain.

I am, Sirs, yours faithfully,
Leeds, May 4th, 1907. H. LITTLEWOOD.

FEES FOR EXPERT EVIDENCE.

To the Editors of THE LANCET.

SIRS,—May I invite the attention of the profession through your columns to the subject of witnesses' fees for expert evidence? Some months back I was *invited* by a solicitor to give "proof" of evidence as to sanity of testator in a will case. I did so but stipulated *in writing* the amount of my fees for such attendance in London to give evidence. This I thought was a sufficient safeguard. I was afterwards subpœnaed and at great cost and trouble to myself had to go up to London twice and give evidence. The case was lost but the costs came out of the estate. The sum tendered me for my attendance leaves me actually out of pocket, as I received the merely *taxed* costs of the action. I have since learned that the plaintiff (of whom I knew nothing, having been engaged entirely by the solicitor) had no means whatever for entering on such an action. I am informed that I have no legal remedy, as I had no undertaking from the solicitor as to my costs. I suppose, therefore, that if the costs had not come out of the estate I should have got *nothing*. I may mention that all the other witnesses on the same side have suffered similarly. I would wish therefore to emphasise to my medical brethren the absolute necessity of obtaining a written guarantee from the solicitor engaging them as to the payment of their costs. I have often given evidence in medico-legal cases but shall never do so again without a due guarantee beforehand.

I am, Sirs, yours faithfully,
C. E. RICHMOND, B.Sc. Vict., F.R.C.S. Eng., &c.
May 6th, 1907.

⁂ Our correspondent rather confounds two things. The fee for *an examination and report* stands on exactly the same footing as any other medical service and the party on whose account the order may have been given is responsible for the payment. If there is any doubt as to the ability of the party to pay it is wise to ask for payment before the examination is made. As to the *charge for attendance in court* and proper travelling expenses payment for these can be claimed by any witness *before* he is sworn and the judge then directs the payment, but if a witness is sworn before making the claim he will have then to rely on the ability of the plaintiff or defendant, as the case may be, to make the payment. The judge has nothing whatever to do with the fee for the examination or in other words the qualifying fee.—ED. L.

PHARYNGO-KERATOSIS TREATED BY APPLICATIONS OF SALICYLIC ACID IN SULPHO-RICINATE OF SODA.

To the Editors of THE LANCET.

SIRS,—So many doubtful but alleged remedies eventually become stereotyped into the students' text books to the chagrin of the practitioner and the patient alike that it would, perhaps, be as well at once to point out that Dr. Dundas Grant's "rigid experimental test" from a scientific standpoint —and I am only concerned with the scientific aspect of the matter—is really of little value. Dr. Grant addresses a letter to your issue of May 4th on the ground of supplying an omission; in that letter he himself makes a very material omission, for he makes no mention of the vigorous local treatment carried out for a month or six weeks immediately before the application of this "rigid experimental test." According to the official report (of which I inclose a copy), when the patient was first seen in March, 1906,

> Various isolated applications were made; in the first instance a saturated solution of salicylic acid in alcohol to the spots on the right tonsil, the galvano-cautery to those on the left one, then pure formalin to the left one, and a 10 per cent. solution of sulpho ricinate of soda to the right. In April she was given a 1 per cent solution of formalin in glycerine and distilled water, which she applied daily for a month, at the end of which time comparatively no change had taken place. In April, 1906, she commenced the daily application of a 10 per cent. solution of salicylic acid in sulpho-ricinate of soda.

With the result so vitiated by previous treatment it seems idle to dignify any subsequent application as a "rigid experimental test" which "showed incontrovertibly that the improvement was due to the application." The one rigid and incontrovertible fact in the case is that the patient was under this treatment for 12 months and at the end of that time was not cured.

I am, Sirs, yours faithfully,
May 7th, 1907. W. JOBSON HORNE.

THE UNIVERSITY OF LONDON AND MEDICAL EDUCATION.

To the Editors of THE LANCET.

SIRS,—It was with considerable regret that I read your leading article on the above subject[1] because, in my opinion, you convey to your many readers scattered throughout the country an erroneous impression of the present constitution of the University and of the aims of a majority of the teachers which constitute its medical faculty. You have written: "There is an indication of a temporary ascendancy of reaction against the movement for the conversion of the old examining board into a real teaching University." The indication, I take it, is the recent election of Dr. J. Calvert and Dr. L. Hill to the Senate of the University. If that is so, then you are wrong in your inference that those who voted for them are "against the conversion of the old examining board into a real university." With the affiliation of the present medical schools in the University six years ago the days of the University as a medical examining board ended and those who voted for Dr. Calvert and Dr. Hill certainly do not wish to see those days back again. What they did vote against, and in my opinion rightly, was the introduction into London of a university of the type of the great German or Scotch universities. The present medical schools constitute the basis for an ideal medical faculty, which could be made better than any the world has ever seen. They are planted where they ought to be—under the walls of great hospitals; their teachers have liberty to work out the best that is in them; the students have individual attention. London is not a city in any sense of the word; and the university that serves Berlin or Edinburgh could not answer for London, which is an urban kingdom and ought to support at least 11 medical schools, the number to be found in Scotland. Those who voted for Dr. Calvert and Dr. Hill have in their minds the development of such a university as, I have so briefly outlined and wish to see these colleges of the University assisted and not crippled. The London medical schools deserve assistance; look at the research work and the teaching that is done in them. In every department of medicine they contribute more than a fair share to the progress of knowledge. With the best will in the world they are ready to compete with other universities and colleges which are supported by bounties in the shape of endowments. They are poor, contending, jealous, and ambitious, all points in their favour. They can command the best of the younger men who wish to become leaders in medicine. These are the aims of the "party of reaction"—aims which in their nature are certainly not reactionary.

[1] THE LANCET, Jan. 16th, 1888.
[2] THE LANCET, August 14th, 1886 (unsuccessful).

[1] THE LANCET, May 4th, p. 1235.

I am, Sirs, yours faithfully,

ARTHUR KEITH.

London Hospital Medical College, E., May 6th, 1907.

To the Editors of THE LANCET.

SIRS,—In your leading article in THE LANCET of May 4th on the University of London you hardly do justice to the body of graduates who are opposing the present policy of the Senate. For some years past the medical schools of London have experienced a decline in their annual entries. The undoubted cause of this decline has been the attractive influence of provincial universities. Although in actual practice every medical man is "doctor," yet the ordinary honest man feels compunction when using a title to which he has no claim. It is here that the many small universities exercise their greatest force in diverting the stream of students from London. But London stands pre-eminent in the enormous mass of clinical material, after all the greatest factor in our training, which it offers. It also possesses a University with a high standard for pass degrees. What it lacks, however, is an organised method of teaching. The slipshod methods of 50 years ago are inadequate to the requirements of the twentieth century. Whether reform will be best obtained by concentration is a matter for the teaching bodies who alone are best capable of judging. At the same time one must not lose sight of the fact that large sums of money are sunk in buildings expressly adapted to the requirements of elementary medical education. The fear that loss of capital will follow concentration must have weight in the minds of those affected.

Now we, the ordinary practising graduates of the University, find, or think we find, ourselves threatened by another danger. We say that the various alterations in the examinations of the University all tend to the more easy attainment of its degrees. We say that London can attain the position that it deserves by making its teaching adequate to its degrees, not by making its degrees fit its teaching. In my own case my father deliberately chose that his son should enter the University of London in preference to either of the old universities in the belief that the London degrees marked the high water mark of medical attainments.

The members of the Graduates' Association share the same belief, and it is in the enjoyment of this belief that they are pursuing the course that you, Sirs, term reactionary. The liberal progressive policy of the Senate to us appears only as a breach of faith.—I am, Sirs, yours faithfully,

Manchester, May 4th, 1907. M.D. LOND.

A NEW HOSPITAL FOR INFANTS.—On May 2nd the Duchess of Albany laid the foundation-stone of a new hospital for infants at Vincent-square, Westminster, S.W. As explained to the company present by Lord Cheylesmore, chairman of the hospital committee, the hospital was founded four years ago by Mrs. Robert Mond in Denning-road, Hampstead, where accommodation was provided for 20 infants. This lady had not survived to see the remarkable success which had attended the work of this hospital in which during four years only more than 500 infants had been treated. Her husband, Mr. Robert Mond, however, had offered to erect the new hospital as a memorial to his wife at a cost of £30,000. Mr. J. S. Fletcher, M.P., in proposing a vote of thanks to the Duchess of Albany for her interest in the institution, dwelt upon the great prospects of future utility before the new hospital.

SOME TURKISH LAZARETS

AND OTHER SANITARY INSTITUTIONS IN THE NEAR EAST.

BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.

(*With Reproductions of Photographs taken by the Author.*)

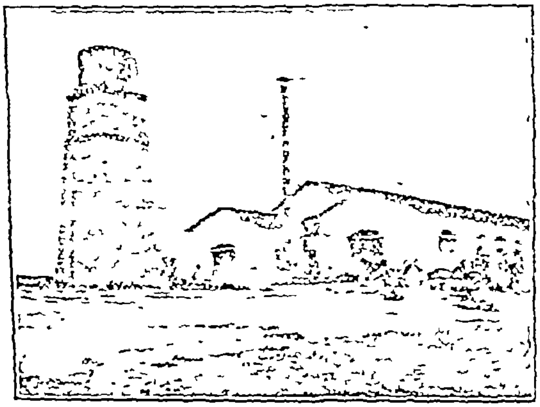
III.[1]

THE CAMARAN LAZARET (*continued*).

The Three Disinfecting Pavilions.—Modifications Proposed.—The "Douche Baths."—Moveable Disinfecting Stove.—The Mode of Housing the Pilgrims.—The Two Types of "Arish," Old and New.—Their Advantages and Disadvantages.—Stone Houses Recommended.—The "Specimen-house."—The "Houses of Distinction."—Tents.

THERE are three large disinfecting pavilions at Camaran. All are situated near the sea and, roughly speaking, the first is between the first and second camps or cordons, the second between the third and fourth, and the third between the fifth and sixth. Under the plan proposed by the Commission the third pavilion will be transferred to a spot near the land end of the third landing stage, where it will serve for pilgrims going to the fifth and sixth cordons (in their new position). All three blocks are built on the same plan, but it is only at the first that the annexe for douche-baths has been built. The materials, however, exist for the construction of a similar annexe at each of the other two. They are large buildings, as may be seen in Fig. 5; they are solidly built of the madreporic stone of the neighbourhood, covered (for the most part) with lime plaster. A large verandah, in matting, has been run up along one side of the first pavilion; but the material for a "pucca" verandah to all three has been bought and is in stock at the lazaret only waiting to be put up.

FIG. 5.



Third disinfecting pavilion and water tower.

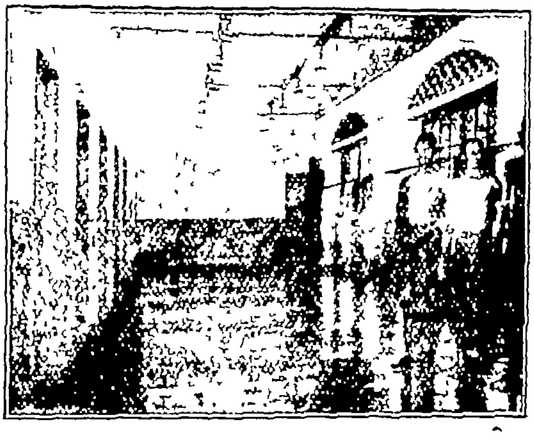
The internal arrangement of the first pavilion is shown in Plan I. The Commission's report contains two plans, one of the pavilion as it is and one as it will be when its proposals are carried out; it is the second of these that is reproduced on a small scale here. The pilgrims and baggage enter a large hall, some 20 metres long and seven metres wide, the floor of which is of brick and the roof of galvanised iron. This room has hitherto served for the sorting of the baggage, for the chemical disinfection of such objects as require it, for the undressing of the male pilgrims, and for their medical examination. As the Commission points out, it is impossible that each of these four operations can be properly carried out in one and the same room. There are, as a matter of fact, under the present arrangement, much disorder and confusion, the room being soon filled with chattering pilgrims and baggage of every kind; the sorting of the latter is not very perfectly done, chemical disinfection is most indifferently performed, and a proper medical examination is almost impossible. It has been decided, therefore, to partition off the south end of the hall, which will be reserved for chemical disinfection; three large cement troughs will be constructed there, in which different chemical solutions can be prepared on a large scale. At the other end of the hall a space some 5 by 5½ metres will be partitioned off to make the men's undressing-room, and where the corridor leaves this to lead to the baths a small inclosure will be made for the medical visit. In this way every pilgrim must pass singly by the medical man before he can leave the undressing-room, and being already undressed the medical examination can be made both much more rapidly and much more thoroughly. The remainder of the large entrance hall will be used for the sorting of the baggage. That which can pass through the disinfecting stoves will be taken to them and the rest will pass to the room for chemical disinfection.

---

[1] Nos. I. and II. were published in THE LANCET of April 27th (p. 1155) and May 4th (p. 1251), 1907, respectively.

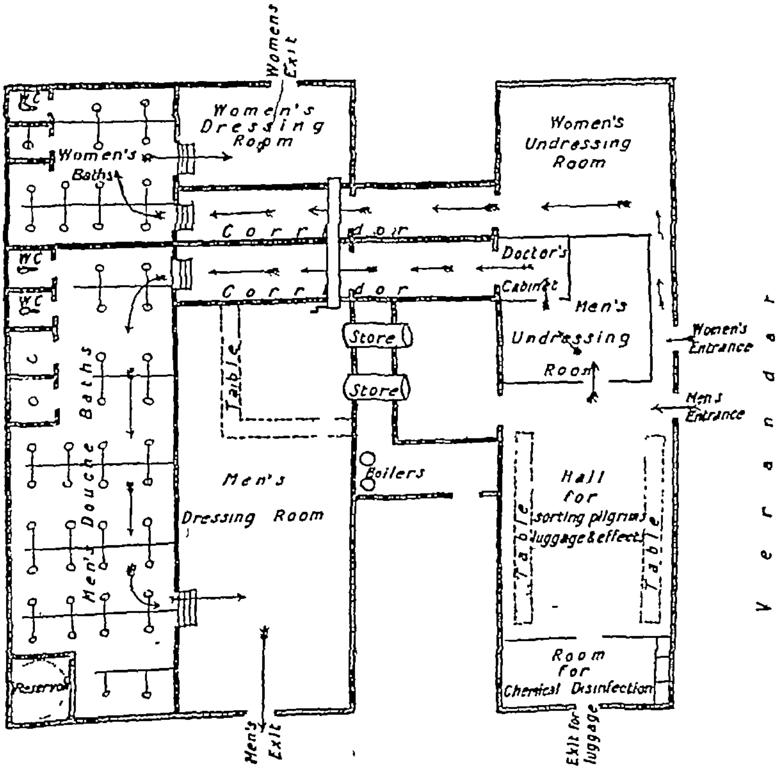
There are two disinfecting stoves in each pavilion, or six in all. Of the six three are from the firm of Geneste, Herscher, and Co. and three from that of Dehaitre. In each block there are two boilers, each of which can be used indifferently for either of the two stoves. The stoves pass through a partition wall which entirely cuts off the "infected" from the "clean" half of the building. The pilgrims' clothes and other objects not injured by steam are placed in the stoves at the "infected" end and removed at the "clean" end by other employees. The "clean" end is in the men's dressing-room. The women's clothes are transferred from this room across the two corridors to the women's dressing-room by means of a circular belt worked by a handle.

FIG. 6.



Men's douche baths in the first disinfectin station.

PLAN .



Ground plan of a disinfecting pavilion at the Camaran lazaret, with modifications proposed by the Commission. Scale 1 to 350.

The course followed by the men and women respectively is shown in Plan I. by means of arrows. It will suffice here to follow the men; having undressed, they receive a cloth, like that used in Turkish baths, and, having undergone the medical examination, they pass along a corridor to the "salle des bains-douches." This is a long hall with floors and walls of cement and the "roses" for the douches of warm sea-water in the ceiling (Fig. 6). Along one side of the hall is a series of cubicles, four of which are latrines (to be reduced to two), and the six others contain single douches for the better class pilgrims. Attendants arrange the pilgrims in rows under the douches; a signal is given and the water is turned on for a short time. The pilgrims are then well soaped all over and scrub themselves thoroughly or are scrubbed by the attendants; at another signal the water is turned on again to remove the soap and the pilgrims then pass into the dressing-room. This is another large hall 17½ metres long by 7 wide. Here they receive their disinfected clothes, dress, and pass out into the open by the door of exit.

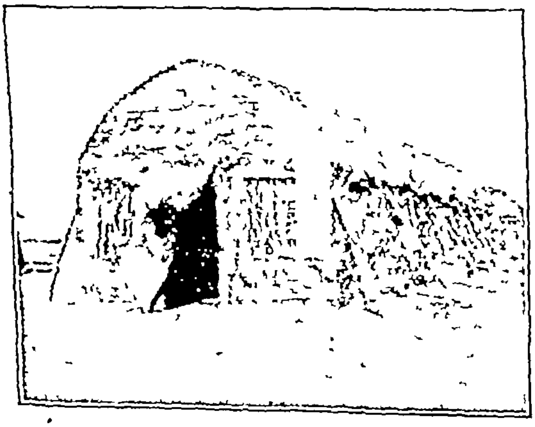
For these arrangements as a whole I have nothing but praise. Several modifications of detail are proposed by the Commission, but with the exception of those mentioned above—the division of the large entrance hall into separate rooms for the four separate operations now imperfectly conducted in the single hall—these modifications do not touch any point of capital importance The completed disinfecting blocks at Camaran compare, indeed, favourably with those in any other lazaret I know.

Mention must here be made of a moveable disinfecting stove on wheels possessed by the lazaret. It was bought in 1898 from Geneste, Herscher, and Co. At present it stands unutilised in a shed. The Commission proposes to place it definitely in a small disinfecting pavilion to be built between the hospitals for ordinary and infectious diseases, which will be dealt with in a later article.

The pilgrims, having completed their bath and disinfection, enter the camps, or "cordons," in which they pass the rest of their quarantine. There are six of these cordons; their position and relative sizes are seen in Plan II.,[1] which shows the lazaret in its present condition. The second plan shows it as it will be after the proposals of the Commission have been carried out. It will be easier to understand what these proposals are and the reasons for them by describing first the kind of house occupied by the pilgrims; secondly, the cordon, which is made up of a group of such houses; and, thirdly, the arrangement of the cordons and their relation to other portions of the lazaret.

At present the bulk of the pilgrims are lodged in large houses or huts with matting walls and palm-thatched roofs. Such a house is known as an "*arish.*" There has been considerable controversy as to the suitability of these houses for lodging pilgrims. There are two types of arish, the "old type" and the "new type." Both are built of a skeleton of wooden beams, rods, and canes, on which are nailed, inside and outside, squares of native matting (made of palm leaves), and, as stated, the roof is thatched with a thick layer of palm leaves. The new type differs from the old in having a thatched verandah on either side and in some other minor details; it is also better constructed than the old model. The Commission went very carefully into the question of cost and found that though a new model arish costs about £T.30 and an old model only about £T.15, the difference is compensated by the greater comfort which the former offers to the pilgrims, by its more presentable appearance, and by the fact that it lasts nearly twice as long. The external appearance of each of the two models is shown in Figs. 7 and 8.

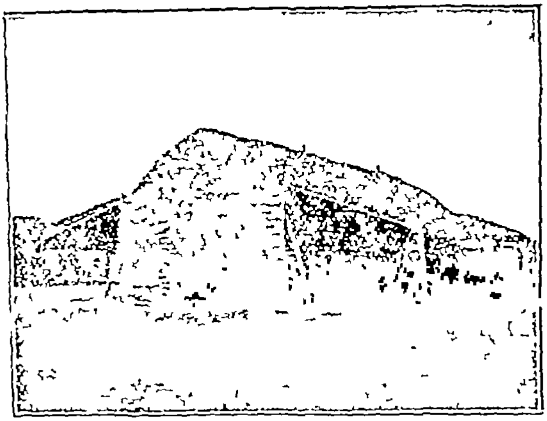
FIG. 7.



An "arish," old model.

The floor of these houses is simply the desert sand of the island. Their length is 19 or 20 metres, their width about 5 30 metres, and their height in the middle from 4½ to 5 metres. In a tropical climate, such as that of Camaran, a house of this kind offers several advantages: it is cheap; it can be easily burnt and rebuilt at little cost in case of an epidemic; it offers sufficient protection against the sun; and it is thoroughly ventilated, the entire walls being of porous matting. On the other hand, it is difficult to disinfect; the walls harbour dust and dirt; spiders and rats infest the space between the inner and outer layers of matting; and when rain falls it is difficult to prevent the interior from becoming damp. In the case of two of the six cordons (the first and third) which lie almost at sea-level the houses are actually inundated after heavy rains. Rain is not very common at Camaran, but three or four times each winter there is likely to be a fall of some duration and severity, and on these occasions the pilgrims in the first and third camps are liable to suffer much discomfort. The "new model" arish offers much better protection against rain than the old, because of the verandah on either side and of its better construction. The Commission therefore recommends that in future all arishes shall be built of the new type. It also makes other special recommendations for the first and third camps in order to protect the houses there from inundation during rain.

FIG. 8.

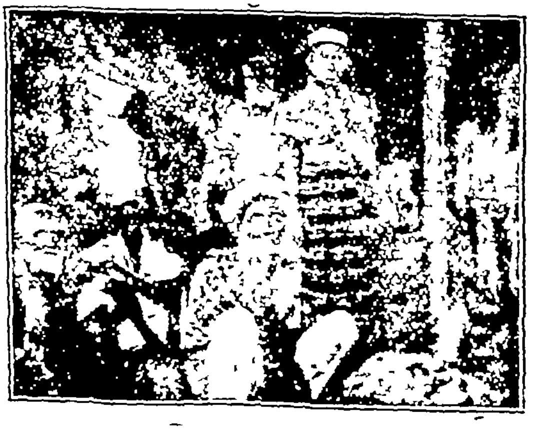


An "arish," new mode

There can be no doubt that stone houses, such as exist at Abu-Saad or at the Egyptian lazaret of Tor, are greatly preferable to these mat houses, but the expense of their construction is very great. It is reckoned that to furnish all the pilgrims at Camaran with stone houses would involve a total outlay of some £T.50,000 or £T.60,000. The Commission nevertheless recommends to the Turkish Government the desirability of building such houses and spreading the expense over a series of years; but it must be confessed that there is little likelihood of this recommendation being carried out.

In Fig. 9 the interior of a mat house is seen with pilgrims already lodged in it. On entering such a house the first impression is one of disorder and chaos, but it is soon seen that there is a certain order in the disorder; the pilgrims hang cloths or carpets to make small enclosures, in which are placed the women and children. They spread rugs or matting on the floor and are soon quite as comfortable as in their own homes. It had been suggested to have a sort of

FIG 9



Pilgrims in arish.

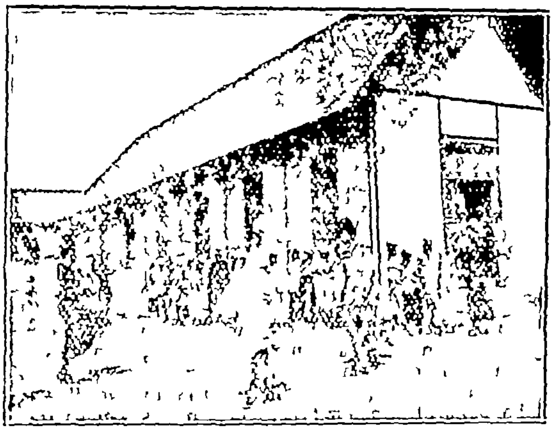
---

[1] Plan II. will appear with the next article

moveable flooring running along each side of the arish forming a kind of continuous camp-bed raised some two feet or so from the floor, but the Commission does not recommend this. It would only cause worse disorder than at present, it would diminish the air-space, and lead to accumulation of filth under the boards. To furnish all the houses at Camaran with such floorings would cost about £T 5000, and the Commission prefers to spend such a sum on more useful undertakings.

When the complete repair and "refection" of the Camaran lazaret were put in hand ten years ago the possibility of building "*pucca*" houses for the pilgrims instead of mat arishes was taken into consideration and a "specimen house" was run up in the *fourth cordon.* The exterior of this house is seen in Fig. 10. It has practically the same dimensions as an arish; the walls are of brick on an iron frame, the roof of Marseilles tiles resting on wooden beams and iron rods; the floor is of cement tiles. It must be confessed that this house is not the most appropriate in the special circumstances. The absence of verandahs on either side and of a ceiling in the interior makes the house extremely hot. A simple tile roof without a ceiling below is little suited for a tropical climate, the sun beats down on the tiles, which become intensely hot, and these radiate their heat to the interior.

FIG 10.



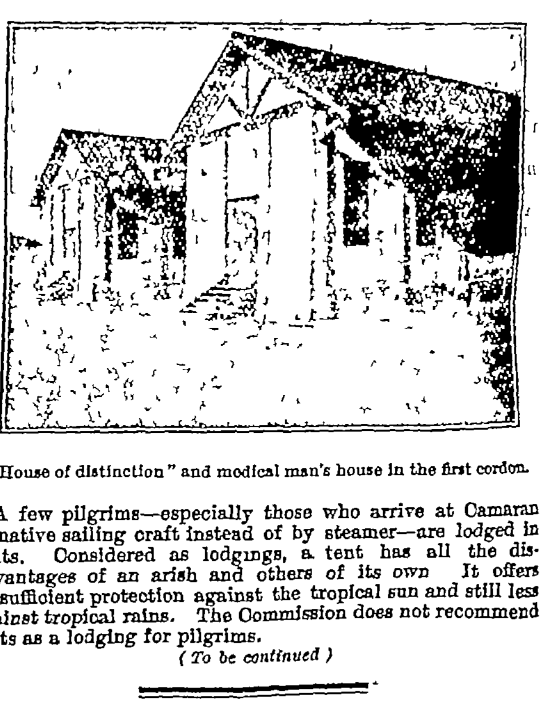
"Specimen house" in the fourth cordon

The kind of house which the Commission recommends for pilgrims is one built of the stone of the neighbourhood. This is an excellent madreporic stone; it should have no layer of plaster, either outside or inside. A damp-proof course should be inserted near the base of the walls. The roof would be *flat and constructed* of what is known in these regions as "tap-tap" Roofs of this kind are the rule in native houses They consist of wooden planks resting on stout wooden transverse beams; on the planks is laid firstly a layer of native matting; this is covered with a layer of clayey earth, then with a layer of shingle, and above all with a layer of lime plaster. The whole is well beaten down with an iron instrument during several days and it is the sound of this beating that gives to the whole the name of "tap-tap" Such a roof *lasts for many years* without repair; it is damp-proof and heat-proof (good eaves ventilation *should, of course,* be provided). Being flat it is easy by constructing a low parapet round and having an outer stair at one end to convert the roof of the house into a terrace, where the pilgrims can take the air and even sleep at night in the hot weather. In addition, the Commission recommends that the floor of such a house should be well raised on vaults, to permit of aeration underneath it, and that it should be formed of a smooth layer *of cement, to* facilitate cleanliness and disinfection.

In each cordon a "house of *distinction*" has been built, intended for better-class pilgrims. One of these houses is shown in *Fig.* 11. In that illustration two houses are seen and as a matter of fact three such "pucca" houses exist in every cordon. One of the three is usually in one corner of the cordon and is meant to be used as the "hospital"; the other two are usually side by side in another corner of the cordon and are intended to be used one as the medical man's house and the other as a "house of distinction" ("*maison de distinction*"), in which better class pilgrims can be housed apart from the others All *three are nearly identical in* construction, the only differences being that the "hospital" is divided into two rooms without a door of communication; the "doctor's house" has two rooms with such a door, and the "house of distinction" has no inner division at all. Further, the "hospital" is built on vaults and piers of brick, permitting of aeration under the floor, while in the other two buildings the floor-tiles rest on the sand. I shall have occasion in a later article to recur to this question of flooring.

The "house of distinction" and the medical man's house in each camp are indistinguishable from each other from the outside; they are also unpleasantly close to each other for the *practitioner's comfort*; and, moreover, the medical man's house, consisting of two large, bare rooms, without bathroom, latrine, *or water-supply, is* ill *suited for its purpose* For this reason the Commission proposes to build a new smaller house for the medical man *(to be referred to in a* later article) and to convert the existing house into a second "house of distinction." Both houses require repair, and it is recommended to add a verandah to each and to improve the ventilation of both of them.

FIG. 11.



"House of distinction" and medical man's house in the first cordon.

A few pilgrims—especially those who arrive at Camaran in native sailing craft instead of by steamer—are *lodged* in tents. Considered as lodgings, a tent has all the disadvantages of an arish and others *of its own* It offers no sufficient protection against the tropical sun and still less against tropical rains. The Commission does not recommend tents as a lodging for pilgrims.

(To be continued)

THE GERMAN SURGICAL CONGRESS.

(FROM OUR BERLIN CORRESPONDENT.)

THE German Surgical Association held its annual meeting in Berlin from April 3rd to 6th, Professor RIEDEL (Jena) being in the chair. After the inaugural business, of which a eulogy on the late Professor von Bergmann and the reading of the address to be presented *by the* association to its honorary member, Lord Lister, were the principal features, the proceedings began with a discussion on

Wounds of the Heart.

Professor REHN (Frankfort) said that wounds of the heart must be sutured and that it had been proved in many instances that *the heart was not necessarily injured* by operative interference. In the course of the application of the *sutures* it might be drawn out through an opening in the thorax, it might be fixed by a loop of ligature

---

[1] For this report we wish to tender our sincere thanks to the editor of the *Deutsche Medizinische-Wochenschrift*, through whose courtesy it has been forwarded to us by our Berlin correspondent.

thread, or it might be seized by toothed forceps, and all this might be done without producing stoppage of the cardiac action, although in some cases the muscular substance quivered when the needle carrying the suture was inserted. The diagnosis of a wound of the heart was, as a rule, not very difficult to make; it might be inferred from the position of the entrance-wound, from the direction of its track, and from the hæmorrhage. The diagnosis might even in some cases be ascertained by radiography. If the cardiac wound was not sutured death eventually occurred from compression of the heart by the hæmorrhage within the pericardial cavity, which could not contain more than from 150 to 200 cubic centimetres of blood without producing grave symptoms. Professor Rehn then explained that the filling of the pericardial cavity led to a compression of the atonic auricles, to an increase of the pressure in the veins, to anæmia of the coronary arteries and plethora in the coronary veins, and in this way to an increasing debility, and finally to stoppage of the cardiac action. The clinical symptoms were pain in the cardiac and epigastric regions, difficult respiration, cyanosis, pericardial friction, and an extension of the area of cardiac dulness. Needles impacted in the tissues might be drawn out, but knife-blades and daggers must be left in the wound until all arrangements were made for exposing the heart, because they tended to stop hæmorrhage by acting as an obstruction. The question whether an operation was indicated or not must be decided according to the circumstances of each individual case. Wounds of the heart might heal spontaneously, but the cicatrix had sometimes broken down afterwards. The operation must begin by an intercostal incision and resection of one or more ribs. If the pleura was not included in the original wound the surgeon should endeavour to preserve it intact. Hæmorrhage must be avoided as much as possible, but it often occurred after incision of the pericardium. Hæmorrhage could be stopped by drawing the heart out of the wound and compressing the vena cava inferior and even the auricles. It had been proved by experiments on animals that this might be continued for one and a half minutes without harm. The suture of the wound of the heart must be done with round needles and silk and not with catgut or wire. When cardiac failure was imminent the operation must be interrupted for some minutes.

Dr. SAUERBRUCH (Greifswald) said that he had made experiments on the influence of pneumothorax on wounds of the heart. He was of opinion that the hæmorrhage from the wound might cease, but that cardiac failure might ensue after a few minutes. He described several experiments showing that by means of his apparatus (some account of which was given in THE LANCET of May 7th, 1904, p. 1308), the lungs became inflated and the heart recovered; moreover, the pleura was less liable to become infected. He recommended that the heart should be sutured under a slightly reduced atmospheric pressure and that afterwards when the pleura was to be closed the pressure should be greatly reduced.

Dr. TIEMANN (Jena) showed a patient who had recovered after the right auricle and the right ventricle had been injured and the pleura opened by a needle penetrating through the fourth intercostal space.

Dr. GOBELL (Kiel) said that he had avoided pneumothorax by the application of Potain's apparatus; it might also be avoided by fixing the pericardium by sutures round the wound. He had proved experimentally that infarct, keloid, and even aneurysm of the heart might be caused by the sutures.

Dr. KÜMMELL (Hamburg) said that he had used direct massage of the heart in syncope occurring during general anæsthesia, after having made the heart accessible by a pericardial incision. Under massage of the heart the patient's lips again became red, the beating of the heart was renewed, and some respirations occurred, but all these phenomena soon ceased and death finally ensued.

Operations for Aneurysm.

Professor LEXER (Königsberg) read a paper on ideal operations for aneurysm. He said that an operation might be called ideal when the sac of the aneurysm was successfully removed, the circulation in the vessels being at the same time preserved. He obtained an excellent result in a case of arterio-venous aneurysm of the popliteal vessels by resecting both vessels and joining the divided ends. The resection left a gap of five centimetres between the ends but this deficiency was supplied by means of a metallic appliance. Immediately after the operation the pulse could be felt in the posterior tibial artery; nine months later, however, the pulse was less distinct because the lumen of the artery was compressed by cicatrices, but no interference with the circulation had occurred. In another case of aneurysm of the subclavian artery a gap of seven centimetres existed after the resection which he tried to fill up by the implantation of a piece of the patient's saphenous vein. Circulation was at once restored, but after five days the patient became delirious and died. At the necropsy it was found that no thrombus was present within the implanted piece.

Dr. STICH (Breslau) said that he had made experiments on the transplantation of arteries and veins of one millimetre in diameter from one animal to another and had succeeded in obtaining complete union of the implanted piece without disturbance of the circulation. In a dog he had cut the renal vessels, ligatured the central ends, and joined the peripheral ends with the iliac vessels; the implantation succeeded and the kidney continued to secrete urine. When the dog was killed several months afterwards no important alterations in the implanted parts were found. In the same way he had implanted the thyroid artery and vein of a dog into the carotid artery.

Operations on the Lungs.

Professor FRIEDRICH (Greifswald) said that the results of operations for tuberculous disease and actinomycosis of the lungs have been unsatisfactory but that they have improved in cases of echinococci and especially in gangrene. In acute cases of gangrene the prognosis was good but in chronic cases it was bad, especially when a resection of several ribs and of considerable parts of the lungs became necessary. The determination of the position of the gangrenous area was difficult though it was now facilitated to some extent by radiography; it was also difficult to decide whether adhesions of the pleura existed. Professor Friedrich recommended that the surgical intervention should be completed in one operation as soon as the existence of a circumscribed abscess in the lung had been ascertained. The lung was fixed by sutures after the resection of the ribs. He preferred to make the opening into the lung by cutting instruments rather than by means of the thermo-cautery, the hæmorrhage being stopped by ligatures. If the abscess was not found at once a provisional plugging was advisable as the pus was often discharged spontaneously after some time through the opening. The proportion of recoveries was about 70 per cent. in localised gangrene. The prognosis was unfavourable in the case of the abscesses of bronchiectasis because the patients were less resistant and the abscesses, as a rule, were multiple. With regard to operations for primary tumours of the lungs, the experience hitherto acquired was not sufficient to enable a definite opinion to be formed. In 73 cases of tumour of the thoracic walls extensive resections of the ribs were performed and 27 cases terminated fatally. In injuries of the lungs those complicated by profuse hæmorrhage might be operated on. With respect to the use of Dr. Sauerbruch's apparatus for reducing the atmospheric pressure, Professor Friedrich was of opinion that its advantages consisted (1) in the ease with which a view of the entire lung might be obtained through the incision and (2) in the possibility of resecting a rib in it without producing pneumothorax. Possibly in the future an exploratory thoracotomy would be as easy as an exploratory laparotomy was at present. It had, however, certain drawbacks, such as the high temperature within the chamber and the limited space, making it difficult for the surgeon and his assistant to move. General anæsthesia was necessary only at the beginning and at the end of the operation. The costal pleura was the most sensitive of the structures implicated, the pulmonary pleura was less sensitive, and the substance of the lungs, the pulmonary vessels and the distal parts of the bronchi were totally devoid of sensation. The maximum duration of operations performed in Dr. Sauerbruch's chamber was one and a half hours. The cyanosis as a rule increased. When pneumothorax occurred suddenly the pulse at once became irregular; the bending at the hilum of the lung made the respiration cease and the pulse disappear. Professor Friedrich recommended that ligatures should not be applied en masse in the resection of portions of the lungs but that the vessels and the bronchi should be isolated individually. The total resection of one lung was impossible because of the impossibility of tying the bronchus in a trustworthy way and of avoiding the occurrence of emphysema of the posterior mediastinum by a loosening of the ligature.

Dr. **LENHARTZ** (Hamburg) reported a lengthy series of cases of pneumotomy of which 85 were performed for gangrene, five for abscesses, 11 for bronchiectasis, and four for cancer. Recoveries followed in 53 of the cases of gangrene and in four of the cases of abscesses, the remainder terminating fatally. With respect to the diagnosis of cancer in the lungs, he said that four points should always be regarded—namely, the presence of cells showing fatty degeneration, which were characteristic; the evidence supplied by radiography; and the results of physical examination and exploratory puncture. He had operated on four cases out of 23, of which one was temporarily successful. All the operations were performed without Sauerbruch's chamber which he believed could be dispensed with. Pneumothorax might occur afterwards when the dressing was changed. He always operated in two stages, resecting the rib at the first operation and incising the lung at the second one. He drew attention to the fact that syncope and even death might occur at the moment when the pulmonary pleura was cauterised.

Professor **KÖRTE** (Berlin) confirmed the latter observation. As the result of 41 operations on the lungs which he had performed he had come to the conclusion that the diagnosis of these conditions was not easy. When there were multiple foci of disease the operation was often very difficult and the prognosis was bad. He said that nothing which he had heard in the discussion had convinced him of the utility of Sauerbruch's chamber.

The **PRESIDENT** asked whether the great hospitals and universities were under a moral obligation to purchase Sauerbruch's chamber, the price of which was still extremely high—namely, from 15,000 to 18,000 marks (from £750 to £900).

Professor **FRIEDRICH** in his reply repeated that the number of cases was still too small to allow of a definitive judgment being formed. Abscess and gangrene of the lungs might be operated on without Sauerbruch's chamber, for brilliant results had been obtained by Professor Lenhartz and Professor Garré without it.

Dr. **SEIDEL** (Dresden) recommended as an alternative to placing the walls of the lung under reduced atmospheric pressure that the bronchial system should be subjected to increased atmospheric pressure as already recommended by Professor Petersen; the pulse, the respiration, and the blood pressure were not altered in the circumstances.

Dr. **SAUERBRUCH** replied that the right ventricle and auricle were damaged by this method.

Professor **KÜTTNER** (Marburg) said that he had performed several operations under increased atmospheric pressure and that he was well satisfied with the results.

Professor **SCHLANGE** (Hanover) said that in severe hæmorrhage from a tuberculous lung he resected the third rib as quickly as possible under local anæsthesia. He then loosened the apex of the lung, drew it out of the wound, and plugged the cavity. The hæmorrhage was stopped by the plugging, but, of course, no influence was exerted on the progress of the tuberculous process.

Professor **KAREWSKI** (Berlin) read a paper on Actinomycosis of the Lungs. He said that he had operated on four cases, of which three had terminated fatally. In his opinion only primary actinomycosis of the lungs was suitable for operation while the disease was still in an early stage and the infected focus was removeable. Metastatic actinomycosis was not operable. An early diagnosis was essential before the thoracic walls were attacked by the disease. With regard to the difference between actinomycosis and tuberculous disease of the lungs, he pointed out that actinomycosis was especially liable to attack the lower lobes. Fibrinous discharge and especially the presence of actinomyces in the sputum suggested the diagnosis; radiography was also of some assistance.

Dr. **MERTENS** (Breslau) said that he had obtained a good result in a case of punctured wound of the lung with profuse hæmorrhage by resecting a rib and suturing the injured part with catgut sutures.

(To be continued.)

GRESHAM COLLEGE.—Four introductory lectures will be delivered on May 14th, 15th, 16th, and 17th by Dr. F. M. Sandwith, Gresham Professor of Medicine, at 6 P.M. The subjects are as follows: Lectures I. and II., "Sir Thomas Gresham and his Times"; Lecture III., Influenza; and Lecture IV., Cerebro-spinal Fever (Epidemic Cerebro-spinal Meningitis or Spotted Fever).

THE MILK-SUPPLY OF LONDON: SOME PERSONAL OBSERVATIONS UPON ITS RAILWAY TRANSPORT.

(FROM A CORRESPONDENT.)

III.[1]

The Midland and London and South-Western Railways.—The Great Northern Railway.—The London and North-Western Railway.—The Great Eastern Railway.—The South-Eastern and Chatham Railway.—The London, Brighton and South Coast Railway.

THE Midland Railway carries a very large quantity of milk to London, the greater part of which is brought from Derbyshire, North Staffordshire, Nottinghamshire, Bedfordshire, and Leicestershire. The milk brought into London by this railway is largely delivered to the suburban stations at Kentish Town, South Tottenham, Hendon, and Cricklewood; that reaching the terminus is delivered at Somers Town, the name given to that part of St. Pancras station used as a goods station. Here there is a special depôt for the unloading of milk and other perishable commodities. Two special milk trains are run by this company, one of which arrives by night and the other at noontime. These trains are made up on an average of 20 vans, each of which will contain about 50 cans of milk, although the usual load is about 30 cans. The milk vans are almost all of one pattern and are of comparatively recent construction. They are well ventilated and the ventilating interstices are covered on the inside by gauze wire to exclude dust and dirt. The great bulk of the milk conveyed to London by the Midland Railway comes by the special milk trains, but milk vans are attached occasionally to passenger trains and small quantities of milk are carried in the guard's vans of passenger trains.

The London and South-Western Railway conveys much milk to London, chiefly from Somersetshire and Dorsetshire. This company runs special milk trains which arrive by night and in the morning, and these are unloaded at Waterloo and Vauxhall stations. Many of the vans are specially constructed for carrying milk, roomy, and efficiently ventilated, but some are old passenger train guard's vans which by their external appearance do not strike an observer as particularly well adapted for the purpose to which they have been put. The London and South-Western Railway carries the bulk of the milk conveyed on its system into London itself into Vauxhall station. 1500 cans daily come into Vauxhall station, chiefly carried by special milk trains, two of which come in during the morning and three by night. A considerable amount of milk is also conveyed by special vans attached to ordinary trains and by the guard's vans of ordinary trains. A great deal of the milk brought into Vauxhall station is transferred to Battersea and Chelsea, and to some other points, while a goodly portion [illegible] the milk brought into the London district by the London and South-Western Railway is deposited on the way at suburban stations, as Wimbledon, Surbiton, and Clapham Junction. The milk traffic on the London and South-Western system has greatly increased during the past few years.

To the main terminus of the Great Northern Railway at King's Cross a large quantity of milk is brought daily, though not so much as to Paddington. The greater part of the milk comes from Derbyshire and North Staffordshire, so that most of it has to travel a greater distance than is the case with the bulk of the milk brought into London by the Great Western Railway. Still, the distances traversed are not very great, for the farthest point from which milk is transported to the metropolis by the Great Northern Railway is between 140 and 150 miles. In the course of 24 hours two special milk trains are run at a rapid rate, which arrive in London during the early morning. One of these trains leaves Stafford at 6.40 P.M., picks up milk *en route*, and gets into King's Cross at 1.36 A.M., occupying about seven hours on the journey, the other is not quite so rapid. These trains account for the greater part of the milk carried by this company, although a certain amount is transported in the vans of passenger trains, but much of the milk brought into London by the Great Northern Railway is deposited at Finsbury Park and other outlying stations, whence it is distributed to suburban districts. When the milk is unloaded at a suburban station it is deposited upon, as a rule, much cleaner premises, but at King's Cross, as at Paddington, the milk in the special trains is unloaded at a milk wharf, constructed especially for the purpose. I watched the arrival of two of the Great Northern milk trains. Although the sole purpose of these trains was the conveyance of milk, some of the vans used were the ordinary vans employed for passengers' luggage, though more were the North Staffordshire Railway milk vans. These are constructed on a similar plan to the milk vans of the Great Western Railway, with open boarded sides. Some of these vans were of a type recently introduced. They were long vans divided into two compartments, each of which can carry 40 milk cans, and the methods of ventilation seemed to be fairly effective. I observed on the Great Northern milk wharf that many of the cans containing milk had their lids partly open and the surface of the milk was in one case filthy.

---

[1] Nos. I. and II. were published in THE LANCET of April 20th (p. 1116) and 27th (p. 1189), 1907, respectively.

The London and North-Western Railway carries a certain amount of milk to London from very remote districts, but the greater part of the milk brought into London by this line comes from localities lying within an easy journey, Buckinghamshire and Hertfordshire being chiefly drawn upon. The bulk of the milk which comes to Euston Station, like that which reaches Paddington, is conveyed by special milk trains arriving by night and in the morning. The vans used for the transport of milk by this company vary considerably both in size and in construction. There are now in use on the London and North-Western system corridor trains for the carriage of milk, the vans of which have efficient ventilation; indeed, the corridor scheme of construction possesses many advantages for the transport of milk. I saw one of these new corridor trains; it was made up of a somewhat novel type of milk van 50 feet in length, 8 feet in width, and 7 feet 10 inches high in the centre. For cooling and ventilating this van 12 torpedo ventilators are placed in the roof to extract the air and at a height of five feet from the floor level are louvred ventilators, protected by perforated zinc, to keep out the dust. The floor is covered with sheet lead, and the sides to a height of three feet are sheathed with stout zinc sheets. The chief and distinctive feature of such vans, however, is that they can be operated singly or may be coupled together to form a train, for which purpose they are provided with gangways, and in order to minimise delay at stations a truck is provided in each van so that the milk can be sorted *en route*. The advantages claimed for corridor milk trains over ordinary milk trains are the greater facility with which milk can be sorted *en route* and the better means which they provide for loading and unloading. I watched the incoming of an ordinary milk train at this station. It arrived at Euston at 11.45 A.M. This train consisted of ten vans of different types of construction. One of these was a long van built in two compartments, resembling externally the two-compartment vans in use on the Great Northern Railway, the capacity of the vans being about the same. Four vans were close boarded, two were lofty vans with side ventilation, and two were ordinary passenger guard's vans. This train came from Gloucestershire and Worcestershire, picking up milk on the way; and judging from the labels on the vans some of the milk had come from a considerable distance, much farther than made the use of passenger guard's vans prudent. It is possible that in the summer heat a better arrangement is made. A considerable quantity of milk is obviously brought into London by the London and North-Western Railway in the vans of passenger trains. I witnessed the arrival of trains from long distances, from the luggage vans of which cans containing milk were put out—20 cans were put out from a Fleetwood train, for example. It does not follow that the milk had been carried from Lancashire to London—indeed, it is more likely that it had been collected *en route*. But this would imply a stopping train, which is equivalent for the purposes of milk transport, when one of the essentials is economy of time, to a long journey. It does not matter much whether milk has been carried 60 miles or 120 miles if in each case the same time is occupied on the journey. I also saw a passenger train arrive at Euston from Nuneaton at about 11.30 A.M., from the guard's van of which cans containing milk were unloaded. This sort of thing I saw on each of several visits paid to Euston Station recently, where there is also a large quantity of cans containing milk standing on certain of the passenger platforms. I must repeat monotonously that the lids of some of these cans are invariably partially open. At Euston, as at Paddington, on more than one occasion I have seen milk poured from one can to another can on the platform. If this is a daily routine the reasons for the dangerous process ought to be removed by proper coöperation on the part of consigner, consignee, and railway company; it is little short of disgusting that on the platform of a railway station, where dust and dirt are notoriously abundant, the staple food of children and invalids—a food which is obviously susceptible to rapid deterioration—should be decanted from receptacle to receptacle. Possibly a comparatively small quantity of milk is thus treated, but the toleration of such a practice shows that some of those commercially interested in the transport of milk have yet to learn the alphabet of scientific cleanliness.

The Great Eastern Railway conveys milk to London from Norfolk, Suffolk, Essex, Lincolnshire, Hertfordshire, and Cambridgeshire. It is carried in special milk vans attached to ordinary passenger trains. The milk vans which I saw at Liverpool-street Station had a capacity of about 70 cans, the average contents of each can being about 16 imperial gallons. I was informed that ten milk vans or thereabouts enter Liverpool-street Station during the 24 hours, which would make 11,000 imperial gallons in the course of a day. The farthest distance from which milk is brought to London by this line is not much more than 100 miles, and the average time taken by the milk vans on the journey is four hours. Sometimes one van is attached and sometimes two vans are attached to a train. Milk is collected *en route* in varying quantities. It appeared to me from my brief inspection that the milk traffic on the Great Eastern Railway was well managed. Of course, the volume dealt with is small compared with that manipulated by some of the other railway companies, but all that I saw impressed me favourably. The milk vans were well constructed and efficiently ventilated, and considering the shortness of the journey from the eastern counties to London there should be little fear, so far as the railway transport is concerned, that the milk would not arrive in good condition. I understand that consigners of milk by the Great Eastern Railway are generally well satisfied with its methods of transport; the only disagreement which has arisen between dairy farmers sending milk by this route and the railway company has been as to the rates for carriage. However, this has been, and is still, more or less a bone of contention between all the railway companies and consigners of milk, and from what I heard I could not see that there were any especial grounds for the complaints of the farmers of the eastern counties.

The South-Eastern and Chatham Railway carries milk into London Bridge, Charing Cross, and Victoria stations, milk being also put off at Woolwich, Dartford, and New Cross. Practically all the milk conveyed by this company is carried by passenger trains, but the amount brought in is small as compared with the other important railways. The milk conveyed to London and the suburbs by this line is, for the most part, sent in small consignments and comes, of course, principally from Kent, Surrey, and Sussex. The greater part of the milk carried into London itself by this route comes to London Bridge Station, but the whole amount thus transported is not large. That conveyed into the South-Eastern and Chatham Railway station at Victoria is small in quantity, but in the summer a considerable amount of milk, from 90 to 100 cans daily, is despatched from this station by passenger trains to seaside resorts.

At the present time a very insignificant quantity of milk is brought into Charing Cross Station. Since the accident to the roof of this station some 18 months ago the milk traffic has declined greatly, but a large quantity of milk is carried to Woolwich and Dartford. The suburban milk traffic of this line is far larger than the metropolitan.

The London, Brighton, and South Coast Railway conveys milk from different parts of Sussex into London and the suburbs in special milk vans and in the guard's vans of passenger trains. The large consignments are carried in special vans and the small consignments are frequently carried in the guard's vans of passenger trains. This line, though deriving its milk traffic almost entirely from Sussex, also carries a certain amount of milk from adjacent districts in Kent and Surrey. Almost the whole of the milk conveyed to the London district by the London, Brighton, and South Coast Railway is left at suburban stations situated between Croydon and Sutton. A relatively large amount of milk is deposited at Croydon itself. The time taken by trains travelling by this route carrying milk to reach London and the suburbs is not, as a rule, longer than one and a half hours.

In some respects the conditions in regard to milk transport by the South-Eastern and Chatham Railway and by the London, Brighton, and South Coast Railway are similar. Both lines carry milk into London and the suburbs from comparatively short distances and both deposit the greater part of their milk cargo at suburban stations. Passenger trains are employed by both lines to transport milk, more so by the South-Eastern and Chatham Railway than by the London, Brighton, and South Coast Railway. The milk cans are unlocked and unsealed, which doubles the risk of carrying the fluid in the guard's van of a passenger train.

(To be continued.)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

St. John Ambulance Work.

THE annual competition in connexion with the North Western District Nursing Division of the St. John Ambulance Association took place at Blackpool on May 4th. This very useful association covers a wide area, as shown by the sections examined coming from Liverpool, Rochdale, Lytham, Preston, Accrington, Bolton, Castleton, Brierfield, Bury, Crompton, Barrowford, Oldham, and Nelson. The trophy offered was a silver shield which was presented to the association in 1902, in which year and also in 1903 it was won by Blackpool. Since then it has been won by Lytham, Rochdale, and Blackpool in chronological order. Winning in 1906 Blackpool did not compete this year, when Brierfield came out first, Lytham second, and Nelson third. The examiners and judges were Dr. J. W. Johnstone of Bolton and Dr. J. Broomhead of Haslingden. It is difficult to estimate the good that is done in this way; we may be sure, however, that it is not limited to the winning teams but that a leaven of sanitary growth is working far and wide through the manufacturing districts of Lancashire where it is so much needed.

Royal Albert Asylum, Lancaster.

It is now more than 40 years since the Royal Albert Asylum at Lancaster was opened for the treatment of all improvable grades of the feeble-minded in the northern counties of England. It was established, and is chiefly maintained, by public subscription and there is now accommodation for 700 inmates. At present there are about 650 patients and the election for this year's applicants will take place at the County Hall, Carlisle, on Wednesday next. The objects and methods of the institution will be explained and specimens of work done by the patients will be exhibited. For the 50 vacancies there are 83 candidates—a fact which shows not only the great need that there is for such an institution but also the confidence of the public in intrusting those whose mental strength is feeble to the judicious and kindly training given at the asylum. The committee appeals for donations and subscriptions, as a large addition to the annual income is needed if full advantage is to be taken of the existing accommodation. Of the present inmates 269 belong to Lancashire, 72 of them coming from the Manchester and Salford district. In connexion with this forthcoming election a meeting of the Manchester local committee and the members of the Manchester and Salford District Ladies' Association was held in the Memorial Hall on April 30th. The secretary, Mr. Keir, said that the district was still deeply indebted to the institution for the maintenance and training of the patients whom it sent. The returns of the District Ladies' Association, though not yet complete, compared favourably with those of last year and a substantial increase in the amount collected was anticipated. On behalf of the central committee Mr. Keir thanked the members of the local committee for their services. It is to be hoped that the efforts made will take away the reproach that the Manchester district does not provide sufficiently for the patients whom it is so glad to safeguard in the asylum.

University of Manchester.

Interesting developments are taking place in the University of Manchester. One of them is perhaps only indirectly connected with medicine but is interesting on its own account. It has been decided to appoint lecturers in economic zoology and economic botany. They will investigate the life-history of animal and vegetable pests and will inquire into definite instances of damage done by pests which are brought to the notice of the University by local authorities, by farmers, or others. This branch of work is in many respects analogous to that carried on in the field of bacteriological research by the public health department of the University under Professor S. Delépine. Lectures on their subjects will be given in the University by the new members of the staff. Improved facilities for teaching experimental psychology are also receiving consideration by the University authorities, and indeed the appointment of a teacher in this subject is only awaiting the possession of sufficient means. It is thought that this appointment will have an important influence on the investigation of mental and nervous diseases and likewise on the study of the conditions of school life and the mental development of children.

Manchester Jewish Hospital.

The board of the Manchester Jewish Hospital has appointed Dr. Julius Dreschfeld and Dr. Judson Bury as honorary consulting physicians.

Pulmonary Tuberculosis at Rochdale.

During the last half century the deaths from pulmonary tuberculosis at Rochdale have fallen to 1·32 per 1000, being 2·33 per cent. lower than the rate at the beginning of the period. This reduction is something to be thankful for but not to rest satisfied with.

Manchester Royal Eye Hospital.

The Manchester Eye Hospital is to be enlarged at an estimated cost of £23,000. 50 more beds for patients will be provided, making a total of 160, a number expected to meet all requirements for a long time to come. The old hospital in John-street is retained for out-patients, and the two out-patients' departments treat about 30,000 cases annually.

Lead and Soda-water.

An inquest was held on April 30th on the body of the wife of a Manchester fruiterer. She had been ailing for some time and had suffered some pain. To relieve this she took several draughts of soda-water from the soda-water fountain in the shop, but as she grew worse Dr. Saul and Dr. Helm were called in and advised her removal to the Northern Hospital, where she died. Dr. Helm said that the cause of death was lead poisoning, and on analysing a sample of water from the fountain he found that it contained seven grains of lead per gallon absorbed from the lead piping attached to the machine. The verdict was "Death from lead poisoning" and the jury recommended the inspection of all the machines of the kind in the city. It would have been quite justifiable if they could have ordered the destruction of all such machines. The knowledge of the very easy contamination of water by lead is now so general that it is scarcely possible to imagine the manufacturers of these dangerous fountains having preserved their ignorance of this fact intact, more especially in regard to water charged with carbonic acid. It becomes, therefore, a question as to their position legally and morally when they turn out for public use these fountains for distributing lead and soda-water.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Port Sanitary Authority.

ALTHOUGH at the time of its establishment the Cardiff and County Public Health Laboratory was criticised as involving an unnecessary and useless expenditure of public funds, every year the advantages of such an institution are more apparent. Nowhere are these more clearly shown than in the work done in the laboratory for the port sanitary authority. On several occasions, though happily the necessity did not arise in 1906, the diagnosis of plague has been speedily verified, so that justification has been found for the subsequent drastic measures which have prevented any spread of the disease. This ability to deal speedily and successfully with such a disease as plague must give a sense of security to all those who are engaged in the shipping business of the port and it is beginning to be realised that the expenses connected with the administration of the port sanitary authority are a form of insurance against the losses—and they might assume large proportions—which would follow the almost certain neglect of the port by ship-owners should an outbreak of infectious disease become unmanageable. The reputation which the Cardiff Port Sanitary Authority is justly earning for dealing promptly and successfully with any such outbreak ought to be reckoned among the assets of the town. In 1906 the assistance rendered to the port sanitary authority by the public health laboratory appears to have been confined to the bacteriological examination of samples of drinking water taken from vessels entering the port. Altogether 90 such samples were examined and of this number seven were stated to be very impure, 48 impure, 24 fair, and 11 good. Of the 12 samples examined during October all but two were found to be either impure or very impure.

Typhoid Fever in Swansea Rural District.

At the last meeting of the West of England and South Wales Branch of the Incorporated Society of Medical Officers of Health an interesting account was given of the recent outbreak of typhoid fever at Gorseinon in the Swansea rural district by Dr. William Williams, medical officer of health of the Glamorgan county council; Dr. Trafford Mitchell, one of the medical officers of health of the rural district; and Dr. H. A. Scholberg, the bacteriologist to the Cardiff and County Public Health Laboratory. The epidemic was thus dealt with from more than one point of view. Gorseinon is a scattered industrial district where the insanitary conditions too often found in such areas are in evidence. The outbreak started in September, 1906, with two cases, each of which, though doubtful clinically, gave positive Widal reactions. Then followed a group of five cases around a contaminated well, all of the patients affected being relatives of the first case. A systematic examination of all cases of pyrexia was then instituted, with the result that several ambulatory cases were discovered. Family relationship was evident in every group. In every family tested for the Widal reaction there were positive results in one or more instances. The ambulatory character of the epidemic is evidenced by the fact that 62 of the 100 cases were diagnosed in the consulting-room. The blood of many "contacts" was examined, but a positive reaction resulted only where clinical symptoms were present. Personal infection appeared to be a considerable factor in causing the spread of the disease. Two medical officers who were engaged in coping with the epidemic developed the disease in its ambulatory form. There was some evidence in favour of the disease being spread by means of the public elementary schools and they were accordingly closed for a period. The water-supply was derived from 20 wells, only one of which was found to be contaminated.

A Proposed County Medical Officer of Health of Monmouthshire.

In recent reports upon the condition of certain sanitary districts of Monmouthshire medical inspectors of the Local Government Board have recommended the grouping of districts for the purpose of appointing a whole-time medical officer of health. These recommendations have led the county council again to consider the desirability of appointing a medical officer of health for the county. There is no doubt that this official ought to have been appointed years ago. There is ample work for him to do in the rapidly increasing colliery districts of the county.

The Meat-supply of Plymouth.

At a recent meeting of the Western Counties branch of the Veterinary Surgeons' Association held at Plymouth remarks were made on the alleged insufficient inspection by the local authorities of the meat-supply, in consequence of which carcasses were brought into the "Three Towns" in a diseased condition and animals unfit for human food were slaughtered in the private abattoirs and sold at the small shops. A considerable discussion arose over the matter in the local press. A meeting of the Plymouth markets committee of the town council was held to consider the subject and it decided to ask the Veterinary Surgeons' Association to give instances of diseased meat having been brought into Plymouth or of diseased animals having been slaughtered in the town and exposed for sale. The association in its reply stated that the allegations made were not meant specifically to apply to Plymouth but generally, because the members of the association had it within their knowledge that such things did occur in large cities. The markets committee felt that the reply was not satisfactory and decided that inquiries should be carried further; it also determined that the whole matter should be referred to the medical officer of health who will report the result of his investigations.

The Royal Mineral Water Hospital, Bath.

The annual meeting of the governors of the Royal Mineral Water Hospital, Bath, was held on May 1st, under the presidency of the Rev. H. Winwood. The medical report stated that 1185 in-patients had been admitted during 1906, compared with 1161 in 1905. The average daily number of occupied beds was 145. The financial statement showed that the ordinary income amounted to £4881, while the ordinary expenditure was £5095, leaving an unfavourable balance of £214 Colonel M. Ricketts was elected president for the ensuing year.

May 6th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Extension of the Glasgow Samaritan Hospital.

LAST week Lady Blythswood opened the new wing and extension just completed of the Glasgow Samaritan Hospital for Women. The new wing contains four large wards with accommodation for ten beds each and four smaller wards with accommodation for three and two beds each, two large convalescent rooms, and two well-equipped operating theatres. The administrative block between the old and new wings has also been entirely remodelled. The cost of building and furnishing the new wing, together with other additions and alterations, amounts to over £12,000, while the total cost of the whole hospital buildings, including nurses' home and dispensary, has been about £40,000.

Report of the Glasgow Hospital for Skin Diseases.

The annual report of this institution shows that during the past year 1742 new cases were treated at the hospital, making 61,496 since its foundation in 1861, while 103 of the more serious affections were admitted to the wards of the Western Infirmary which are in connexion with the hospital.

Greenock Meat Inspection Inquiry.

On account of dissatisfaction expressed as regards the methods employed in dealing with the carcasses of animals slaughtered at Greenock the Local Government Board several weeks ago instituted an inquiry into the procedure in use in the slaughter-house there. Dr. F. Dittmar in his report states that there are evidences of great slackness having been permitted for years past in the system of meat inspection. The report covers a period of ten years, and after going into the statistics of carcasses condemned during that time he points out that as compared with Glasgow the percentage of condemned carcasses is too large. He also holds that the tripery and the digestor at the slaughter-house, together with the feeding of the animals, should be in the hands of the corporation and not of private individuals. It is also suggested that a veterinary surgeon should be appointed to give his whole time to the work, as well as two meat inspectors and a cleaner.

The Northern Infirmary, Inverness.

The annual meeting of the managers of the Northern Infirmary, Inverness, has just been held, ex-Provost McBean presiding. Mr. Duncan Shaw, W.S., honorary secretary, gave in the annual report. The installation of the electric light has now been completed and it is hoped that the apparatus for electrical treatment will soon be placed in the infirmary. A new water-supply has been introduced into the convalescent home at Bona. Reference was made to the lamented death of the Rev. Dr. Black, who was a manager for a long number of years, and of Mr. Charles Marshall Brown, the honorary secretary. Considerable discussion took place with regard to the admission of patients suffering from pulmonary tuberculosis into the infirmary, and ultimately a motion was carried to the effect that the present arrangement as to the admission of such patients should be continued for one year from this date, but in view of the fact that pulmonary tuberculosis is now an infectious disease by order of the Local Government Board and that provision had to be made by local authorities for such cases, the infirmary will not continue to accept such patients after that date. The financial report for the past year stated that the ordinary revenue for the year amounted to £2294 and the ordinary expenditure to £3663 showing a deficiency of £1369 as compared with an adverse balance of £1166 in 1905. The legacies also showed a considerable decrease on previous years. The net results of the year's working, after applying the legacies to current requirements, showed that the accumulated funds of the institution had been still further reduced by a sum of £1085. The finance committee suggested that the managers might remit to it and the new honorary treasurer when he was appointed, with full powers to carry into effect an arrangement for the collection of subscriptions. The daily number of inmates, including patients and attendants, was 91·8 for 1905 and 89·6 for 1906; patients only, 57·8 for 1905 and 57·6 for 1906. The average duration of treatment of patients in 1906 was 29·3 days, as compared with 30·2 days in 1905. The report was adopted and the managers and committees were appointed.

Scottish Trades Congress: Death Certificates.

At the above congress recently held in Aberdeen the following motion was carried :—

> To instruct the parliamentary committee to press forward legislation to provide that all societies, whether trade union, friendly, or industrial, who pay funeral allowances shall be placed upon an equal footing as regards fees for obtaining certificates of death of members.

The summer session of the University of Aberdeen opened on April 30th.

May 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Dublin.

AT a meeting of the Senate of the University of Dublin held on May 3rd a grace was passed offering the degree of LL.D. *honoris causâ* to the Colonial Premiers at present in England.—A certain gloom has been cast over Trinity College by the death of Dr. John Kells Ingram, some time Senior Fellow and in 1898 Vice-Provost of the College, one of the most distinguished scholars of the University of Dublin during its brilliant Victorian era. When he was an undergraduate he wrote a poem, entitled "The Memory of the Dead," better known now as "Who Fears to Speak of Ninety-Eight?" The modern Nationalists have adopted it as their anthem but Dr. Ingram, I believe, never expressed any sympathy with their aims. He died at his private residence in Mount-street on May 1st.

The Rotunda Hospital.

A charter meeting of the board of governors of the Rotunda Hospital was held on May 3rd, General the Right Hon. Lord Grenfell, G.C.B., being in the chair. After the usual routine business was completed Mr. John William Bell was, on the nomination of the master, unanimously appointed as assistant to the master in the room of Dr. Guy Theodore Wrench, resigned.

The International Exhibition.

The International Exhibition in Ireland was formally opened by the Lord Lieutenant and Countess of Aberdeen on May 4th. They drove in state through the streets of Dublin and were received with cheers. Lord Aberdeen addressed the assemblage at the exhibition and read a gracious telegram from the King wishing success to the venture. On Monday, May 6th, the Marchioness of Ormonde received the officers of the *Britannia*, one of the splendid battleships in the bay, at the hall of the exhibition and presented them with a beautifully engraved ship's bell and many silver ornaments for their mess.

The Health of Belfast.

At a meeting of the city council held on May 1st it was reported that for the four weeks ended the 13th ult. the death-rate in Belfast from all causes was 23·2 per 1000. There is a diminution in the number of the ordinary infectious diseases but, on the other hand, cerebro spinal meningitis still continues, the numbers being practically the same as last month—100 as against 104—and the death-rate from zymotic diseases—1·6—is higher than in the previous month. On May 2nd, at a meeting of the public health committee, it was reported that 20 cases of cerebro-spinal fever had been notified during the week as compared with 36 in the previous week. The death-rate for the week ended April 26th was 23·9 per 100 Of late several cases of cerebro-spinal fever have occur among adults.

The Belfast Health Commission.

The Health Commission has sat continuously from April 25 to May 3rd investigating the question of the purity of t water-supply. Professor E. A. Letts (who objects to t Stoneyford and Woodburn water on chemical grounds), Dr. Alexander and Dr. D. P. Gaussen (who are the dispens medical officers of the Stoneyford area and who showed liability to pollution), Mr. F. McCullough (engineer), and R. Hamerton (secretary of the water commissioners), as w as Professor P. Frankland, Dr. A. C. Houston, and Dr. M. Gordon, who gave evidence on behalf of the water trust, a Mr. Sweeny, an engineer, who thought the water from Ston ford and Woodburn was not above suspicion, were all e mined. The Commissioners have also visited the catchment areas. On May 14th the commission, which is doing its work thoroughly, will again sit in Belfast to hear evidence as to the sanitary state of that city. At the last monthly meeting of the city council (May 1st) reference was made by some of the members to the cost of the health commission, but—and largely, it would appear, owing to the action of the Public Health Committee—the citizens are saddled with the fees of a King's counsel who sits beside the chairman of the Public Health Committee at the sittings of the Commission. The reforming party in the Belfast corporation—who are steadily increasing—have protested very strongly against this expenditure in legal fees.

Cerebro-spinal Fever in Belfast: Dr. M. H. Gordon's Views.

At the sitting of the Belfast Health Commission on April 30th Dr. M. H. Gordon, who has for some time been retained by the Local Government Board (English) to investigate the problems presented by the etiology and treatment of cerebro-spinal fever, gave some remarkable evidence. After alluding to the report which has been issued by his Board on the subject of the meningococcus, and to the bacteriological evidence obtained in America and Germany showing the main cause of the disease to be the micrococcus of Weichselbaum, he stated his view that the people most liable to carry the organism of the disease, and so to infect others, are those who have been in contact with the infected but are themselves well. This view was somewhat modified by a further statement that these mediums for infection might exhibit a mild meningitis, while they are capable of handing the organism over to others who are less resistant, especially children, and so to spread the disease. In Germany it was found, he said, that 10 per cent. of "normal" people in contact with the disease showed what was identified as the meningococcus in their respiratory passages, and in the same epidemic 20 per cent. of the affected showed organisms in the same locality. It was found during the first few days that some 50 per cent. of the patients presented signs of the meningococci in the upper respiratory passages. As these facts have not been noticed by our medical authorities Dr. Gordon suggested that it was necessary in the case of Belfast to have the services of a bacteriologist to devote himself to the question of cerebro-spinal meningitis, so that detailed knowledge might be obtained for purposes of prevention. He pointed out that if the German observations were accurate the isolation of "normal" contacts would have to be made compulsory for the good of the community, and with the example of the methods adopted in the case of diphtheria before him he saw no great difficulty in such a scheme. He rightly declined to assert dogmatically that contacts in cerebro-spinal meningitis should be segregated for any particular period of time, on which question he said that he should prefer to consult Professor W. Osler who was one of the committee which investigated a recent and appalling outbreak of cerebro-spinal meningitis in New York. After mentioning the possibility that without bacteriological investigation the mild respiratory symptoms sometimes present in those whom he termed the "normal" contacts in regard to cerebro-spinal meningitis might be confused with the symptoms of pneumonia—a fact which pointed again to the necessity of systematic bacteriological investigation of all notified cases of cerebro-spinal meningitis—Dr. Gordon, in a properly guarded way, mentioned some investigations, not yet complete, by means of which epidemics of cerebro-spinal meningitis might be prevented. He informed the Belfast Health Commission that the methods to which he alluded, which are at present of a confidential nature, are on the lines adopted when using preventive prophylactics for plague, cholera, and typhoid fever, and added that the few experiments so far made showed the treatment to be harmless and promising. It is only fair to say that the bacteriologists who in Belfast are making most careful investigations of cerebro-spinal fever do not accept Dr. Gordon's views on many points and are sceptical—from their work—of any preventive vaccine or serum being discovered. They have worked direct from the cases and not from any borrowed strains of the meningococcus. The serum sent from Germany has been shown to be useless both clinically and by laboratory experiments, and, what is still more peculiar, the blood from cases of cerebro-spinal meningitis in London does not react to the meningococcus present in the Belfast epidemic; and the cases seen in Belfast are, many of them, clinically quite different from those which under the term posterior basic meningitis or cervical opisthotonos of infants were supposed to be endemic examples of the disease. It will be interesting to note whether the meningococcus of such cases will react to the meningococcus present in the Belfast epidemic. This, of course, goes to suggest that the coccus on which Dr. Gordon bases his observations is not the meningococcus present in the Belfast epidemic.

May 7th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Work of Port Sanitary Authorities.

M. Clémenceau, Minister of the Interior, has recently obtained the signing of a decree by which the rights and duties of port sanitary authorities with respect to vessels arriving in a port are defined. In future every vessel arriving in a port of France or of Algeria must be visited by an officer of the sanitary authority before communicating with the shore, and if such officer has reason to suppose that there is a case of doubtful or febrile illness on board a visit must also be made by a medical officer, who will decide whether the illness is, or is not, one of those contemplated by Article 4 of the law of Feb. 15th, 1902, relative to the protection of the public health. When the medical officer has decided that the illness is of the former class it will be his duty to see that the regulations of the port sanitary authority are carried out with respect both to the vessel and to the persons on board; he will also invite the municipality in coöperation with the crew to remove the patients to the isolation hospital, and in carrying out the measures prescribed either by the law of 1902 or by the local sanitary regulations he may have recourse to the services connected either with the municipality or the department so far as one or other of them is respectively concerned.

Compressed-Air Illness.

At a meeting of the Medico-Chirurgical Society held on April 8th M. Berruyer gave an account of cases of compressed-air illness which had occurred among the men employed in various works in Paris since October, 1905. He explained that there was a material difference between the ill-effects experienced by divers (*scaphandriers, plongeurs*) and by *tubistes* or men engaged in subaqueous work, such as the foundations of bridges. This difference depended on the fact that divers descended to greater depths than were required for subaqueous constructional work, and further, that the conditions of diving were quite unlike those in which the *tubistes* passed into and out of the air-locks (*l'éclusage et le déclusage*). The illness affecting the *tubistes* was known also as caisson disease. It rarely occurred while the men were in the compressed air chambers but showed itself for the most part either during decompression or a few hours afterwards and had a direct relation to the rapidity of decompression, the duration of which ought not to be less than three minutes per atmosphere of extra pressure. The most usual symptoms were violent pains in the limbs, particularly in the lower limbs, sometimes accompanied by temporary paraplegia. M. Berruyer did not observe any instance of aphasia or word deafness or any indication of a cerebral lesion. Disorders of the gastro-intestinal tract, such as vomiting and obstinate constipation, were not infrequent. The respiratory organs might also be involved and cardiac arrhythmia, a symptom not previously recorded, had been observed on several occasions. The illness did not in general exceed 10 or 20 days and none of the cases terminated in death or permanent disablement.

Sad Death of a Medical Man.

Dr. Rabuel, a young medical man practising in Paris, has just died in extremely sad circumstances. Having under his care two patients, a woman and her son, suffering from diphtheria, and both of them dangerously ill, he applied his mouth to that of the child and used forcible suction for the purpose of removing false membrane which was choking the patient. He then employed the same means for the relief of the mother. The condition of both patients improved almost immediately, but two days afterwards the unfortunate medical man had to take to his bed and he died from diphtheria in a few hours. He was married two years ago.

The Campaign against Tuberculosis.

M. Albert Robin delivered a lecture on April 23rd at the Academy of Medicine on a very important and comprehensive scheme for the suppression of tuberculosis and the economic measures by which he has been trying to carry it out. His method is in opposition to the costly and incomplete sanatorium system which swallows up such large sums of money and can only effect the very hypothetical cure of a small number of tuberculous patients, and consists of a set of measures to which he has given practical trial in the anti-tuberculous department that he has established at the Beaujon Hospital; these are free consultations restricted to indigent persons, the distribution of medicines and clothing, educating tuberculous patients and their relatives, attending to the hygienic conditions of their homes and surroundings, sending early cases to the country, securing the admission to the Angicourt Sanatorium of cases likely to be benefited by treatment there, and giving medical and other aid to its patients after their discharge. It also provides for coöperation with different charitable associations of the tuberculous patients of which the department takes charge and which in return help the patients of the department in their several ways. This comprehensive plan has proved practicable without either establishing any new organisation or costing the public funds anything, owing to the great support which it has received from its well-wishers, and it has reduced the cost of effectively treating a tuberculous patient and looking after his surroundings to 7 francs 27 centimes[1] per head per annum, whilst the treatment of a single patient in the sanatorium varies in cost between 4 francs and 5 francs 90 centimes per day. The general adoption of this system in the Paris hospitals would admit of the treatment of 30,000 tuberculous patients a year in this manner and would need at the outside figure an annual sum of 300,000 francs, which is infinitely less than the enormous estimates required by all the other plans.

Death of Professor Poirier.

Professor Poirier has just died at the age of 51 years. For the last six months he had symptoms which made him fear the presence of gastric cancer, and he had taken gradually increasing quantities of morphine; recently he had been submitted to a "morphia cure" at a private institution, but acute failure of the hepatic and renal functions supervened and he rapidly died in coma. Professor Cornil performed a necropsy and found a small nodule of growth in the head of the pancreas but nothing in the stomach. The late professor succeeded Professor Farabeuf in the chair of Anatomy in the Faculty of Medicine, and he had a brilliant career, successively holding the posts of hospital interne, demonstrator of anatomy, *agrégé* professor, and surgeon to the hospitals; for three years he had been a member of the Academy of Medicine. He was a fine worker and leaves behind him a treatise on anatomy which is an important work. His qualities were brilliant and he was a man of wide acquaintance and of a charming personality. He was a representative member of the French medical deputation which visited London in 1904 and his eloquent speech on the occasion of the luncheon given by the Editors of THE LANCET will be fresh in the minds of those who heard him.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Sanatorium Treatment of Tuberculosis.

AT a recent meeting of the Society for Social Medicine and Hygiene, Dr. Grotjahn read a paper on the present crisis in the sanatorium movement. Alluding to the fact that the "committee for the erection of sanatoriums" had changed its name to that of "committee for the prevention of tuberculosis," he pointed out that a reaction against the activity formerly shown in establishing sanatoriums for tuberculous patients had now set in. If it was true that the examination and the treatment of such patients which used to take place exclusively in the consulting-room of the physician were carried out more accurately in a sanatorium, the work of the committee must be highly commended, and if the patients either recovered or if their ultimate breaking down in health was deferred for several years the money spent by the Landesversicherungs-Anstalt (invalidity insurance offices), which amounted to 434 marks (about £22) for each patient, was not laid out unprofitably. There were at present in existence 80 public sanatoriums with 7500 beds for consumptives of the working classes, 13 private sanatoriums with 2000 beds, and 13 sanatoriums for children with 500 beds. The statistical returns show, however, that the proportion of recoveries to admissions was 34 per cent. and that 31 per cent. of the patients became permanently disabled after only five years. It was not likely that these small numbers had any influence on the spread of tuberculosis as such. The number of recoveries was the less satisfactory, as only patients in the very first stage of the disease were received in the sanatoriums. Professor Koch has denied the practical value of sanatoriums, as the decrease of the mortality from tuberculosis had begun previously to the establishment of the sanatoriums; this decrease must therefore be attributable to some other cause or causes, such as, for instance, the improvement of the standard of living among the population. The sanatorium system was undeniably attended with certain advantages, one of these being the fact that the tuberculous patients were isolated from the healthy population, but this result ought to be obtainable at a much lower cost than was the case by the methods at present in use. Owing to the fact that the building expenses of the sanatoriums varied from 3000 to 11,000 marks (from £150 to £550) per bed without counting the outlay for rent, measures must be taken to obtain better results at less cost. Dr. Grotjahn recommended the erection of a great number of small asylums distributed through the country so that every town or considerable village should have one asylum. They ought to be furnished as plainly as possible; the patient after admission being not far from his usual place of residence might be able to work and might therefore remain an inmate of the asylum for a long time and even for life. These asylums for tuberculous patients should be fitted up and managed after the pattern of those existing in Norway for the reception of lepers. The Norwegian leper asylums were 20 in number, each containing from 10 to 15 beds; they were situated in country places and the style of living followed in them was similar to that of an ordinary family in moderate circumstances. The inmates of the proposed asylums for tuberculous patients ought to be provided with opportunities for employing themselves in some kind of work, either indoors or outdoors. The asylums should eventually be joined with agricultural colonies, as was the case in some lunatic asylums. The discussion on Dr. Grotjahn's address was postponed and it is expected that the views which he expressed will be combated by the advocates of the sanatorium system.

Professor von Bergmann's Successor.

It is announced that Professor Bier of Bonn has been appointed to succeed the late Professor von Bergmann as ordinary professor of surgery and director of the surgical clinic at the University of Berlin. Professor Bier is still a comparatively young man, having been born in 1861. Becoming qualified in 1885 he was for several years assistant to the celebrated Professor von Esmarch of Kiel and when this professor retired Dr. Bier was ppointed ordinary professor in the University of Greifswald s the successor of Professor Helferich who had gone t Kiel. In 1903 he left Greifswald for Bonn to replace the late Professor Schede. Professor Bier is known as the discoverer of some important surgical procedures. One of these is the employment of passive congestion, which was devised by him about ten years ago for the treatment of surgical cases of tuberculous disease, and he afterwards made use of it in the treatment of acute inflammation of all kinds. A full account of the method was given by him at the meeting of the German Surgical Congress in 1905,[1] and the innovation was fully approved by the great majority of the surgeons at the Congress held in the following year.[2] Professor Bier is, moreover, the discoverer of anæsthesia by intraspinal injections which has been generally adopted by surgeons. When an appointment to an ordinary professorship in a university has to be made the practice is that the medical faculty of the university in question recommends three candidates to the Government, placing their names in their presumed order of eligibility. In the appointment of a successor to Professor von Bergmann the names proposed to the Government were Professor von Eiselsberg of Vienna, Professor Bier of Bonn, and Professor Garré of Breslau. Professor von Eiselsberg, who is an Austrian and was formerly assistant to the late Professor Billroth, held an ordinary professorship at the University of Königsberg in Germany for several years, but he now declines to leave Vienna. The choice therefore fell on Professor Bier whose appointment will certainly meet with general approval.

May 6th.

Obituary.

EDWARD MARKHAM SKERRITT, M.D. LOND., F.R.C.P. LOND.,

SENIOR PHYSICIAN TO THE BRISTOL GENERAL HOSPITAL.

THE news of the death after a few days' illness of Dr. E. Markham Skerritt of Clifton came as a great shock to the large number of his friends and associates in the profession. He had enjoyed an unusual measure of health for many years and lived such an active and yet methodical and careful life that he was regarded as a peculiarly strong man.

Edward Markham Skerritt was born in Chelsea on Dec. 30th, 1848. He was at Mill Hill School for a short time but on his parents removing to Wokingham he was sent to Amersham Hall School, which had just then been moved to Caversham. On leaving school in 1866 he matriculated at the University of London and in October of that year entered for the arts course at University College and graduated B.A. at the University of London in 1868. He then entered the science department of the College and prepared for the Preliminary Scientific M.B., and in 1869 entered the medical department of the College. He graduated M.B., B.S. in 1873 and took the M.D. degree in 1874. Throughout his student course he was distinguished for his strength of character, independence of thought, and methodical habits. He gained many class prizes and distinctions and won the Atkinson-Morley surgical scholarship, a much-coveted honour, and was subsequently elected a Fellow of his College. At the University of London he carried off gold medals in physiology, in medicine, and in obstetric medicine. He obtained the Membership of the Royal College of Physicians of London in 1876 and was elected a Fellow in 1885. In 1897 he was chosen to deliver the Bradshaw lecture. At the time of his death he was a member of the Council of the College.

In 1875, a few months after obtaining his M.D. degree, he was elected a physician to the General Hospital, Bristol, and settled in consulting practice in Clifton. He held this office for 32 years and had been senior physician for many years. He devoted himself to the work of the hospital with his characteristic punctuality, precision, and thoroughness, and from the first the authorities of the hospital, his colleagues, and his students realised that he was a highly gifted physician whose opinion and teaching were of special value and his influence in the hospital was very great and equally beneficial. For many years he lectured in the school, first on pathology and later on medicine; he was dean of the school for a long period and only recently resigned this office. He took a leading part in the negotiations for the union of the medical school with University College, Bristol, and his sound judgment, clearness of perception, and firmness and courtesy in discussion were of great service.

---

[1] THE LANCET, May 27th, 1905, p. 1455.
[2] THE LANCET, May 26th, 1906, p. 1492.

Dr. Skerritt threw himself with zest into the work of the local medical societies, regularly attended the meetings, often contributed papers and joined in discussions, and his intervention was always especially welcome as his remarks were the clear expression of well-thought-out conclusions. He had been president of both the Bristol Medico-Chirurgical Society and of the Bath and Bristol branch of the British Medical Association. He was one of the local secretaries when the British Medical Association visited Bristol and the success of the meeting was largely due to his unfailing industry and to his skill in arrangement as well as to his uniform genial courtesy. Of late years he devoted much time to the interests of the British Medical Association; he had held the responsible office of treasurer of the Association and at the time of his death was one of its vice-presidents. He was a very regular attendant at meetings of the council and of various committees, and his opinions carried great weight, for he was eminently wise in counsel. He was a member of the Board of Advanced Medical Studies of the University of London and attended its meetings regularly; his opinion was always highly valued, as he spoke from wide experience and had a breadth of view of professional matters that struck all who served with him on committees.

Dr. Skerritt quickly acquired a considerable practice and for many years he had to limit himself to the work of a consultant, except in the case of a few old patients. Practitioners in Bristol and in an ever-widening area around found him always helpful, considerate, and painstaking. He gained in a remarkable degree the complete confidence of his brethren and of his patients and his removal leaves a correspondingly great sense of loss.

Dr. Skerritt was a keen sportsman; for many years he regularly rode to hounds and spent his summer vacations on Exmoor in order that he might enjoy the stag-hunting. He was an excellent horseman, combining care and courage, and he was always welcome in any hunting field. He was a life-long abstainer from alcohol and tobacco. In the early days of his practice, under the influence of the teaching which he had received at his hospital, he prescribed alcohol to many of his patients, but as his experience increased, we are informed, he ordered it less and less and for many years used it very sparingly indeed.

He had all his life enjoyed robust health and took a keen delight in a simple healthy life, with abundant exercise, and perhaps he had come to regard himself as more than usually capable of resisting ills that were serious to others. Until this winter he had never been known to lie up for illness of any kind, but in November last he was laid aside by an attack of influenza from which he seemed to recover completely. On Sunday, April 21st, he had a slight shiver; unfortunately he continued doing much of his work on the 22nd and 23rd. On Wednesday, the 24th, he was compelled to keep his bed, for his temperature was 105° F.; in the early hours of the 26th he had a very grave attack of palpitation and heart failure; he was then found to have pneumonic consolidation of the left lung. In spite of all that the most devoted and skilful attention could do he succumbed on April 29th, the weakness of his heart being the gravest feature of the illness.

Dr. Skerritt married in 1875 the eldest daughter of Mr. John Heelas, then living at Wokingham, now of White-knight's Park, Reading. He had one daughter, who died after a few hours' illness in 1905. He never got over this sorrow; and although he went on with his work and devoted himself with unremitting care to his wife, those most intimate with him realised that the brightness had passed from his life. The funeral took place on May 2nd, amid scenes of the most widespread sympathy and sorrow. The service was held in St. Paul's Church, Clifton, which was thronged with a sorrowing congregation, which included nearly all the medical men in Bristol and many prominent citizens, who thus testified to the respect in which Dr. Skerritt was held. The interment was at the Redland Green Cemetery, at which also a great crowd of sympathetic mourners had gathered.

Dr. Skerritt was no ordinary man. Rather slight in stature and without a particle of self-assertiveness he impressed all who came in contact with him with his force of character, and he equally attracted them by his unfailing geniality and bright humour, which made him always a welcome companion. He had great intellectual gifts; he had trained himself to be methodical, painstaking, and accurate almost to a fault. These qualities made him a skilled physician and a wise counsellor. Beyond that, however, he was a man of sterling uprightness and of unimpeachable sincerity; he was a man to be trusted. But over and above that, behind a nature reserved and shy he hid a heart of the strongest and truest affection, and so it seemed to be a necessity to him to be a friend to all who sought his aid and he ever took a keen pleasure in helping in the best way he knew all who would let him. And so it is that his death is felt in a very wide circle as a loss not only of a clever trusted physician but of a true and wise friend.

ROBERT HAMILTON RAMSAY, M.D., C.M. GLASG.

Dr. R. H. Ramsay died at his residence, Duncan House, Torquay, on May 4th, after a short illness from cerebral hæmorrhage. The deceased, who was born in Edinburgh in 1824, was the son of the late Mr. Peter Ramsay, D.L., banker, and the Hon. Susan Hamilton, daughter of Lord Belhaven and Stenton. He was educated at the Universities of Edinburgh and Glasgow and graduated as M.D. and C.M. of the latter university in 1852. At the Glasgow Royal Infirmary he held the appointment of house surgeon to Lord Lister during the period immediately preceding the introduction of antiseptic methods. In 1864 he went to Torquay and in 1865 entered into residence at Duncan House, where he spent the remainder of his life. Passionately fond of horticulture Dr. Ramsay formed at Duncan House one of the most attractive private gardens in the West of England and his fine collection of sub-tropical plants have been much admired; his fan palms from China are the only instances in this country of their ripening seeds in quantity. He had had the honour of receiving Her Majesty Queen Victoria, and the Princesses Louise, Victoria, and Maud, and amongst other distinguished personages who have visited Duncan House have been the Grand Duchess Catherine of Russia and Lord Lytton. For 40 years he held the appointment in Scotland of Purse-bearer to the Lord High Commissioner who represents the Sovereign in the general assembly of the Church of Scotland. Dr. Ramsay was honorary consulting physician to the Erith House Institution, Torquay, for ladies of limited means with diseases of the chest. He had been for 14 years president of the Torquay Gardeners Association and for 30 years was president of the Torquay Football Club. Dr. Ramsay will be much missed in Torquay, where he was one of the oldest and most esteemed of the residents, and his great generosity to the poor will long be held in remembrance.

FREDERICK WILLIAM STORRY, M.R.C.S. ENG., L.R.C.P. EDIN.

THE intelligence of the death of Mr. F. W. Storry has been received throughout Stroud and the district with feelings of the greatest sorrow. His health had been indifferent for a considerable time and in the second week of March, accompanied by Mrs. Storry, he proceeded to the Riviera, hoping that complete rest and the warm sunshine would enable him to recuperate. At first he seemed to gain in strength but the improvement was not maintained and on March 31st he passed peacefully away at the Hôtel du Louvre, Mentone, where he was staying.

Mr. Storry was the son of the late Colonel Storry of the Bank, Howden, East Yorkshire, and was born on March 13th, 1856. His professional education was obtained at the Leeds School of Medicine, and he was admitted M.R.C.S. Eng. in 1876, taking the diploma of L.R.C.P. Edin. in 1880. He was house surgeon to the Stroud General Hospital from 1879 until October, 1881, when he resigned to join in partnership the late Dr. G. R. Cubitt of Stroud. A month later he was appointed honorary surgeon to the Stroud General Hospital. In the welfare of this institution he at all times took the keenest interest and at the time of his death he was the senior surgeon. Gifted with a natural enthusiasm for surgery, he was quick to adopt the principles of the aseptic treatment, then in its infancy, and soon gained the well-deserved reputation of being a bold and successful operator. He won the confidence of his patients in a remarkable degree and became one of the busiest and most hard-working practitioners in the district. He was a past President of the Gloucestershire branch of the British Medical Association and a member of the Council at the time of his death.

A man of fine physique and possessed of a genial and hospitable temperament, he had made a wide circle of friends, by all of whom his untimely death will be long and keenly felt, and the greatest sympathy will be extended to Mrs. Storry and the son and daughter whom he leaves.

The funeral took place at the cemetery at Mentone, a most beautiful spot, and the last resting place of many English who have died away from their native land.

ROBERT HUGHES, M.D. St. And., M.R.C.S. Eng., L.S.A.

Penmaenmawr has just lost one of its most prominent inhabitants in the death of Dr. Robert Hughes, which took place on April 24th. He was well and widely known throughout North Wales. He was a son of the late Mr. Hugh Hughes, quarry proprietor, Trefriw, and was one of four brothers, three of whom were members of the medical profession. He belonged to a literary family and was first cousin of the Rev. Edward Jones, late rector of Llanfaircaereinion, editor of the Llanrwst edition of Goronwy Owen's works, and writer of the brilliant critical essay which forms an introduction to that volume.

Dr. Hughes, who was in his eighty-second year at the time of his death, received his professional education in Dublin. He took the diplomas of L.M. Dub. in 1856, M.R.C.S. Eng. in 1858, and L.S.A. in 1859; in 1862 he graduated as M.D. at the University of St. Andrews. He was appointed surgeon to the Penmaenmawr quarries nearly half a century ago but resigned the appointment when he retired from practice some ten years ago. He had in the prime of life a very extensive and important practice and attended some of the leading men of the age, such as the late Right Hon. W. E. Gladstone, and the late Archbishop Thompson, when staying at Penmaenmawr in the summer season. He was a skilful operator and the author of many literary contributions on various subjects. As a medical man he was looked upon as a leading practitioner in North Wales. It would be impossible to exaggerate the kindness of his heart in dealing with the poor in his profession, but his interest was by no means confined to his calling. He was an ardent Welshman and was possessed of an accurate knowledge of the Welsh language as well as of an extensive acquaintance with Welsh history and Welsh literature. For many years he was a member of the local board of which he filled the posts of chairman and vice-chairman and many years ago occupied the position of President of the North Wales branch of the British Medical Association. He possessed striking individuality of character and formed his views on most subjects independently of party ties and traditions. He was a strong, tender-hearted, cultured, and gifted man and his death will be long and keenly felt by his many friends. The funeral, which took place on April 27th, was a large and representative one and he was laid to rest amidst universal manifestations of sympathy and respect. A large number of beautiful floral tributes were sent from different parts of the country. On the following day the vicar (Rev. Canon Jones) in the course of his sermon made a touching reference to the deceased and paid an eloquent tribute not only to the late Dr. Hughes but to the medical profession in general.

THE ROYAL SOCIETY CONVERSAZIONE.

When a council of Britain's leading scientific men decides upon allowing a temporary scaffolding to be erected in its almost sacred meeting room in order to demonstrate an invention it may safely be concluded that there must be something highly important about that invention. This decision had the effect on Wednesday at the conversazione of the Royal Society of directing the attention of the visitors almost exclusively to one exhibit, although the occasion was one on which the exhibits in general were more than usually attractive. The topic of the evening was Mr. Louis Brennan's Mono-railway. In the inventor's own words, each vehicle on this system is provided with automatic stability mechanism which endows it with the power of maintaining its equilibrium upon a single rail either while standing still or travelling at any rate of speed. The mechanism consists of two gyroscopes (or fly-wheels the axis of which can turn in any direction) revolving in opposite directions. The "precession" or top-like motion being accelerated produces a turning couple at right angles to the rail. The principal effect of the gyroscope is that when attached to a moving body it resists change of direction and preserves absolute equilibrium. It would be difficult to enumerate the applications of this principle, but there seems to be little doubt that it will soon be practically demonstrated in regard to railways, motors, flying machines, and other methods of locomotion. Already we know how the gyroscope may be applied for preventing the rolling of ships at sea, and working models were shown in the secretary's room which clearly demonstrated this particular application of this most fascinating principle of mechanics.

Coming to exhibits which more or less relate to medicine in some of its branches we may mention the excellent skiagraphs shown by Dr. Robert Knox and Mr. G. Pearce. The examples illustrated the advantages of reduction in exposure which secures increased definition, and the outlining of the organs while the patient is not submitted to an overdose of the x rays. Close by were some very attractive specimens of pure fused silica ware made at a temperature of 2000° C. in the electric furnace. When polished it shows a beautiful pearl-like lustre and resists the action of extreme changes of temperature, while it threatens to replace platinum in chemical operations since it is unaffected by acids. Mr. W. A. Douglas Rudge's exhibit attracted considerable attention; it was devoted to proving that the action of radium and other salts on gelatine culture medium was purely chemical, a kind of cellular growth apparently forming which, after all, was due to the production of an insoluble precipitate with the sulphuric acid usually present in commercial gelatin. These experiments seem to dispose completely of the idea of "radiobes." Sir James Dewar showed that the motion of the Crookes radiometer was arrested in very high vacua, while Dr. J. T. Bottomley and Mr. F. A. King conducted some beautiful experiments with vacuum gold leaf electroscopes illustrating mechanical temperature effects in rarefied gases. On the middle bench in the library the Hon. C. A. Parsons exhibited some very fine photographs of microscopic diamonds obtained from pure iron heated in a carbon crucible in an electric furnace and rapidly cooled. On the same table Mr. H. B. Fantham exhibited microscopic preparations of *Spirochæta* (trypanosoma) *balbianii* from the crystalline style and intestine of the oyster, while Professor W. B. Bottomley's exhibit dealing with the fixation of nitrogen by leguminous and other plants proved to be very attractive. Plants were shown demonstrating the effect of artificial inoculation. In one experiment on certain soil in which inoculation was adopted the yield of beans, peas, &c., was 12 tons 5 cwt., against 7 tons 1 cwt. when inoculation was not applied.

The Right Honourable the Lord Rayleigh, O.M., D.Sc., D.C.L., the President, received the visitors. The rooms were crowded and presented a most animated scene, but the word "gyroscope," was heard most.

Medical News.

University of Durham (Faculty of Medicine).—At the Convocation held on April 27th the following degrees and diploma were conferred:—

Doctor in Medicine.—Robert Simpson Hindmarch, M.B., B.S. Durh.; Andrew Banks Raffle, M.B., B.S. Durh.; Norcliffe Roberts, M.B., B.S. Durh.; Frederick Riddle Scott, M.B., B.S. Durh.; and Alan Ayre Smith, M.B., B.S. Durh.

Doctor in Medicine for Practitioners of 15 years' standing.—Edwin Alfred Bennett, L.R.C.S.E., L.S.A.; Joseph Buck, L.R.C.P. & S.E., L.F.P.S.G.; John Martin Coates Cole, M.R.C.S., L.M., L.K.Q.C.P.I.; Charles Thomas Thornton Comber, M.R.C.S., L.R.C.P.; Alexander Cuffe, F.R.C.S.I., L.A.H.; Harry Legh de Legh, M.R.C.S., L.R.C.P.; William Charles Ellis, L.R.C.P. & S.E., L.F.P.S.G., L.S.A.; Charles Julian Horner, M.R.C.S., L.R.C.P., L.S.A.; Timoth Leahy-Lynch, L.R.C.P. & S.E., L.F.P.S.G.; Thomas McMillan, L.R.C.P. & S., L.F.P.S.G.; Edward Posnett, M.R.C.S., L.R.C.P., L.S.A.; Colamarsnacuppl Bangalore Ramarao, B.A., L.M. & S. Madras; Howard Slater, M.R.C.S., L.R.C.P., L.S.A.; Peter Campbell Smith, L.R.C.P. & S., L.F.P.S.G.; David Thomas Wylie, L.R.C.S.I., L.M.

Bachelor in Medicine (M.B.).—Harold Henry Blake, St. George's Hospital; Gilbert Iliffe Cumberlege, William Morton Emmerson, L.S.A., and Sydney Havelock, B.Sc., College of Medicine, Newcastle-upon-Tyne; Thomas Davidson Miller, M.R.C.S., L.R.C.P., St. Thomas's Hospital; David Ranken, Howard Bewlay Stephenson, L.R.C.P. & S.E., L.F.P.S.G., Norman Spedding, and Richard Woodward Swayne, College of Medicine, Newcastle-upon-Tyne; and Herbert Hoyle Whaite, L.R.C.P. & S.E., L.F.P.S.G., Birmingham University.

Bachelor in Surgery (B.S.).—Harold Henry Blake, St. George's Hospital; Gilbert Iliffe Cumberlege, William Morton Emmerson, L.S.A., and Sydney Havelock, B.Sc., College of Medicine, Newcastle-upon-Tyne; Thomas Davidson Miller, M.R.C.S., L.R.C.P., St. Thomas's Hospital; David Ranken, Howard Bewlay Stephenson, L.R.C.P. & S.E., L.F.P.S.G., Norman Spedding, and Richard Woodward Swayne, College of Medicine, Newcastle-upon-Tyne; and Herbert Hoyle Whaite, L.R.C.P. & S.E., L.F.P.S.G., Birmingham University.

Diploma in Public Health.—Ernest George Dryden Benson, L.R.C.P. & S.E., L.F.P.S G.

University of London: University College.—A series of lectures and demonstrations was commenced on Wednesday, May 8th, in the physiological department at University College, London, and will be continued on Wednesday afternoons at 5 P.M. The lecturer (Dr. W. Page May) announces his subject as the Arrangement and Functions of Certain Structures in the Central Nervous System, and the syllabus is as follows:—

Lecture 1. May 8th.—On the Peripheral Sensibilities, Spinal Ganglia, and the Commencement of the Afferent Path.

Lecture 2. May 15th.—The *Spinal Cord.* Its Various Tracts and Centres. Localisation.

Lecture 3. May 22nd.—The Medulla Oblongata.

Lecture 4. May 29th.—The Pons Varolii.

Lecture 5. June 5th.—The Cerebellum. Its Structural Arrangement, Connexions, and Functions.

Lecture 6. June 12th.—The Mid-Brain and Corpora Quadrigemina.

Lecture 7. June 19th.—The Cerebral Cortex. Motor and Sensory Areas and Functions.

Lecture 8. June 26th.—The Integrative Action of the Nervous System. Summary.

The Mercers' Company lectures on the Internal Media of the Body and their Relation to the Tissues will be given in the same department by Professor Ernest H. Starling, F.R.S., on Fridays at 5 P.M., commencing to-day, Friday, May 10th. The following points will be dealt with, according to the published schedule of the lectures:—

1. The watery content of protoplasm and the osmotic relationships of cells.
2. The internal fluid media of metazoa. Cœlomic fluid, blood, lymph.
3. The intake of fluid by intestines (and skin).
4. The supply of fluid to the tissues. Lymph and its functions.
5. The production of tissue fluid and lymph.
6. The absorption of tissue fluid and lymph.
7. The output of fluid from the body. The secretion of urine.
8. The regulation of the molecular concentration of the body fluids.
9. The regulation of the total fluid contents of the body under varying conditions, such as bleeding, transfusion, muscular exercise, heart failure, high altitudes, intoxications, &c.

These lectures are open to all students of the London medical schools and to medical men on presentation of their cards.

Longevity.—Mr. James Carne, the parish clerk of St. Columb Minor, Cornwall, celebrated the 101st anniversary of his birthday on May 3rd.—At the last meeting of the Chard (Somerset) board of guardians it was reported that a recipient of outdoor relief had just attained the age of 100 years.

Royal Institution.—A general monthly meeting of the members of the Royal Institution was held on May 6th, Sir James Crichton-Browne, treasurer and vice-president, being in the chair. Mr. J. H. Morrell, Dr. O. Oberländer, and Mr. F. L. Pattisson were elected members. It was announced that the President had nominated the following vice-presidents for the ensuing year: The Right Hon. Lord Alverstone, G.C.M.G., Sir Benjamin Baker, K.C.B., Dr. Donald W. C. Hood, C.V.O., Sir Andrew Noble, K.C.B., Mr. Alexander Siemens, the Right Hon. Sir James Stirling, Sir James Crichton-Browne (treasurer), and Sir William Crookes (honorary secretary).

The Health of the People.—Representatives from more than 30 societies interested in the question of national health were present at a meeting held at the Royal United Service Institution on May 2nd, when the Bishop of Ripon presided. In proposing

> That this meeting expresses its sympathy with the efforts now being made to make it illegal for any child under 14 to be taken into, or allowed to enter, a public-house,

the Rev. H. Russell Wakefield said that children must be protected from the ignorance of their parents, while the training and treatment of children in school should be such that when they became parents they in their turn would look after and care for their children in a proper manner. Mrs. Bramwell Booth, who seconded the motion, said that good fathers and mothers could not be made by law, but what the law laid down came at last to be acquiesced in by the masses. The motion having been carried, the chairman, in reply to a vote of thanks, said that legislation on the subject would be valuable because it would set a standard of responsibility before the people and also form an expression of the awakening of the public conscience.

Diphtheria in Tiverton.—At the meeting of the Tiverton (Devon) rural district council held on April 24th it was reported that the expenditure in connexion with the recent epidemic of diphtheria in the village of Bradninch amounted to £173. Medical fees amounted to £91 and the cost for the examination of "swabs" was £60.

Presentation to a Medical Practitioner.—On April 23rd the members of the Weston-super-Mare branch of the St. John Ambulance Brigade presented Mr. Arthur James Cary, L.R.C.S., L.R.C.P. Irel., with a gold-mounted fountain pen in appreciation of his services as honorary lecturer.

An Electric Motor Ambulance Service.—On Monday next, May 13th, Alderman Sir Alfred Newton, chairman of the Police Committee of the Corporation of London, will open an electric motor ambulance service—a circumstance which is of considerable interest to the readers of The Lancet. The ceremony will take place at 3 P.M., on ground belonging and near to St. Bartholomew's Hospital, the entrance being in King Edward-street, Newgate-street.

Hospitals and the Rates.—At the annual meeting of the governors of the Alexandra Hospital for Children with Hip Disease, Queen-square, Bloomsbury, London, W.C., held on May 6th, under the presidency of the Duchess of Albany, the Mayor of Holborn, Mr. W. D. Rawlins, K.C., referred to the question of hospitals and the rates. He fully approved of the principle of exempting hospitals from the payment of rates. The matter rested with Parliament, but any measure brought forward would have the full sympathy of his council.

Medico-Psychological Association.—At a meeting of this association to be held at 11, Chandos-street, W., on May 16th, at 3 P.M., the treasurer will make a short statement on the Workmen's Compensation Act (1906) and move the appointment of a committee to consider the rates proposed to be charged by insurance offices in respect of asylum officers, to collect evidence as to the special risks attaching to service in asylums, and to take such action in making representations as it may think fit. After the meeting members will dine together at the Café Monico, Piccadilly Circus, at 7 P.M., evening dress being optional. Tickets (exclusive of wine), 7*s.* 6*d.*, can be obtained by applying to Dr. C. Hubert Bond, honorary secretary, 11, Chandos-street, W.

Tottenham Hospital.—The opening of the new wards and operating theatre of Tottenham Hospital was performed on May 7th by the Prince of Wales who was accompanied by the Princess of Wales. The Prince also consented, at the request of the governors, to allow the name of the hospital to be changed to "The Prince of Wales's General Hospital, Tottenham." The hospital was established in 1869 and provided 73 beds; at the present time it accommodates 120 beds. The extensions just completed consist of a new wing of three floors, with an operating theatre and adjuncts above. The architects, Messrs. Rowland Plumbe and Harvey, received hearty congratulations on their work, considerable attention being attracted by the fire-resisting materials of which the buildings have been constructed. The rounded angles between the floors and the walls are formed in Diespeker's mosaic and the floors are finished with cement and covered with linoleum. The sanitary spurs to the wards are cut off by means of ventilating corridors which are treated as bridges with ventilating openings over. The wards are heated by means of Teale's stoves and in some cases have radiators intended to be used in extremely cold weather. The operating theatre, the surgeon's room, and the anæsthetising room have marble mosaic floors continued up with rounded skirting around the walls for a height of about 5 feet as a dado. The roof of the theatre is so constructed that the ridge carries the weight, thereby avoiding the use of tie rods that would collect dust. The fittings in the theatre stand in nearly every case quite clear of the walls. The fittings over the sinks are like those at the London Hospital and give hot or cold or tepid water at will. The theatre is so arranged that the walls and floors can be washed down with a hose.

THE King has sent a present of linen to the Chelsea Hospital for Women.

WESTERN COUNTIES IDIOT ASYLUM, STARCROSS.—The annual report of this institution for the year 1906 shows that the number of patients at the end of the year was 272. During the year 58 cases were admitted, 58 were discharged, and two died. Among the patients there were 15 private cases, the remainder being paupers. The average weekly cost was 11*s.* 9*d.* The Commissioners in Lunacy in their report state "that the success attained by the patients reflects great credit on those who are responsible for their training."

FOLKESTONE BOROUGH COUNCIL AND THE NATIONAL REGISTRATION OF PLUMBERS.—At the last meeting of the Folkestone borough council a letter was read from the Worshipful Company of Plumbers requesting the corporation to appoint a representative to take part in a proposed deputation to the Local Government Board to urge the Government to pass an Act for securing the competency, certification, and registration of plumbers under proper statutory authority. It was resolved:—

> That this council approves of the passing of such a Bill and that Alderman Penfold be appointed as the representative of this corporation to take part in the proposed deputation.

THE CHEMISTS' EXHIBITION.—This annual exhibition, which was inaugurated 12 years ago, continues to secure the support of the principal representatives of the drug and allied trades. It enjoys, in fact, a bigger patronage, both in regard to exhibitors and visitors, every succeeding year and the organisers may be congratulated on having set on foot a scheme which has met with such appreciation and success. As was the case last year, the exhibition was held at the Royal Horticultural Hall, Vincent-square, Westminster, and on Monday last Mr. Idris, M.P., declared the exhibition open after making a few suitable remarks in which he pointed out that the scheme was supported, not only by druggists and pharmacists in Great Britain, but by many from the colonies also. On the present occasion there were nearly 100 exhibitors, the result being that there was a good deal that was interesting and instructive to see. Needless to say, the medical profession was well represented amongst the visitors who found presented for inspection many objects of interest connected with medicine and pharmacy. Advances in methods of administration formed a feature of the exhibits and some of the most imposing stalls were reserved for a demonstration of organo-therapeutic products. The exhibition closes to-day (Friday).

WEST AFRICAN MEDICAL SERVICE.—Mr. W. H. Langley, C.M.G., deputy principal medical officer in Northern Nigeria, has been selected for appointment as principal medical officer of the Gold Coast, *vice* Dr. W. R. Henderson, C.M.G., retired. Dr. J. P. Fagan, senior medical officer in Southern Nigeria, has been selected for promotion to deputy principal medical officer in Northern Nigeria. Mr. A. H. Hanley, C.M.G., principal medical officer in Sierra Leone, has retired on pension from Feb. 16th, 1907. Mr. P. M. Forde, senior medical officer in the Gambia, is promoted to be principal medical officer in Sierra Leone. Mr. T. Hood, senior medical officer in Sierra Leone, is transferred to the Gambia. Dr. R. H. Kennan, medical officer in the Gold Coast, is promoted to be senior medical officer in Sierra Leone. Dr. C. R. Chichester, senior medical officer in Southern Nigeria, has been selected for transfer to Northern Nigeria. Dr. St. G. Gray, medical officer in Sierra Leone, has been selected for promotion to senior medical officer in Southern Nigeria on the transfer of Dr. C. R. Chichester. Mr. A. T. Latchmore, medical officer in Sierra Leone, is retired from the service on the ground of ill-health, receiving a gratuity. Dr A. N. de Gruchey, medical officer in Southern Nigeria, and Dr. J. Tichborne, senior medical officer in Northern Nigeria, are also retired on the ground of ill-health. The following gentlemen have been appointed to the staff, to date from April 27th:—Dr. H. O'H. H. May (Gold Coast), Dr. A. W. Atkinson (Gold Coast), Mr. W. N. Alexander (Sierra Leone), Mr. J. M. O'Brien (Gold Coast), Dr. G. E. H. Le Fanu (Gold Coast), Mr. R. W. Orpen (Sierra Leone), Dr. J. M. W. Pollard (Northern Nigeria), Dr. C. W. McLeay (Northern Nigeria), and Mr. T. M. R. Leonard (Southern Nigeria). The death is reported of Dr. R. E. Little, on March 11th, and of Dr. J. A. Gordon White, on March 16th, both medical officers in Southern Nigeria.

THE HOMES FOR INEBRIATES ASSOCIATION.—The twenty-third annual report of the Dalrymple Home at Rickmansworth, where the work of the Homes for Inebriates Association is carried out under the superintendence of Mr. F. S. D. Hogg, should be an encouraging one for the supporters of the association. Mr. Hogg, while pointing out that he must necessarily lose touch with many of his patients after their discharge, says that during a period of eight years out of 300 patients about 62 per cent. are doing well, 17 per cent. have improved, and 20 per cent. show no improvement. Mr Hogg, commenting upon the causes of inebriety, makes the interesting remark that the diathesis which is connected with a tendency to indulge in alcohol is more frequently transmitted through the mother, while he also finds that about 60 per cent. of the admissions to the Dalrymple Home state that the origin of their trouble was "sociability and the influence of occupation or of no occupation." Donations and subscriptions may be sent to the chairman, Rev. Canon Duckworth, 6, Little Cloisters, Westminster, London, S.W., or to the secretary, Court Chambers, 173, Marylebone-road, London, W. The accounts show a net profit on the year's working, 1906–07, of £333.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Society of Apothecaries of London Bill.

THE Society of Apothecaries of London Bill has passed its second reading in the House of Commons. It has already passed through all its stages in the House of Lords.

Royal Army Medical Corps (Volunteers).

In the annual return on the volunteer corps of Great Britain it is stated that the establishment of the Royal Army Medical Corps (Volunteers) was 3959 on Nov. 1st, 1906 The strength of the corps at the same date was 3649 of all ranks and this total is made up of 125 officers and 3432 non-commissioned officers and men along with 92 non-efficients.

The Royal Sanitary Institute.

The Royal Sanitary Institute has petitioned the House of Commons in favour of the Butter and Margarine Bill, the Infant Life Protection Bill, the Public Health Bill, and the Public Health (Regulations as to Food) Bill.

HOUSE OF COMMONS.

WEDNESDAY, MAY 1ST.

Emigrants and Vaccination.

MR. BOWLES asked the President of the Board of Trade whether he was aware that, in a circular issued by the Emigrants Information Office, intending emigrants to Canada were informed that if they travelled to Canada as steerage passengers they would be required, on arrival, either to produce a vaccination certificate or to submit to vaccination or to compulsory detention for observation in a quarantine station, while if they travelled otherwise than by steerage no such requirements would be made; and whether this was a correct statement of the Canadian regulations on the subject.—Mr CHURCHILL (who replied) said: The statement in question is substantially correct, though the words "Passengers other than steerage are not examined" might be qualified by adding the words "as a rule."

The Royal Commission on Vivisection.

Sir PHILIP MAGNUS asked the Secretary of State for the Home Department whether he could state when the Royal Commission on Experiments on Living Animals for the purposes of Research was likely to report.—Mr GLADSTONE answered: The inquiry is not sufficiently advanced to enable an answer to be given to this question.

The Chief Medical Officer of the Post Office.

Mr. HUNT asked the Postmaster-General whether he would explain why the salary of the chief medical officer of the Post Office had been raised from a maximum of £1000 per annum, with an allowance of £100 per annum, to a salary of £1200 per annum, seeing that before the Select Committee on Post Office Wages the chief medical officer admitted that he received salaries from two other institutions for medical attendance.—Mr. SYDNEY BUXTON furnished the following written reply. The salary of the chief medical officer has been raised because it was considered that as it formerly stood it did not afford adequate remuneration for the duties of the post. A proposal for this increase was first made to the Treasury in 1903. It was renewed and agreed to in February, 1906. I understand that when the chief medical officer was appointed to his present post he received permission to continue to hold the two appointments referred to, which do not interfere with the performance of his official duties

Public Health in Egypt.

Dr. RUTHERFORD had several questions on the notice paper relating to such matters as the stagnant residue in the bed of the Ismailia

Canal and the drainage and sewage in the villages and towns of Egypt.—Sir Edward Grey said: The questions put by the honourable Member relate to questions of Egyptian internal administration. And while I have every desire to encourage sanitary reform I must point out that this is one of the matters which receive constant attention from the Egyptian Government and that the direct interference of His Majesty's Government in matters of administrative detail is both impracticable and undesirable. As the honourable Member is no doubt aware, the progress of social reform in every country must be gradual and particular measures must depend upon the resources of the State.

Medical Officers in County Kerry.

In answer to Mr. Thomas O'Donnell, Mr. Birrell wrote: The salaries paid to medical officers in the unions of the county Kerry for the years ended March, 1897, and March, 1906, are as follows:—

	Year 1897.	Year 1906.
Cahirciveen	£440	£514
Dingle	640	552
Kenmare	440	440
Killarney	703	730
Listowel	600	722
Tralee	755	785

One-half of the amounts in the first column was recouped from the Parliamentary grant. Of the sums of £730 and £785 given in the second column, one-half was in each case recouped from the Local Taxation Account and in the remaining cases the amount recouped was a little less than one-half, owing to the limitation imposed by Section 6 (1) of the Local Government (Ireland) Act, 1902. In the year ended March, 1906, the following additional payments were made for remuneration of substitutes for medical officers who were absent on vacation, and recoupment of one-half of these amounts was allowed under Section 5 (1) of the Act of 1902:—

	£	s.	d.
Cahirciveen	42	0	0
Dingle	8	8	0
Kenmare	50	8	0
Killarney	29	0	0
Listowel	134	8	0
Tralee	100	16	0

The balance remaining in all the cases referred to above was defrayed out of the rates. It may be added that no portion of the agricultural grant is directly payable to relieve any specific union charge but is applied in aid of the rates on agricultural land generally.

The Maintenance of Lunatics.

Mr. William Pearce asked the President of the Local Government Board whether he would introduce legislation extending the grant of 4s. weekly now made under the Local Government Act, 1888, in respect of each lunatic maintained in a lunatic asylum, to imbeciles and lunatics certified for treatment in workhouses.—Mr. John Burns answered: Some extension of the grant in the direction desired was recommended by the Royal Commission on Local Taxation, subject to certain conditions. The matter will receive consideration when the question of local taxation is dealt with by the Government, but I could not promise to introduce legislation with regard to it at the present time.

Medical Supplies for Irish Guardians.

In the course of the debate in Committee of Supply on the Vote for the Irish Local Government Board,

Mr. Boland called attention to the contracts which Irish boards of guardians and other authorities made for supplies, including the supply of medicines for workhouses. Some of these boards had tried to encourage Irish industries by accepting tenders for supplies which were not always the lowest. He contended that it should not be in the power of the Local Government Board auditor to upset the tender although it was not the lowest sent in.

Mr. Birrell, in the course of his reply, said that with regard to medical supplies it had to be remembered that under Acts of Parliament half the cost of the drugs that were supplied to workhouses by boards of guardians in Ireland was repaid out of Imperial funds. Therefore Parliament had an interest in seeing that extravagant prices were not paid for drugs and medical supplies. Because boards of guardians got half the cost back there was not the same check that the ratepayers would get value for their money. It had been brought to the notice of the Local Government Board that boards of guardians preferred to buy the drugs from Irish firms, forgetting the fact that drugs were sent from every part of the world. The firms in Ireland who supplied them were only middlemen. In the case of drugs and medical supplies therefore it was necessary that the Local Government Board for Ireland should take a more strict view than in the case of other supplies. He did not think that the Local Government Board should relax its hold over boards of guardians. They did require to be looked after because of the fact that, although they were acting in a spirit of friendliness, acts of irregularity had not only been alleged but had been proved against them. He did not say that these were cases of dishonesty, but they were cases of favouritism, which cast a burden on the ratepayers. That ought not to be the case and whoever had control of the Irish Local Government Board would be playing an unpatriotic part if they did not maintain a sharp control over boards of guardians in all parts of the country. If this was done he was sure that in a few years a proper spirit would be developed in these bodies.

Mr. Hugh T. Barrie did not think that there was any more important contract accepted by boards of guardians than the contract for medical supplies. It was extremely important that the drugs should come from really responsible firms. However, he believed that firms in Belfast would certainly compete with any wholesale drug firms, either in Liverpool or in London. He thought that the practice in England had been to accept the lowest tender, because there was the safeguard that the medical officer would see that the guardians received what they had contracted to get. He thought that the Chief Secretary to the Lord Lieutenant had taken up a proper attitude in this important matter.

The subject then dropped and the vote was ultimately agreed to.

Monday, May 6th.

The Board of Education and a Medical Department.

Mr. Wedgwood asked the President of the Board of Education on what expert opinion Clause 10 of the Education (Administrative Provisions) Bill was drafted; and whether this expert opinion reported as well upon the necessity of establishing a permanent medical department at the Board of Education, and, if so, what their view of such a medical department was.—Mr. McKenna answered: Clause 10 of the Administrative Provisions Bill follows precisely the wording of the similar clause of last year's Bill as amended in Parliament. A considerable volume of expert opinion bearing on the subject will be found in the reports of the Inter-Departmental Committees on Physical Deterioration and on the medical inspection and feeding of school children which have been already published. I do not think the matters referred to in the last paragraph can be adequately dealt with by means of question and answer. There will be an opportunity for discussing them in committee on the Bill.

Tuesday, May 7th.

Declarations under the Vaccination Bill.

Mr. Dundas White asked the President of the Local Government Board whether it was intended that any, and, if so, what, fees shall be chargeable by commissioners of oaths and other officers in respect of declarations made under the recently introduced measure dealing with vaccination; and whether he would consider the desirability of inserting in the Bill an express provision with regard to this.—Mr. John Burns replied: The provisions of the existing law with regard to fees in respect of the statutory declarations will apply to declarations for the purposes of the Bill. Where a statutory declaration is made before a commissioner for oaths the fee is 1s. 6d. As regards fees payable when a declaration is made before a justice or magistrate the charge in the metropolitan police-courts is 1s., while elsewhere it depends on the table of justices' clerk's fees in force whether any, and, if so, what, fee is payable. In the model table of fees issued by the Secretary of State the suggested fee for a declaration is 1s. I may add that a fee of 1s. 6d. or 2s. is payable now in most cases where a certificate of conscientious objection is obtained under Section 2 of the Vaccination Act, 1898.

Wednesday, May 8th.

Marriage and the Transmission of Disease.

Captain Faber asked the Prime Minister whether his attention had been called to the fact that several State legislatures in America had passed Bills to prevent marriages taking place unless both parties were, in the opinion of a qualified physician, free from disease transmissible to their children; and whether he would consider the desirability of introducing a similar Bill here.—Sir Henry Campbell Bannerman answered: I do not propose to undertake legislation on this subject this session.

BOOKS, ETC., RECEIVED.

Baillière, Tindall, and Cox, 8, Henrietta-street, Covent Garden, London, W.C.

Treatment by Hypnotism and Suggestion, or Psycho-Therapeutics. By C. Lloyd Tuckey, M.D. Aberd., late Visiting Physician to Margaret-street Infirmary; Membre Fondateur de la Société d'Hypnologie; Honorary Member of the American Society for the Study and Cure of Inebriety; President of the Medical Society for the Study of Therapeutic Suggestion. Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.*

Devane, J. F., M.B., D.P.H., has been appointed Assistant House Surgeon at the Huddersfield Infirmary.

French, J. Gay, M.B., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Surgeon to the Ear and Throat Department, with Charge of Out-Patients, at the Great Northern Central Hospital.

Gilbert, William, M.B., Ch.B. Glasg., has been appointed Assistant House Surgeon at the Huddersfield Infirmary.

Hertz A. F., M.B., B.S. Oxon., has been appointed Assistant Physician to Guy's Hospital.

Jordan, Alfred C., M.D., B.C. Cantab., has been appointed Medical Radiographer to Guy's Hospital.

Murray, H. Leith, M.D. Aberd., has been appointed Joint Pathologist to the David Lewis Northern Hospital, Liverpool.

Reith, W. R., M.D., M.S. Aberd., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Erdington District of the county of Warwick.

Shaw, Lauriston E., M.D. Lond., F.R.C.P. Lond., has been appointed Physician to Guy's Hospital.

Symes, J. O., M.D. Lond., D.P.H., M.R.C.S., L.R.C.P. Lond., has been appointed Consulting Physician to the Cossham Memorial Hospital, Kingswood, Bristol.

Taylor, Frederick, M.D. Lond., F.R.C.P. Lond., has been appointed Consulting Physician to Guy's Hospital.

Whitehouse, A. Landon, M.R.C.S., L.R.C.P., L.D.S. Eng., has been appointed Honorary Curator of the Museum, Royal Dental Hospital of London.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Army Medical Service.—Examination for Thirty Commissions in the Royal Army Medical Corps.

Bath, Bailbrook House.—Assistant Medical Officer. Salary £140 per annum, with board, lodging, laundry, and attendance.

Belgrave Hospital for Children, Clapham-road, S.W.—Senior and *Junior Resident Medical Officers for six months.* Honorarium at the rate of £20 and £10 a year respectively, with board and lodging.

Brentford Union *Workhouse and Schools*, Isleworth, W.—Second Assistant Medical Officer, unmarried. Salary £125 per annum, with lunch and tea daily and dinner when on late duty.

Brighton, Sussex County Hospital.—House Physician, unmarried. Salary £80 per annum, with board, residence, and washing.

Bury St Edmunds, *West Suffolk General Hospital.*—House Surgeon, unmarried. Salary £100 per annum, with board and lodging.

Cancer Hospital, Fulham-road, London, S.W.—House Surgeon.

Canterbury City Asylum.—Assistant Medical Officer, unmarried. Salary £140 per annum, with board, apartments, and laundry.

Carmarthen, Joint Counties Lunatic Asylum.—Medical Superintendent. Salary £450 per annum, with house, fire, light, and washing. Also Assistant Medical Officer. Salary £200 per annum, with board, lodging, washing, and attendance.

Cheltenham General Hospital.—House Physician, also Surgeon-in-Charge of Branch Dispensary, both unmarried. Salary of *former* £65 and of latter £90 per annum, with board and lodging.

Chesterfield and North Derbyshire Hospital and Dispensary.—*Junior House Surgeon.* Salary £80 a year, with board, apartments, and laundress.

Cuckfield Union.—Medical *Officers* for Districts *No.* 2, *No.* 6, and No. 7. Salaries £50, £40, and £100 per annum respectively and extra medical fees.

Douglas, Isle of Man, Noble's Isle of Man Hospital and Dispensary.—*Resident House Surgeon*, unmarried. Salary £90 a year, with board and washing.

Dumfries and Galloway Royal *Infirmary.*—House Surgeon and Assistant House Surgeon. Salaries £80 and £25 respectively, with board and lodging.

Eastern Dispensary, Leman-street, Whitechapel, E.—Surgeon. Salary £50 per annum.

Essex and Colchester General Hospital.—House Surgeon. Salary £80 per annum, with board, washing, and residence.

Evelina Hospital for Sick Children, Southwark Bridge road, S.E.—House Physician, *House Surgeon*, and Assistant House Surgeon. Salary of two former £80 and of latter £70 per annum, with board, residence, and washing.

Exeter, Royal Devon and Exeter Hospital.—Assistant House Surgeon, unmarried. Salary £60 per annum, *with board, lodging*, and washing.

Gloucester, General Infirmary and *Gloucestershire* Eye Institution.—Assistant House Surgeon for six months. Salary at rate of £30 per annum, with board, residence, and washing.

Gordon Hospital, Vauxhall Bridge-road, S.W.—Resident House Surgeon.

Guildford, Royal Surrey County Hospital.—Assistant House Surgeon. Salary £50 per annum, with board, *residence*, and *laundry*.

Guy's Hospital Dental School.—Travelling Scholarship. Value *£100.*

Hospital for Sick Children, Great Ormond-street, *London*, W.C.—*House Surgeon*, unmarried, for six months. Salary £20, with board and residence.

Kensington General Hospital, Earl's Court, London, S.W.—Assistant Surgeon.

Kensington Workhouse and Infirmary.—Second Assistant Reside Medical Officer. Salary £100 per annum, with apartments, board and washing.

Lambeth Parish Infirmary, Brook-street, Kennington-road, S.E.—Clinical Assistant for six months. Salary at rate of £100 p annum, with residential allowances.

Liverpool Stanley *Hospital.*—*Junior House Surgeon.* Salary £ per annum, with board, residence, and washing.

London (Royal Free Hospital) School of Medicine fo Women, 8, Hunter-street, W.C.—*Second Demonstrator of Anatom* (female).

Maidstone, West Kent *General Hospital.*—Assistant Hou Surgeon and Anæsthetist, unmarried. Salary £60, with board lodging, and washing.

Manchester and Salford Hospital for Skin Diseases.—Hou *Surgeon. Salary £75 per annum*, with board and residence.

Metropolitan Hospital, Kingsland-road, N.E.—Surgeon. Als *Assistant Surgeon.*

Middlesex Hospital.—Medical Officer and Registrar to the Cance Department. Salary £100 per annum, with board and lodging.

Miller Hospital, Greenwich road, S.E.—Junior House Surgeon Salary at rate of £80 per annum, with board, attendance, an washing.

Newport and Monmouthshire Hospital.—Junior Resident Medic Officer. Salary £70 per annum, with board, residence, an laundry.

Northampton, Berry Wood Asylum.—Junior Assistant Medic Officer, unmarried. Salary £150, increasing to £200, with board, lodging, washing, and attendance.

North-Eastern Hospital for Children, Hackney-road, Bethnal Green, E.—Medical Officer in Charge of Electrical Department Salary £50 per annum.

Paddington Infirmary and Workhouse.—First Assistant to the Medical Superintendent of the Infirmary and Assistant Medical *Officer of the* Workhouse. *Salary £120 per annum, rising to £150* per annum, with board, lodging, and washing.

Royal College of Surgeons of England.—Hunterian Professor, Arris and Gale Lecturer, and Erasmus Wilson Lecturer; also *Jacksonian* and *Cartwright Prizes.*

Royal Ear Hospital, Dean street, Soho, W.—House Surgeon for six months. *Salary at rate of £40* per annum.

Royal Eye Hospital, Southwark, S.E.—House Surgeon. Salary *£52* 10s. per annum, with board and residence.

Royal Free Hospital, Gray's Inn road, W.C.—Assistant to the Clinical Pathologist and Assistant Anæsthetists (females).

Royal Waterloo Hospital for Children and Women, S.E.—Junior Resident Medical Officer. Salary at rate of £40 per annum, with board and washing.

St. Bartholomew's Hospital.—Assistant Physician-Accoucheur, Assistant Surgeon, and Assistant Aural Surgeon.

St. Mark's Hospital for Fistula and other Diseases of the Rectum, City-road, E.C.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

St. Mary's Hospital, Paddington, W.—Physician in Charge of Out-Patients.

St. Thomas's Hospital.—Assistant Physician.

Scarborough Hospital and Dispensary.—Junior House Surgeon. Salary £80 per annum, with board, residence, and laundry.

Swansea General and Eye Hospital.—House Surgeon. Salary £75 per annum.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—House *Physician for six months. Honorarium* of £30, with board and lodging.

Warwick *County Lunatic* Asylum, Hatton, Warwick.—Junior Assistant Medical Officer. Salary £130, with board, lodging, and washing.

West Bromwich District Hospital.—Resident Assistant House Surgeon, unmarried. Salary £75 per annum, *with board*, residence, and washing.

West-End Hospital for *Diseases of the* Nervous System, &c., 73, Welbeck-street, London, W.—Resident House Physician and Medical Registrar. *Salary at rate of 50 guineas per annum*, with board, washing, and attendance.

Wigan, Royal Albert Edward Infirmary.—*Junior House Surgeon.* Salary £100, with apartments, washing, and rations.

Worcester General *Infirmary.—House Physician. Salary £80* per annum, with board and residence.

Births, Marriages, and Deaths.

BIRTHS.

Barnicot.—On May 4th, at 40, Queen-street, Hitchin, Herts, the wife of J. Barnicot, M.D., of a son.

Dunnett.—On May 6th, at Ascott-avenue, Ealing, Agnes Dunnett, M.B. Lond., wife of Lionel Francis Dunnett, of a daughter.

Heggs.—On April 30th, at *Toronto House*, West Bromwich, the wife of Raymond Mitchell Heggs, L.R.C.P. Lond., M.R.C.S., of a son.

MARRIAGE.

De Voss—Kanthack.—On May 8th, at the German Church, Montpelier-place, Brompton-road, S.W., Gustav de Voss, of 5, Eichen Strasse, Gross Flottbek, Holstein, Germany, to Emilia Victoria, daughter of *Emilio* Kanthack, of Sherborne, Mortlake-road, Kew Gardens.

DEATHS.

Abbott.—On May 4th, at Killiney House, Killiney, Arthur J. Abbott, M.D. T.C.D., second son of Rev. Dr. Abbott, S.F. T.C.D., aged 41.

Macartney.—At 18, Newton-place, Glasgow, on 5th inst., Jessie Jane Logan, wife of Dr. Duncan Macartney.

MacDonald.—On May 3rd, at Stornoway, Lewis, Donald J. MacDonald, M.B., C.M., D.P.H. Aberd., J.P.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"THE ANTI-OPIUM REMEDY."

FURTHER particulars of "the anti-opium remedy" are quoted in the *Pharmaceutical Journal* from the *Journal of the Federated Malay States Museums* for December, 1906. The history of the discovery of the plant Combretum sundaicum and the reason for roasting it previously to use is as follows. A party of Chinese wood-cutters, working in the jungle near Seremban, ran out of tea and to supply its place took the leaves of a jungle climber, dried them, and made an infusion in the usual way. This substitute was not found to be successful, as it produced bowel complaint among the men. It was found, however, that the leaves on being roasted formed a fair substitute for tea and produced no ill-effects. Then for some obscure reason kengko—i.e., opium dross or the refuse opium after being smoked—was mixed with it and the men continued to drink the infusion prepared from the mixture for a week or more in place of tea. After this time it was found that all desire for opium smoking had been lost. The news of the discovery then spread with great rapidity and others were induced to try the remedy. In preparing the drug for use care is taken to separate the leaves from the stems and to roast them separately, in order to avoid undue heating of the leaves. A decoction is prepared by boiling from eight to 11 ounces of the roasted stems and leaves in four gallons of water for about three hours, and straining the liquid into a barrel. No preservative is used, so that the decoction is very subject to fermentation, and fresh supplies have to be obtained frequently. It is stated that a Chinese opium smoker consumes from 116 to 175 grains of opium daily, although in one case as much as 875 grains form the daily allowance. The opium is less potent than the B.P. extract of opium and a considerable quantity of the alkaloids present are destroyed during the process of smoking, so that only a small portion is absorbed into the system of the smoker. If a man has been in the habit of smoking 116 grains of opium per day then that quantity of opium is roasted in the same way as it would be if prepared for smoking and placed in a bottle containing 25 fluid ounces of the decoction. Then a dose of three fluid ounces is taken by the patient, after which three fluid ounces of the simple decoction of the anti-opium plant are transferred to this bottle from another bottle containing 25 fluid ounces of the liquid. This is repeated each time a dose is taken until the bottle of simple decoction is finished. The dose is taken as many times a day as the patient has been in the habit of smoking, usually three or four times, until both bottles are finished, when the patient should no longer desire to smoke opium. If he is not cured the treatment is repeated, with a smaller initial proportion of burnt opium, the amount being still further decreased if a third course should be necessary. Mr. L. Wray, I.S.O., the author of the article, states that generally three courses are required.

DIAGNOSIS IN EXCELSIS.

To the Editors of THE LANCET.

SIRS,—A patient of mine, a fine healthy man with no family history of consumption, has recently suffered from severe attacks of asthma. Previous to this he was a great athlete. Last year he consulted Sir Sydney Jones, who, after a very long and careful examination, said, "I can find nothing wrong except a slight trace of asthma on the right side." I have examined him frequently with the same result. Two months ago he had occasion to consult one of the leading registered dentists in Sydney who said, "By the appearance of the gums of one of your teeth I should say you were developing consumption." Is this Sherlock Holmes or what? I am, Sirs, yours faithfully,

April 2nd, 1907.

MEDICUS.

*** Let us hope that the patient reported his dentist's words incorrectly.—ED. L.

HOSPITAL ABUSE: A SUGGESTED REMEDY.

A CORRESPONDENT whose position as a member of one of the public services precludes him from signing his name has written to us. He says that his letter is of "a somewhat polemical nature," and we agree with him so far. We cannot endorse all that he says, but undoubtedly some of his forcible statements have a ground in fact. He considers that there are two main causes of hospital abuse—the one being the number of salaried officials of hospitals whose interest it is to make the work of a hospital appear as far-reaching as possible, and the other the fact that the medical and surgical members of hospital staffs, although by words opposed to hospital abuse, are not so in practice. His first complaint is not borne out by facts, while a more jealous eye than the public and perhaps many members of the medical profession are aware of is kept over hospital expenditure. With regard to the second matter, he points out that it is in the power of the medical staffs of hospitals to effect the necessary reforms if they presented a solid front. "If the hospital staffs of all London," he suggests, "said collectively to their governors, 'We demand that our expenditure of time, labour, and skill, which are absolutely indispensable to the working of the hospitals, and of far greater value to the hospitals than your contributions, be recognised by giving each one of us a voice in the control of the hospital, or we shall unanimously resign,' this most just demand would have to be at once conceded." He points out that the general practitioner is the greatest sufferer from hospital abuse and suggests the following remedy. "The general practitioner must combine and say effectively to the member of the hospital staff, 'I will not send you another case till the abuse at your hospital is rectified'"; and he calls upon the British Medical Association to provide the means and the organisation for carrying out this scheme.

The question of hospital abuse teems with difficulties and our correspondent's statement of the evils and suggestions for their removal are of too sweeping a nature. His letter was prompted by the recent discussion on hospital abuse at the Westminster branch of the British Medical Association. The sense of this meeting was in favour of a central hospital board, a remedy which he does not consider drastic enough. But the perfect combinations which he postulates among general practitioners and among hospital staffs have yet to be arrived at. As many have said, hospital abuse is mainly an expression of a want of organisation and of coincidence of opinion among medical men themselves. And no amount of organisation will ever get all medical men to think alike upon the subject. The letter from which we have quoted is at least an honest expression of opinion from a medical man who is neither a general practitioner nor a hospital medical officer. He is therefore presumably unbiased.

A NEGLECTED TEXT.

To the Editors of THE LANCET.

SIRS,—Heaven forbid that I should add to a controversy which suffers from being conducted upon a subject where no absolutely certain evidence can be adduced by either side and which might be made interminably long by honest opponents for just this reason. Not even the total prohibitionist is more aware of the evils caused by alcohol than is the moderate user of alcohol. And whereas the prohibitionist, looking at good work done by users of alcohol, can say that the work might have been still better if its author had been a teetotaller, it is equally open to the user of alcohol to say that many an active prohibitionist would have been a still more valuable citizen if he had taken an occasional glass of wine. Neither can be contradicted.

I am writing not to expound such obviousness but to wonder why the following text has been so neglected in all the tons of correspondence upon the alcohol question. The views of David and Timothy are constantly quoted but never this striking sentence: "And the trees said unto the vine, Come thou, and reign over us. And the vine said unto them, Should I leave my wine, *which cheereth God and man,* and go to wave to and fro over the trees?" (Judges ix. 13, revised version). I am, Sirs, yours faithfully,

M.D.

THE GOLDEN FLEECE.

A PAMPHLET bearing the above title on the cover has been sent to us with a request for a review. It bears the further title, "A New Medical Statement upon Alcohol: Analysis and Counter Statement," and comprises the opinion of the British Temperance League with regard to the recent pronouncement upon alcoholic beverages which appeared in our columns above the signatures of 16 well-known medical men. There is nothing in the pamphlet to review. We are sure that the advocates of temperance tenets are sincere in their beliefs, but once again they show that they cannot credit their opponents with an equal desire to speak the truth. The origin of the "manifesto," as the collective opinion of the writers is termed, is attributed in this pamphlet to a writer who "did political work for the 'Moderates' at the recent London County Council election, the 'Moderates' being the party which had the support of the liquor and betting interests." We are accused quite untruthfully of sending out advance copies of THE LANCET containing the pronouncement, and the intellects of the signatories are impeached on the score of their age. This sort of thing is rudeness, not analysis, and does the cause of temperance real harm.

WHITSUNTIDE ON THE CONTINENT.

RETURN tickets at reduced fares available for eight days will be issued to Brussels from May 15th to 18th and 20th, *viâ* Harwich and Antwerp. Passengers leaving London in the evening reach Brussels next morning after a night's rest on board the steamer. For visiting The Hague, Scheveningen (the Dutch Brighton), and Amsterdam for the old world cities of the Zuyder Zee, and the International Exhibition at Mannheim, special facilities are offered *viâ* the Great Eastern Railway Company's British Royal Mail Harwich-Hook of Holland route. A corridor train with vestibuled carriages, dining and breakfast cars, is run on the Hook of Holland service between London and Harwich. From the Hook of Holland through carriages and restaurant cars are run in the North and South German express trains to Cologne, Basle, and Berlin, reaching Cologne at noon, Basle and Berlin in the evening. For the convenience of passengers tickets dated in advance can be obtained at the Liverpool-street Station Continental Enquiry and Booking Offices. The Danish Royal Mail steamers of the Forenede Line of Copenhagen will leave Harwich for Esbjerg (on the west coast of Denmark) on May 15th and 18th, returning on May 21st and 22nd. The General Steam Navigation Company's steamers will leave Harwich on May 15th and 18th for Hamburg, returning on May 19th and 22nd.

HOW INFECTION IS SPREAD.

THE risks to which the community is liable from the negligence of persons suffering from infectious diseases were illustrated at Todmorden recently, where the father of a lad suffering from scarlet fever has been fined for his negligence. The proceedings were taken at the instigation of the medical officer of health who had been informed by neighbours of the lad that he had been associating with the general public. The lad himself confessed that he had been to a football match and mixed with other boys. An epidemic of scarlet fever has lately prevailed in the Cornholme part of Todmorden and since the police-court proceedings 24 cases have been notified.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—I should be glad if any of your readers could tell me of a home (private or otherwise) where an old lady suffering from aneurysm of the aorta and practically bed-ridden could be taken care of. She is prepared to pay £1 a week. Thanking you in anticipation,

I am, Sirs, yours faithfully,
J. H. YOLLAND.

53, Bromley-common, Kent, May 4th, 1907.

CYDER.

IN an analytical notice in THE LANCET of April 27th, p. 1170, of Messrs. William Gaymer's Norfolk cyder we omitted to add that the samples were found to be entirely free from objectionable preservatives. Considering how commonly cyder is preserved with salicylic acid we print this addendum with pleasure.

A NEW FORM OF DEEP-SOLED BOOT.

To the Editors of THE LANCET.

SIRS,—I should like to call attention to an invention which appears to me to be of some importance. In cases of hip disease in which there has been shortening and a boot with a deep sole has to be worn the resulting limp appears to be largely increased by the shortening of the step on the diseased side. This is produced by the comparative immobility of the ankle on the thick sole which prevents the natural bend as the body comes forward over the supporting foot. A remedy for this defect is provided by a surgical boot invented by Mr. Fageant, bootmaker, of 48, Richmond-road, Kingston-on-Thames. The foot of this boot is moveable on the sole at the junction of the anterior and middle thirds and the movement is restricted to an up-and-down one by a guide which at its greatest flexion remains over the sides of the heel. The result of the use of the boot is a considerable diminution of the limp, practically in some cases abolishing it, and the patient walks longer distances with no greater fatigue. The cost is about the same as that of other surgical boots and I feel sure that many people whose only sign of past ill-health is a limp will welcome the invention.

I am, Sirs, yours faithfully,
ROGER N. GOODMAN.

Kingston-hill, Kingston-on-Thames, April 24th, 1907.

*** We have examined the boot to which Mr. Goodman refers and agree with him that the idea is a good one.—ED. L.

During the week marked copies of the following newspapers have been received:—*Yorkshire Evening Post, Standard, Daily News, Daily Chronicle, Belfast News, Tribune, Hull Eastern Morning News, Hampstead Express, South London Press, Morning Post, Preston Guardian, Durham Chronicle, Daily Express, Glasgow Herald, Scotsman, Wimbledon Gazette, Broad Arrow, Army and Navy Gazette, Literary Digest (New York), &c.*

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (3 P.M.), St. Mark's (2.30 P.M.).

TUESDAY (14th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (2 P.M., Ophthalmic, 2.15 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (15th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.).

THURSDAY (16th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.). Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (2.30 P.M.), Tottenham (Gynæcological, 2.30 P.M.).

FRIDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (18th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (13th).—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8 P.M.: General Meeting. Election of Officers and Council, &c. 8.30 P.M.: Papers:—Dr. H. Mackenzie: Mobility of the Kidneys.—Dr. W. Broadbent: Some Heart Affections with Murmurs.

TUESDAY (14th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M.: Mr. E. M. Corner: Fractures of the Odontoid Process of the Axis (epidiascope demonstration).

WEDNESDAY (15th).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—8 P.M.: Exhibition of Pond Life. Papers:—Prof. A. W. Porter and Mr. P. F. Everitt: Diffraction Rings due to a Circular Aperture.—Mr. E. M. Nelson: An Improved Vertical Illuminator.

SOCIETY OF ARTS (John-street, Adelphi, W.C.).—8 P.M.: Dr. H. W. G. Macleod: Trypanosomiasis or Sleeping Sickness.

THURSDAY (16th).—MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND (11, Chandos-street, Cavendish-square, W.)—3 P.M.: Papers:—Dr. W. F. Robertson and Dr. G. D. McRae: Further Bacteriological and Experimental Investigations into the Pathology of General Paralysis.—Dr. H. Devine: A Case of Katatonia in a Congenital Deaf-Mute.

FRIDAY (17th).—SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11, Chandos-street, Cavendish-square, W.).—5 P.M.: Wightman Lecture:—Dr. F. Taylor: Pneumonia in Children.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (13th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—12 noon: Pathological Demonstration:—Dr. Low. 2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations. 5 P.M.: Lecture:—Major L. Rogers, I.M.S.: The Clinical Diagnosis of Fevers in the Tropics (illustrated by lantern slides).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Dr. A. Whitfield: Clinique. (Skin.) 5.15 P.M.: Lecture.

North-East London Post-Graduate College (Tottenham Hospital, N.).—Cliniques:—9.30 A.M.: Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Medical Out-patient (Dr. Whipham), Throat, Nose, and Ear (Mr. Carson); X Ray (Dr. Pirie).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 P.M.: Sir Dyce Duckworth: Medicine. 2.30 P.M.: Operations. 3.15 P.M.: Mr. W. Turner: Surgery. 4 P.M.: Dr. StClair Thomson: Diseases of the Throat, Nose, and Ear. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 12 noon: Ear and Throat.

TUESDAY (14th).—Post-Graduate College (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynæcological Operations. 2 P.M.: Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin. 5 P.M.: Clinical Lecture:—Mr. Paget.

Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 P.M.: Dr. S. Cautley: Clinique. (Medical.) 5.15 P.M.: Lecture:—Dr. W. S. A. Griffith: The Arrest of Uterine Hæmorrhage under Various Conditions.

North-East London Post-Graduate College (Tottenham Hospital, N.).—Cliniques:—10.30 A.M.: Medical Out-patient (Dr. Auld). 2.30 P.M.: Gynæcological Out-patient (Dr. Giles), Surgical Out-patient (Mr. Edmunds). Surgical Operations (Mr. Carson). 3.30 P.M.: Demonstration of Cases at Colney Hatch Asylum (Dr. H. Corner).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 P.M.: Dr. R. T. Hewlett: Medicine. 2.30 P.M.: Operations. 3.15 P.M.: Mr. Carless: Surgery. 4 P.M.: Mr. M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 12 noon: Skin. Special *Lecture*:—Mr. Carless.

Central London Throat and Ear Hospital (Gray's Inn-road, W.C.).—3.45 P.M.: Demonstration:—Mr. Stuart-Low: Middle Ear and Labyrinth.

National Hospital for the Paralysed and Epileptic (Queen-square, Bloomsbury, W.C.).—3.30 P.M.: Clinical Lecture:—Dr. Beevor: Muscular Atrophy.

WEDNESDAY (15th).—Post-Graduate College (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 P.M.: Medical and Surgical Clinics. X Rays. 2.30 P.M.: Operations. 5 P.M.: Lecture:—Mr. Pardoe: Hæmaturia.

Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 P.M.: Mr. M. Collier: Clinique. (Surgical.) 5.15 P.M.: Lecture:—Mr. B. Harman: Injuries to the Superficies of the Eye.

North-East London Post-Graduate College (Tottenham Hospital, N.).—Cliniques:—2.30 P.M.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 P.M.: Dr. F. Taylor: Medicine. 2.30 P.M.: Operations. 3.30 P.M.: Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 11 A.M.: Eye.

THURSDAY (16th).—Post-Graduate College (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations. 5 P.M.: Lecture:—Mr. Keetley: Cases of Interest in the Wards.

Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 P.M.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 P.M.: Lecture:—Mr. M. Yearsley: Syphilis in the Ear.

North-East London Post-Graduate College (Tottenham Hospital, N.).—2.30 P.M.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 P.M.: Medical In-patient (Dr. Chappel). 4.30 P.M.: Special Demonstration of Surgical Cases (Mr. W. Edmunds).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. G. Rankin: Medicine. 3.15 P.M.: Sir W. Bennett: Surgery. 4 P.M.: Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 12 noon, Ear and Throat.

Charing Cross Hospital.—4 P.M.: Dr. Eden: Demonstration (Gynæcological). (*Post-Graduate Course.*)

Hospital for Sick Children (Gt. Ormond-street, W.C.).—4 P.M.: Lecture:—Mr. G. E. Waugh: Hip Disease in Children.

FRIDAY (17th).—Post-Graduate College (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynæcological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. X Rays. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin. 5 P.M.: Lecture:—Dr. S. Taylor: Pneumonia.

Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 P.M.: Mr. W. Stuart-Low: Clinique. (Ear.)

North-East London Post-Graduate College (Tottenham Hospital, N.).—9.30 A.M.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 P.M.: Medical In-patient (Dr. Leslie).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 P.M.: Dr. R. Bradford: Medicine. 2.30 P.M.: Operations. 3.15 P.M.: Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 12 noon: Skin. Special Lecture:—Dr. R. Bradford: Jaundice.

National Hospital for the Paralysed and Epileptic (Queen-square, Bloomsbury, W.C.).—3.30 P.M.: Clinical Lecture:—Dr. Beevor: Bulbar Paralysis.

Central London Throat and Ear Hospital (Gray's Inn-road, W.C.).—3.45 P.M.: Demonstration: Mr. Stuart-Low: Middle Ear and Labyrinth.

SATURDAY (18th).—Post-Graduate College (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. 2 P.M.: Medical and Surgical Clinics. X Rays. 2.30 P.M.: Operations.

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 11 A.M.: Eye.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

For the United Kingdom.		To the Colonies and Abroad.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A.—Dr. H. K. Abbott, Fareham; Messrs. Aked and Aked, Lond.; Mr. E. Arnold, Lond.; All-India Hospital Assistants' Association, Parel, Secretary of.

B.—Sir Edward Buck, Lond.; Mr. W. E. Boulter, Plumstead; Mr. W. Bevan-Lewis, Wakefield; Dr. W. Cecil Bosanquet, Lond.; Mr. S. H. Benson, Lond.; Mr. W. Bryce, Edinburgh; Messrs. Barclay, Perkins, and Co., Lond.; Messrs. Burroughs, Wellcome, and Co., Lond.; Bridgwater Hospital, Secretary of; Berrow's Worcester Journal Co., Worcester; Dr. F. Bryan, Buxton; Mr. A. E. Blades, Leicester; Mr. L. Bottomley, Ashton-under-Lyne.

C.—Mr. W. Watson Cheyne, Lond.; Dr. M. Coghlan, Bournemouth; Calyx Manufacturing Co., Lond.; Messrs. Curtis and Henson, Lond.; Messrs. J. and A. Churchill, Lond.; Dr. T. Caverhill, Edinburgh; Cheltenham General Hospital, Secretary of; Mr. F. W. Clarke, Chorlton-cum-Hardy; Dr. J. Michell Clarke, Bristol; Central Public House Trust Association, Lond., Secretary of; Mr. C. G. Cowen, Lond.; Canterbury Borough Asylum, Medical Superintendent of; Rev. Father Campbell, Nottingham.

Situations wanted: First 30 words, 2s. 6d.; per additional 8 words, 6d.

Quarter Page, £1 10s. Half a Page, £2 15s. An Entire Page, £5 5s.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (*to ensure insertion the same week*) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to *advertisements* appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies *only* should be forwarded.

Cheque and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable *to* the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France.—J. ASTIER, 31, Rue Rents, Asnières, Paris.

A Lecture

ON

THE CANCER PROBLEM.

Delivered at the Incorporated Institute of Hygiene on May 14th, 1907,

BY J. BLAND-SUTTON, F.R.C.S. ENG.,

SURGEON TO, AND MEMBER OF THE CANCER INVESTIGATION COMMITTEE OF, THE MIDDLESEX HOSPITAL.

GENTLEMEN,—Whilst the public is persistently asking the profession to explain the nature and cause of the tumour-diseases grouped together for clinical convenience under the general term cancer, some observations have been made which tend to show that physicians and surgeons have failed to grasp the subject in its full meaning. We are still hopelessly ignorant of the cause of cancerous disease and have to rely on histologic methods for distinguishing between the various groups, or kinds, of malignant tumours; on these grounds I think to-day it will be useful to consider the structural details which serve for the identification of a malignant tumour. The ultimate histological analysis of our bodies shows that they, like the bodies of other vertebrates, consist of epithelium, connective, muscular and nervous tissues, and though these tissues present important modifications in different regions of the body and give rise to a great variety of tumours a careful examination of their structure by means of the microscope will enable a competent histologist to state with certainty the kind of tissue in which a particular tumour arose. It is on this account that tumours of all kinds are classified on a structural (or histologic) basis and it is a remarkable fact that nearly every tissue in the body is found in the form of a tumour and every tissue, with the exception of three (fat, voluntary muscle, and nervous tissue), is the source of malignant tumours.

There are five distinct groups of malignant tumours: (1) the true cancers are those which arise from epithelium whether protective or secretory (glandular); (2) the chorion-epithelioma which is derived from the epithelium of the chorionic villi out of which the placenta is formed; (3) the endotheliomata derived from the modified epithelium lining blood and lymph vessels and serous membranes; (4) sarcomata which grow from connective tissue, whether firm and dense like periosteum or so fine as the sustentacular tissue of the retina; and (5) a remarkable group of tumours known as malignant teratomata arising in perversion of the sex-cell (malignant embryomata).

In dealing with these tumours we are confronted with the fact that there is no such thing as an absolute histologic indication of malignancy, clinical and histological characters must be considered together; moreover, in the extensive group of connective tissue tumours, although a typical cartilage tumour, a uterine fibroid, or a myeloma can be distinguished from a sarcoma or a cancer as easily as a decision can be made between a planet and the pole star, there are in every genus of connective-tissue tumours forms which in their minute structure so closely resemble sarcomata that the most expert and experienced microscopists cannot give a confident opinion for or against malignancy. The true character of such tumour can only be determined by careful observation of the patient. It is also necessary to draw attention to the difficulty which is sometimes experienced in deciding between the tumour formations (gummata) of syphilis and sarcomata.

SARCOMATA.

It may be useful to give some examples of the difficulty which arises out of this failure in histological methods and its importance to patients. Many years ago I saw a testicle removed from a young man; on dividing the gland it seemed to me a mistake had been made and that its enlargement was due to a gumma. I begged half the specimen and made it the subject of careful microscopic inquiry which further convinced me that it was a gumma. The operator handed the other half of the testis to a very experienced and skilful histologist who also came to the opinion that the supposed sarcoma was a gumma. Time proved us both in error, and this patient died with secondary deposits in his lungs and abdomen within two years of the operation.

In 1905 I removed the uterus from a woman, aged 40 years, on account of a fibroid as big as an ostrich's egg which had become impacted in the pelvis producing pain in the great sciatic nerve. The patient recovered easily and well. The tumour was moderately hard and displayed the characteristic features of a common fibroid. Some months later the pain in the sciatic nerve returned and a hard diffuse mass could be detected in the pelvic connective tissue; fragments were removed and submitted to three histologists who reported that they exhibited the typical characters of an innocent fibroid. The patient died 14 months after the primary operation; *the apparently innocent fibroid was a spindle-celled sarcoma.*

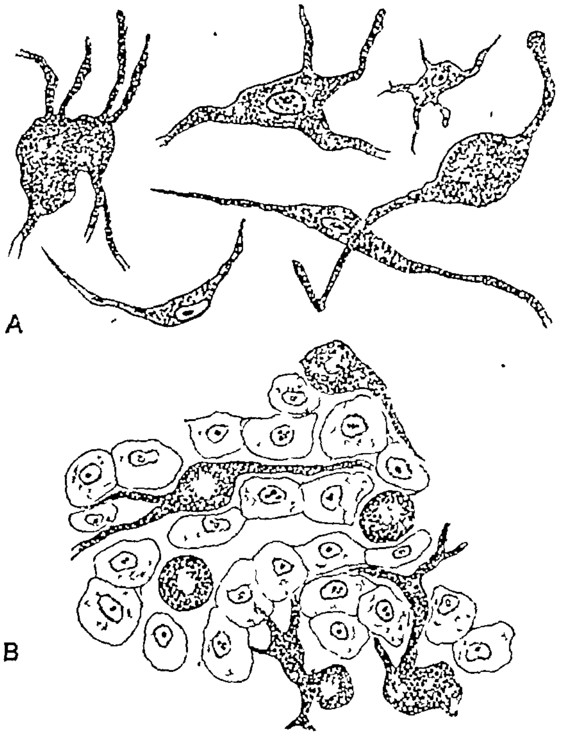
Many years ago, when my attention was closely devoted to the study of odontomes, I received from a veterinary friend a tumour as big as the egg of a turkey which he had removed from the maxillary sinus of a horse; on dividing it I found in the centre a soft pulp instead of the tooth I had hoped for; on microscopic examination the thickness of the tumour mass was found to be composed of dense laminæ of fibrous tissue, but the central pulp consisted of mycelium, and of a kind new to me. I carefully preserved the entire specimen and some years later Mr. A. G. R. Foulerton kindly investigated it and found that the pulp contained a streptothrix. Some years ago such a mass would have been classed among sarcomata. There is, however, a point in which sarcomata differ from all forms of infective tumours arising in connective tissue, as the result of local irritation due to syphilis, actinomycosis, tubercle, or foreign bodies, quite apart from the presence of a local irritant; the tissue resulting from such irritants is always of the simple kind, whereas in some of the sarcomata, especially those arising from periosteum, we meet with hyalin cartilage, well-developed spindle cells, some of them presenting a transverse striation such as is seen in the young cells, which ultimately form transversely striped (voluntary) muscle. The tissue which forms the neutral capsule to a focus of tuberculous or syphilitic infection never passes beyond the condition of simple fibrous tissue and is practically non-vascular, whereas the sarcomata are, as a rule, very vascular, and although in the rapidly growing forms they rarely pass beyond the condition of thin-walled channels yet in the slower growing kinds well-developed blood-vessels may be detected.

The difficulty of distinguishing between chronic inflammatory tissue and sarcomata is one which we may hope will be overcome in the laboratory; in this respect the bacteriologist has had some marked successes. Some years ago we had great difficulty in deciding between a gumma, a sarcoma, or a streptothrix mass; to-day we expect a laboratory worker to find in the first the spirochæta pallida, in the last the streptothrix, and we are full of hope that he will some day in the spindle-celled sarcoma find some distinguishing and easily recognised sign. It is very necessary to discover the cause of these tumours, for at the present time our histologic methods fail us most where they would be of the greatest use—namely, in providing a means of distinction between sarcomatous tissue and the innocent tissue of which so many fibroids of the uterus consist. The peculiar local reaction of the connective tissue in recognised parasitic diseases, whether syphilitic, actinomycotic, or echinococcic, is also a marked feature of some of the most typical cancers, providing them with what is known as the stroma. The formation of a stroma occurs in all malignant tumours except the chorion-epithelioma and is especially marked in the true cancers. The vascularity of sarcomata is an important feature in connexion with their dissemination, because the growth permeates the walls of the veins and the cellular processes project into, and creep along, their lumina much in the same way that an outrunner from a malignant tumour of the kidney will grow into the ureter. When sarcomata grow in the immediate neighbourhood of large veins like the internal jugular or the inferior vena cava and perforate it, the intravenous processes may be as big as the end of a finger, and sometimes a piece may be detached which is too large to pass the right auriculo-ventricular valve and causes sudden death. The part played by the blood stream in disseminating sarcoma is best seen in cases of melano-sarcoma, for the blackness of the pigment renders the secondary nodules particularly conspicuous, and in some instances the skin, viscera, and bones may be dotted with thousands of discrete black dots indicating the lodgment of minute sarcomatous emboli. When the primary growth arises in the skin it will invade the local lymphatic in the same way as cancer and give rise to enlargement of the local lymph glands.

MELANO-SARCOMATA.

Certainly the rarest and most remarkable tumours among the sarcomata are the pigmented species known as melano-sarcomata and they arise from the pigment cells of the uveal tract and of the skin. We have been accustomed to classify these malignant tumours roughly as round-celled or spindle-celled according to the prevailing type of cell visible in magnified sections; but there is another, but very rare, kind detected by Collins, which arises from the glandular epithelial cells in the ciliary body. Ribbert has published some observations (1897) which add great interest to these tumours. When the melano-sarcomata which arise in the choroid are examined by teasing, the cells then assume the stellate forms with which most of us are familiar in the pigment cells so abundant in the skin of frogs and other amphibians and particularly in cuttle-fishes. These are known as chromatophores, and Ribbert would have us so regard these cells in the choroid and in the skin, and he even suggests that the melano-sarcomata might be appropriately termed chromatophoramata. In regard to this it is necessary to point out that the black pigment (melanin) in the pigment cells of vertebrates only agrees (according to MacMunn) with that of invertebrates in the common attribute—blackness. The interest of Ribbert's observations in connexion with the subject of this lecture lies in the fact that in secondary nodules of choroidal melano-sarcomata which were found in the liver and brain, the cells were identical with the chromatophores so characteristic of the lamina fusca element of the choroid. (Fig. 1.)

FIG. 1.



Pigmented stellate cells from a melano-sarcoma. The cells in the lower part of the drawing are from a secondary nodule in the liver; the upper from a metastatic nodule in the brain. The primary tumour in each instance arose in the choroid. Teased specimens (after Ribbert).

These observations not only justify us in assigning these remarkable tumours to the genus sarcomata but furnish us with additional evidence of the object to which this lecture is devoted—namely, to demonstrate that every variety of cell in the human body, even the most specialised, with the three exceptions named (fat, voluntary muscle, and nerve cells), may be the source of a malignant tumour.

CARCINOMA.

The term cancer is now definitely restricted by pathologists to malignant tumours (or growths) arising in epithelium; even with this apparently clear definition difficulties arise not only in regard to the microscopic recognition of malignant epithelium but even in determining what cells are to be included in the term epithelium. Anatomists adopt a compromise and include as epithelium proper the cells clothing the skin, the surface of the alimentary canal from the mouth to the anus, and the cell investment of the genito-urinary organs. The cells lining blood and lymph-vessels and serous membranes—e.g., peritoneum and pleura—are known as endothelium, and finally the extraordinary cells covering the chorionic villi come into the same category and help to set at naught the best endeavours of the classifier. We have to realise that every variety of epithelium, using the term in its broadest sense, may give rise to malignant tumours; it matters not whether it be the coarse protective epithelium on the palm or the sole, the rich columnar cells of the gastro-intestinal tract, or the active covering of the chorionic villi and the delicate endothelial lining of the capillaries and serous surfaces as well as of lymphatics, but beyond all this we have come to realise that even the sex cells in the ovary occasionally display the destructive conditions covered by the term malignancy.

The most remarkable feature of protective and secretory epithelium is its vitality; this is well displayed when portions of it are accidentally detached from the skin by awls, forks, knives, or needles, and imbedded in the cutaneous tissues where it lives and grows, forming, in many instances, a cyst lined with epithelium (implantation cysts). The formation of cysts of this kind is best studied in relation with the eye. Punctured wounds of the cornea made with needles, forks, and even instruments as coarse as a rapier are sometimes followed by small epithelial cysts, and even hair growing on the iris. These cysts are known to arise from portions of conjunctival epithelium and in some cases eyelashes conveyed into the anterior chamber of the eye by the instruments at the time of the puncture. Implantation cysts of this kind are occasional sequelæ to carefully performed operations made to extract cataracts, &c. It is curious to observe that when definite and skilfully planned experimental grafts have been placed on the iris of rabbits it is rare that they survive, and even when they appear to take root, so to speak, it is only temporary and they either disappear or more frequently become extruded from the eyeball.

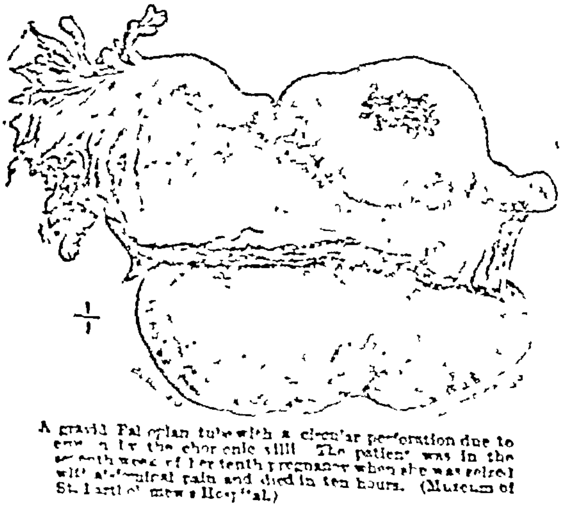
This vitality of epithelial cells is even more marked in those derived from cancers and the rate at which displaced cancer cells multiply depends in a very large measure on their environment. In discussing this part of the subject it will be shown that this attitude of the cancer cell to favouring situations has some interesting and important clinical aspects. In the first place it is necessary to point out that there is nothing specific about a cancer cell, nothing which would enable even the most expert pathologist to recognise it if placed singly under the microscope. In order to identify a cancerous growth it is necessary to have a section prepared from the suspected tissue and appropriately stained so that the arrangement or grouping of the tissues composing it can be studied before a reliable opinion can be formed in regard to it; even then in many instances doubt and difficulties arise, and it is quite a common thing for men of equal experience to differ in opinion as to the malignancy or otherwise of a given section of a suspected cancer.

Another feature manifested by cancerous cells is their aggressive or erosive property. The majority of simple (or non-malignant) tumours are invested by a capsule of fibrous tissue which in a measure isolates them from the surrounding tissues in which they are imbedded, but in nearly all malignant tumours this investment is wanting and the cells are free to invade or permeate the parts immediately adjacent, and in this way the tissues, whether they be soft like muscle, fat, or mucous membrane, are quickly invaded, eroded, and destroyed. This erosive action is well seen where cancer comes into relation with bone, for even this tough tissue is destroyed and the growth permeates it, forming bays and recesses even in its toughest parts. This destructive action of the cancer cell is a source of grave danger, for when a large blood-vessel or an air passage or a serous cavity is implicated by cancer the walls of these structures are destroyed, leading to serious consequences, such as bleeding, difficulties with respiration, or infection of the great cavities of the body, which lead sooner or later to grave disasters. Moreover, it is this erosive action which lies at the bottom of the peculiar feature displayed by malignant tumours known as dissemination (metastasis). In many parts of the body epithelial cells are very active; some, as in secreting glands, take from the blood material which they elaborate and then excrete for the use of the organism, a process termed for convenience metabolism: this in the ordinary affairs of life we call the making or manufacture of a substance. In the intestine the columnar cells withdraw directly from the digested food fat for conveyance into the lacteals; hence when these cells become cancerous they remain active but with perverted function, and they digest the natural tissues of the host and grow at the expense of his body. The best example of the aggressiveness of epithelium under normal conditions is that possessed by the cells of the chorionic villi. We have lately come to learn that it is one of the prime duties of this epithelium to erode the decidua in order to enable the oösperm (fertilised ovum) to imbed itself into the uterine tissues and bring about a firm fastening for the tissues which are ultimately to become a placenta. Under normal conditions this is effected without much disturbance. We have come to learn that under abnormal conditions this erosive or destructive action of these curious villi may become excessive and disastrous and the villi themselves are liable to behave in every respect like, and may actually become, a malignant tumour.

The aggressiveness of these cells is easily studied in the early stages of pregnancy in a Fallopian tube; when the oösperm settles on the tubal mucous membrane the chorionic villi quickly penetrate it and burrow into the muscular layer penetrating to the serous covering, and even this may be perforated by them and the villi project freely into the peritoneal cavity. This is shown in an exquisite manner by a gravid tube in the Museum of St. Bartholomew's Hospital. The parts were removed from a patient in the seventh week of her tenth pregnancy; she was seized with pain and signs of internal hæmorrhage and died in ten hours. The specimen shows a fairly circular perforation of the wall of the tube with the delicate chorionic villi projecting through it. (Fig. 2.)

In the uterus this perforating power of the chorionic epithelium is most destructively displayed when the villi are in the condition known as hydatidiform disease and cases have been observed and reported in which the villi have perforated the muscular and serous coats of the uterus, and processes of the villi have projected in several places from the serous coat of the uterus, as in the gravid tube depicted in Fig. 2. The uterus, especially when gravid, contains large blood channels and in the course of the erosion processes of the villi find their way through the walls of these blood-vessels, especially the venous channels, and project like buds into the lumina and the blood current detaches the surface cells, sets them free into the blood stream, and they become deported to the lungs or elsewhere as emboli. When the hydatidiform change is malignant (chorion-epithelioma) these cellular emboli give rise to new foci of the disease (secondary or metastatic nodules) in the organs in which they may chance to be arrested. We have, then, in this [illegible] a review of one of the routes by which cancer disseminates, but it is not the only way, but before considering this matter it will be worth while to discuss the relation of cancerous invasion of blood and lymph vessels as well as the behaviour of the blood itself to the invading cancer cells.

FIG. 2.

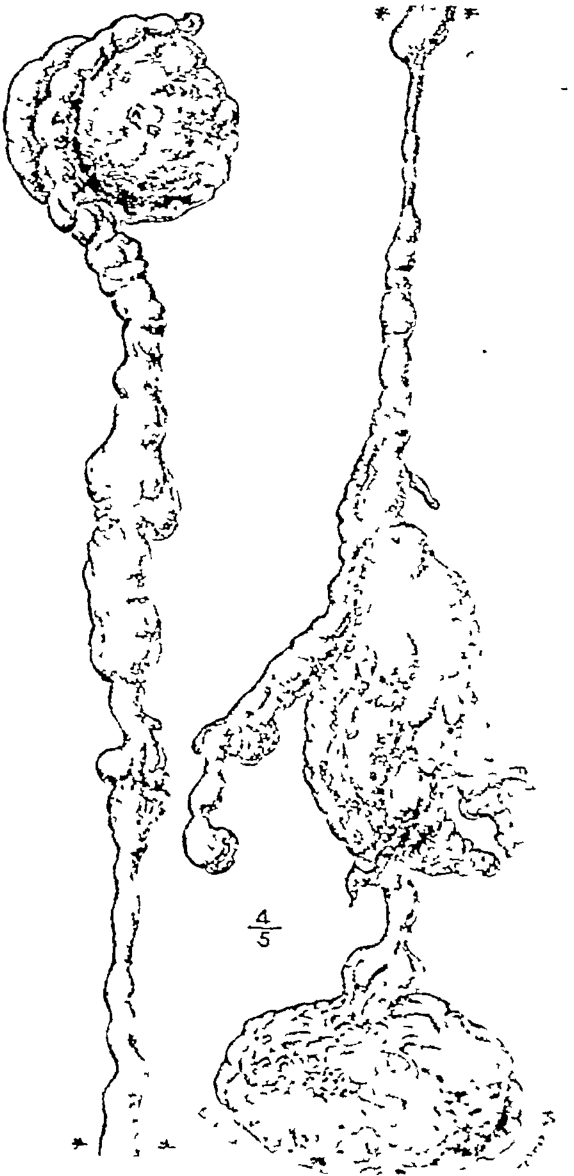


A gravid Fallopian tube with a circular perforation due to erosion by the chorionic villi. The patient was in the seventh week of her tenth pregnancy when she was seized with abdominal pain and died in ten hours. (Museum of St. Bartholomew's Hospital.)

DISSEMINATION.

In reflecting on the dissemination of cancer by the blood-stream it has often struck me, as it must certainly have occurred to others, that minute cancerous particles ought theoretically to be present in the blood stream and often in considerable number in order efficiently to account for the multitude of secondary nodules sometimes found in cancerous individuals, especially if allowance be made for a proportion which fail to grow after their arrest. No one so far as I know has ever detected in the course of an examination of blood withdrawn from a living person microscopic cancerous particles. That cancer does involve the walls of blood-vessels and even the thoracic duct is well known, and an excellent example of this is represented in Fig. 3; the receptaculum chyli and the thoracic duct are solid throughout in consequence of cancerous

FIG. 3.

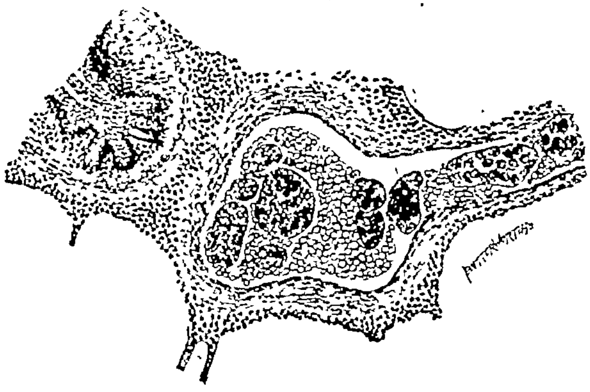


A thoracic duct and receptaculum chyli permeated throughout by cancer. The primary growth arose in the rectum. The specimen described and figured by Hilton is in the Museum of the Middlesex Hospital.

implication of its walls. In this instance the primary cancer arose in the rectum. A microscopic examination of the thoracic duct shows that its lumen is not merely blocked with cancerous elements resembling clot in a thrombosed vein but its walls are infiltrated and their proper tissue replaced by the cancerous tissue. Several careful descriptions of similar specimens have been described where the primary focus was situated in the stomach, uterus, or rectum. It is a curious and unexpected feature of cancerous blocking of the thoracic duct that it does not lead to any symptom indicating obstruction to the flow of chyle into the innominate vein. This is also the case when in the course of an operation at the root of the neck on the left side the duct has been injured such injury is followed by a flow of chyle and the patient rapidly emaciates; if then the duct be ligatured no inconvenience is produced and the patient recovers without any permanent ill-effects. A study of cancerous infiltration of the thoracic duct throws clear light on the enlargement of the lymph glands at the root of the neck, which is a frequent clinical feature of cancerous disease of the lower section of the œsophagus and stomach. A large hard lymph gland in the neck just above the clavicle in an obscure abdominal case has been considered for many years as an indication of the existence of cancer in, or in the near neighbourhood of, the stomach.

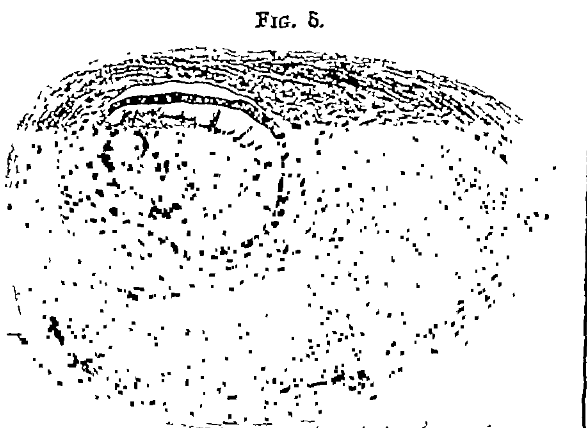
No observer has attempted to deny that cancer cells enter the blood stream; they gain access to it by implicating small veins, or by way of the lymphatics, and enter it through the thoracic duct; few observers have succeeded in determining what happens to the cancer particles which succeed in passing into the blood stream. Some observations of great interest in *relation to this* have been made by M. B. Schmidt (Jena) which go to show that the blood is in a sense *hostile to such particles*, and his observations show that embolic infection of the lungs occurs with great frequency when *cancer occurs primarily* in the abdominal viscera, and that the nodules may be abundant in the pulmonary vessels yet the lungs appear normal to the naked eye.

FIG. 4.



A pulmonary capillary containing cancerous emboli (after Schmidt).

FIG. 5.



A cancerous embolus in a pulmonary capillary imbedded in a thrombus (after Schmidt).

The behaviour of the blood to cancerous intrusions as investigated by Schmidt is quite remarkable. When the cells enter the blood they excite thrombosis and the *thrombus contracts upon the cancer cells* and may ultimately destroy them. (Figs. 4 and 5.) Goldmann has also *shown that the thrombosis of the blood* in a vein implicated by cancer may serve as a barrier to cancerous invasion of the *blood contained in it. This defending power* of the blood is a very important fact, as it prevents the blood-stream from being *colonised, and the destructive power* of the blood in relation to cancerous emboli offers, as Handley points out, an *explanation of the fact* established by Teacher, that chorion-epithelioma, the only cancer certainly known to spread *habitually by the blood, ends oftener* than any other form of cancer in spontaneous cure, after incomplete operations on the *primary growth*. The detection of *this* prophylactic action of the blood against cancerous particles is very important and as interesting as its phagocytic action against bacterial invasion.

PERMEATION.

In opposition to the old idea that the dissemination of cancer throughout the body depends on the invasion of the blood, and which is no longer tenable, we must accept the conclusions formulated by Mr. W. S. Handley as a result of careful investigation on the spread of cancer by way of the lymphatics. This observer has made a painstaking investigation of the relation of cancer, particularly in relation to lymphatics, and shows that when cancer implicates or permeates lymph-vessels it does not excite thrombosis and that the dissemination of the cancer takes place almost entirely by the lymphatics. The outcome of this investigation is of very great value and throws some light on some otherwise unaccountable complications of cancer which are of clinical value. Handley has shown that when the breast is attacked by cancer the cells implicate the lymphatics in the underlying fascia and slowly invade them, and in an insidious way spread throughout the body not only centrifugally, but where the fascia *comes into relation* by means of lympathics with the great cavities of the body, pleural and peritoneal, the *cells spread to the serous* membrane and in time cells invade the cavities and becoming *engrafted upon the serous surface* of lungs, liver, intestines, omentum, and the like, find an environment admirably *suited to their multiplication*.

There is one aspect of these important observations which has a peculiar interest for me. From the earliest part of my professional career I have taken a deep interest in the pathology and surgery of the abdominal and pelvic viscera, and for many years I was puzzled by the fact that although when cancer arises in organs like the breast, eyeball, or testicle, tongue, or lip, it is almost invariably unilateral, whereas in the case of the ovary carcinoma is usually bilateral. This led me to suspect that in many instances bilateral cancer of the ovaries might be secondary, especially as it was recognised in the course of post-mortem examinations that nodules of cancer in the ovary were of frequent occurrence in individuals dying from this disease attacking the breast or the stomach primarily; even then the frequency with which secondary masses of mammary or gastric cancer attacked both ovaries was a striking feature. The cases, however, which more particularly arrested my attention were those in which the ovaries formed large masses, sometimes almost as big as a football, and in which there were no suspicion that a primary focus existed elsewhere. Handley's observations, however, show us that when the cancer cells creep along the fascia and find their way to peritoneum, especially in the neighbourhood of the epigastrium and umbilicus, in which situation they come into relation with the round ligament of the liver and then invade the peritoneum, the cells colonise the peritoneal fluid and by force of gravity find their way into the pelvic cavity and become implanted on the ovaries and the uterus. It is clear that the ovaries offer a favourite nidus for the growth of cancer cells. It is now an established fact that a large proportion of the cases of bilateral cancerous ovaries are examples of engrafted or sown cancer and they are *often secondary to* carcinomatous infection of the gastro-intestinal tract. In years gone by many of the patients from whom bilateral *malignant* tumours of the ovary have been removed died with signs of intestinal obstruction, often *within a few months of the* ovariotomy, and the opinion used to be held that this was due to recurrence or dissemination of the growth; now we know that it is the other way about—the patient has had a slowly growing primary cancer in the pylorus or the colon, situations where carcinoma is often of notoriously slow growth; permeation of the gastric or intestinal walls slowly continues and then the peritoneum is invaded and the peritoneal fluid colonised; the cancer cells, finding a favourable nidus in the ovaries, give rise to large cancerous masses obvious to the simplest methods of clinical examination. The proof that these bilateral malignant ovarian tumours are secondary depends on the fact that their microscopic characters vary with the situation of the primary tumour; if the breast be the primary seat the masses in the ovaries will be identical with mammary cancer; if in the gastro-intestinal tract they will exhibit the structural characters of pyloric, colic, or rectal cancer, as the case may be.

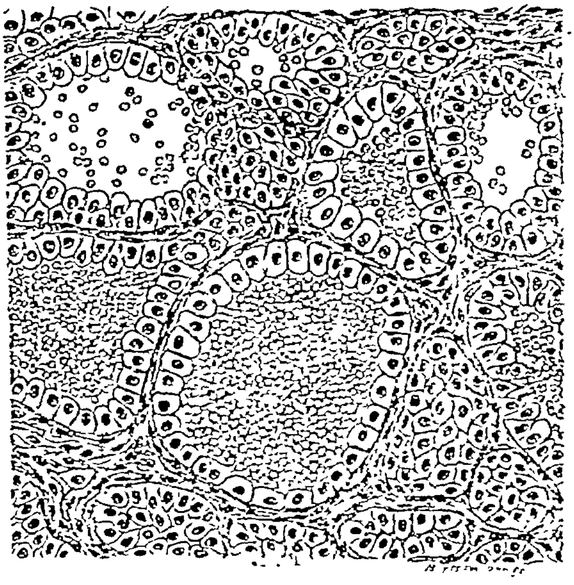
In one year I had the opportunity of studying five examples of this complication and among these patients one was a woman, 59 years of age, who had a large abdominal mass furnishing the clinical signs of an ovarian tumour associated with symptoms of intestinal obstruction. After a careful examination of the patient I came to the conclusion that she probably had cancer of the colon with secondary masses in the ovaries. I succeeded in removing the large bilateral ovarian tumours, one of which was as big as the woman's head and the other equalled her fist in size. On carefully examining the intestines I found a cancer at the ileo-cæcal valve and in order to prevent her dying from intestinal obstruction I joined a loop of ileum by a lateral anastomosis with the ascending colon. The patient made an excellent recovery and was known to be alive six months later. The structure of the ovarian tumours corresponded with that of a typical cancer of the colon.

Like many other workers who have devoted attention to the histology of tumours, I have been greatly perplexed by the identity of the secondary growths with the primary tumour, which in many instances is so complete that a competent histologist on examining microscopically a secondary nodule of cancer in the skin, brain, or in the eyeball can tell with reasonable, and occasionally with absolute, certainty that the primary growth arose in the breast, the stomach, or the rectum. Now we know that in the majority of instances cancer is disseminated by permeation and that the metastatic deposits are actually due to transplantation of fragments of cancerous tissue, it ceases to be surprising that these grafts should give rise to tumours like those to which they originally belonged, any more than that a twig of rue or a sprig of rose should if it take root produce a rue bush or a rose tree. It is, however, a matter of common observation that there are certain situations and organs in the body which are extremely favourable to the vitality of cancerous particles and in this particular the parable of the sower applies as well to the sowing of cancer cells as to the dispersal of seed. In the case of cancer, the liver and the ovaries are the most fertile situations in which cancerous particles can lodge. In regard to the liver Hillier suggests that the massive formations of secondary cancer so often seen in this organ may depend on its large size, small proportion of connective tissue, and its abundant blood-supply copious and rich with food products. Cancerous growths contain a large amount of glycogen and this substance existing in the hepatic cells may also be a favouring condition.

ENDOTHELIOMATA.

From the histologist's point of view there is no difficulty in distinguishing between typical examples of cancer and sarcoma, but there is a remarkable group of tumours displaying malignancy but in this respect holding an intermediate position between the cancers and sarcomata which arise from endothelium, and named in consequence endotheliomata. Tumours of this group arise from endothelium lining blood-vessels, lymph vessels, and serous membranes, and they are divided into species according to the primary structure from which they start: thus, a tumour arising from the endothelium of a blood-vessel would be a hæmendothelioma (Fig. 6), and one originating from lymphatics would be termed a lymphendothelioma. Such tumours are not uncommon in connexion with the gums and the nasal mucous membrane; the salivary glands, especially the parotid; and they are met with in the skin, starting from moles and warts. Endotheliomata also arise from the pleura and peritoneum. The majority of the tumours now classed as endotheliomata were formerly assigned to the sarcomata, and the interesting species now known as perithelioma was identified by Ziegler as angeio-sarcoma and regarded as a sarcoma arising from the walls of arterioles. Its microscopic structure is well shown in Ziegler's well-known drawing (Fig. 7) taken from a specimen which occurred in the thyroid gland. I have recently removed a perithelioma of this kind which grew in the gall-bladder.

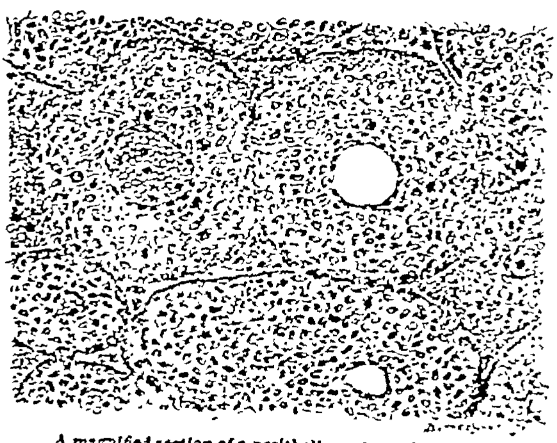
FIG. 6.



A magnified section of an endothelioma from the kidney (after Ziegler).

It is possible that the malignant tissue in a perithelioma arises from the perivascular lymphatics. Although from the clinical point of view the endotheliomata may for convenience rank with the sarcomata, they possess well-marked histologic features and are worth careful study, but in connexion with the object of this lecture they are especially interesting inasmuch as they prove that the inconspicuous flattened epithelium (endothelium) lining small blood- and lymph-vessels is liable, like the large columnar cells of the intestine and the active secreting cells of a gland, or the aggressive epithelium of the chorionic villus, to take on a malignant action and form a tumour which may in the course of a few months destroy the life of the individual. Some endotheliomata are of very slow growth and may exist for 20 years or more merely causing unsightliness, then without any obvious reason grow rapidly and kill.

FIG. 7.



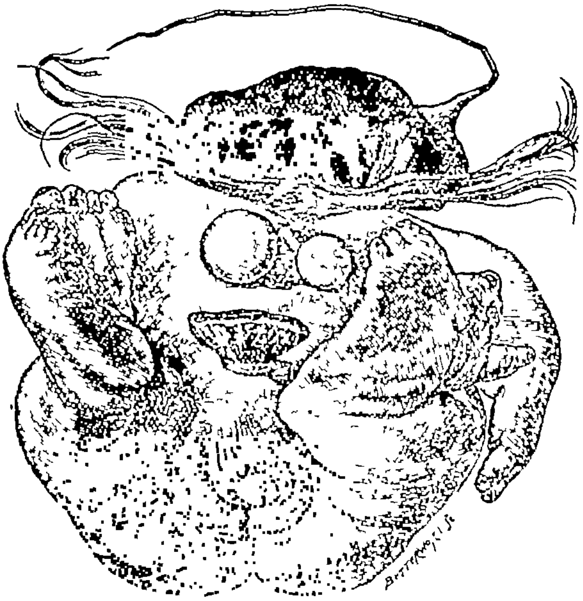
A magnified section of a perithelioma from the thyroid gland (after Ziegler).

MALIGNANT EMBRYOMATA.

Up to this point I have endeavoured to show that when any cell in the body exhibits malignant changes it is thereby impelled not merely to multiply but it assumes constructive functions; thus connective-tissue cells under this impulse not merely forms more connective tissue but they may produce hyaline cartilage, bone, and even striated muscle tissue. Glandular epithelium under malignant stimuli will reproduce the pattern of the gland to which it belongs—mammary, colic, uterine, thyroid, or the like. We now proceed to discuss an even more remarkable aspect of malignant construction—namely, that manifested by the sex cells.

It has been long recognised that homologous twins are the production of a single ovum, and it also is known that those remarkable twin aberrations in which the second individual hangs like a parasite to an otherwise normal individual is, so far as concerns the autosite, an absolutely harmless though often a highly inconvenient partnership in cases where the undeveloped twin is attached externally. More rarely the undeveloped twin occupies one of the great internal cavities of the body (pleura or peritoneum) and is then termed an internal teratoma. Some recent observations have indicated that internal teratomata are by no means harmless. Internal teratomata are found occasionally in any of the great cavities of the body, including the cranium, thorax, abdomen, and pelvis. In the cranial and thoracic cavities they are rarely more complex than a dermoid, such as is so common at the angle of the orbit. In the thoracic cavity they may contain formed organs, and in the abdomen they have been found to possess such completely formed limbs that there can be no doubt concerning their nature. A remarkable example of this is shown in Fig. 8.

FIG. 8.



An internal teratoma from the abdominal cavity (after Young, 1808).

Internal teratomata of this character are usually contained in a cyst. These highly developed internal teratomata we have always been accustomed to regard as perfectly innocent masses but our belief in this received a rude shock when Ritchie described an example which occupied the mediastinum and destroyed the life of a man 24 years of age. A microscopic examination of this tumour disclosed the presence of tissue identical with that seen in the malignant chorion-epithelioma and it had given rise to secondary deposits in the liver and lungs.

In dealing with parasitic fœtuses and teratomata a great difficulty arises, for, strange as it may sound, these tumours in their typical forms are as easily distinguished from the common dermoid as a butterfly from a buttercup, and arise like homologous twins from dichotomy of the sex cell (ovum), yet in their simplest forms they are so difficult to distinguish that it is impossible to assign them with certainty to a particular genus; it is to my mind one of the most remarkable facts in relation with malignancy to find a group of tumours with a well-developed twin at one end and a highly malignant tumour at the other. It is true that every genus of the so-called benign tumours (except lipomata) contains varieties which shade away indefinitely from the type species and display malignancy, but there is nothing in the whole range of oncology so remarkable as the malignant aberrations of tumours derived from the sex cells. We have yet to consider the embryomata. It has been maintained by several writers during the past 15 years, myself among them, that dermoids of the ovary differ in so many respects from those found in connexion with the embryonic fissures (sequestration dermoids) that they have a distinct genetic origin and the results of modern investigation serve to show that there is a complete series between the simple single chambered ovarian cyst and the very complex ovarian embryoma which contains in a confused heap all the tissues which compose the body, including muscle, nerve, and specialised epithelial stuff like enamel-organs and retinal pigmented cells. Moreover, we have come to recognise, thanks to Wilms, that even the simplest ovarian dermoid contains evidence of its origin from a sex-cell (ovum). These tumours consist of a cavity filled with grease and shed hair; at one part of the cyst wall there is usually a skin-clad area of variable extent covered with hair; associated with this surface there is usually an embryonal rudiment in the form of a teat or nipple-like process (pseudo-mamma); its size varies greatly, and often it is inconspicuous and easily overlooked; in others it is so large as to strike the eye of the least observant. The tissues in this embryonal rudiment are often most diverse; I have found fat, cartilage, bone, muscle, nerve, epithelium of all kinds, thyroid gland, teeth, hair, sebaceous glands, and retinal epithelium. It is now maintained by some writers that the embryonal rudiment represents the imperfect development of a sex cell and that the cyst has formed around it in response to the irritation and accumulation of the hair and shed epithelium and grease. There is another variety of ovarian dermoid which manifests itself as a solid growth with small cystic spaces dotted throughout and there is no definite limiting cyst wall. When the solid parts of these tumours are examined they exhibit in confusion the elements of an adult body in the form of glands, epithelium, teeth and hair in process of development, nervous tissue, and connective tissue in all stages of growth, &c. It is useful to refer to these as "solid embryomata" or teratomata in contrast to the common form of ovarian dermoid which may be termed "cystic embryoma" of the ovary. The relationship of the two conditions is shown in the fact that a cystic embryoma and a solid embryoma may co-exist in the same ovary. There is, however, a great clinical difference in the behaviour of these two varieties of ovarian embryomata, for observation has taught us that the solid variety is an intensely malignant tumour.

I have always regarded the typical ovarian dermoid (cystic embryoma) as one of the most benign tumours which attack woman. There is an interesting phenomenon connected with them requiring consideration and which I named epithelial infection. It has been observed in association with a dermoid which has burst into the peritoneal cavity that the serous membrane has been dotted with minute nodules furnished with tufts of hair; some of them were sessile on the peritoneum and others hung on slender pedicles or lodge among adhesions. This condition may be explained by regarding the nodules as arising from the epithelium shed by the burst cyst becoming engrafted on the surface of the peritoneum; moreover, a careful histologic examination of the sessile nodules shows that the connexion is in the nature of a graft, for the tissues of the nodules do not infiltrate the membrane on which they grow.

In the case of solid embryomata the story is different, for it has been discovered that when these tumours exhibit malignancy they manifest it like the true cancers—that is, by dissemination and recurrence after removal. The metastatic deposits in the peritoneum may take the form of grafts, as in the case of cystic embryomata but in the deadly forms the metastasis is probably due to the circulation, because in some instances secondary deposits have been found in the lungs, brain, and in the substance of the liver. The remarkable feature in connexion with malignant embryomata is the complex character of the secondary deposits, for they may contain like the parent tumour hair, glands, hyaline cartilage, and occasionally neuroglia and nerve cells. A large proportion of the recorded examples of these tumours occur in girls and among the recorded cases (about 20 in all) half the number of the patients were under 16 years. The youngest patient was four and the oldest 30 years of age. the earliest examples was observed by Jessop (1871) in a girl of 13 years.

It must not be forgotten that those large multilocular tumours of the ovary which are best described as ovarian adenomata, and the loculi of which are lined with large mucin cells, behave exactly like the hair-bearing embryomata, for they sometimes burst and infect the peritoneum with cells which engraft themselves on the serous membrane, but there are varieties which behave like the malignant solid ovarian embryoma and recur rapidly after removal, disseminate widely, and destroy the patient in a few months. The interest which surrounds this group is due to the fact that we have to deal with tumours arising in the epithelium of the ovarian follicle and in the sex cells which may be as benign as simple fatty tumours, or as malign as the deadliest cancers or sarcomata and yet capable of producing the most complex and specialised tissues found in the body, not merely in the tumours themselves but in the metastatic nodules which they originate; thus any theory invented to account for sarcomata and carcinomata, and in fact any form of malignant tumour, will have to explain these extraordinary aberrations of the sex cells.

We have hitherto believed that the sex cells (ova) remain passive until they are stimulated into activity by a spermatozoon; there are reasons for believing and observations which support the belief that asexual division may occur whilst the ovum is still in its follicle, and a fair amount of activity prevails among the chromosomes of ova immediately preceding their maturation. These changes are important in connexion with the remarkable cytological observations of Farmer, Moore, and Walker in regard to the gametoid type of cell division which occurs in the essential cells of malignant tumours. Observations of this kind tend to place speculations on the cause of malignant disease in a new light, for we must now realise not only that it is something which exercises a malign influence on the cells of formed tissues, but it has a potent influence even on the sex cells, and that the liability to malignancy besets every cell of the body from the earliest period of embryonic life to extreme old age.

A Clinical Lecture

ON

PELVIC APPENDICITIS WITH PAR-APPENDICAL ABSCESS AND CYSTITIS.

Delivered at the General Hospital, Birmingham, on Feb. 8th, 1907,

BY GILBERT BARLING, M.B. LOND., F.R.C.S. ENG.,

SURGEON TO THE HOSPITAL.

GENTLEMEN,—At my last ward demonstration I discussed with you the case of this patient because of some unusual features which it presented and because of the difficulties in diagnosis which it provided. When we first met to consider the case you had an opportunity of examining the patient under an anæsthetic and so of interrogating with your own fingers the local condition present in the lower abdomen and pelvis. The trouble for which the man was admitted to hospital was a most striking cystitis and I ventured to tell you at the examination that the explanation of his illness would be found in his abdominal cavity and that he would have to be treated by abdominal section. To-day I am able positively to confirm this opinion and I propose to go fully over the whole case again, not only because of its extreme interest per se, but because it illustrates a serious condition which has not received the recognition due to it.

The patient is a male, aged 42 years, sallow and anæmic, volatile, neurotic, and very difficult to obtain a connected history from; he wishes, as many patients of this type do, to interpret his own symptoms and to explain away any that he thinks are threatening; this, I believe, is responsible in part for the delay in recognising the nature of his disease. He tells us that his bladder symptoms first arose in January, 1906, when he "caught cold"; this caused him to micturate frequently and with pain, whilst he had also pain across the loins. He was told by his medical adviser that he was suffering from cystitis; later both testicles swelled and became very painful and in the opinion of a physician the patient was suffering from gout. The illness on this occasion lasted 23 weeks, after which time he resumed his duties as a clerk and continued to work steadily until admission to hospital on Jan. 23rd, 1907, though he felt ill and from time to time sought medical advice. We learn that his bladder has been sounded for stone on two occasions and according to his own account he has received many different diagnoses of his case. For the last two months the acute condition in his bladder from which he suffered a year ago has returned, there has been very frequent and painful micturition day and night, and the urine has been very offensive. The patient's past history tells much of interest when it has been cleared of verbiage and explanations. Ten years ago he experienced an attack of acute abdominal pain in the region of the umbilicus, lasting from three to four days; it was accompanied by vomiting and followed by constipation only overcome by strong aperients. Since that time many such attacks have occurred, on the average about three in a year, some quite slight, others more severe, the worst compelling him to stay in bed for a fortnight. The only other points in the history are a statement that he was treated for syphilis by a quack, but there is little probability that he really suffered from this disease, and there is certainly no evidence than he did. Rheumatic fever occurred at five years of age. Summing up all these details it seems clear that the patient had cystitis for the first time a year ago, that he has since not been entirely free from it, though he has for the last few months managed with difficulty to go on with his work. Prior to the cystitis he had numerous acute abdominal attacks spread over years and recurring at varying intervals up to the present time.

On examination the lower abdomen was full but not rigid, just inside the brim of the pelvis on the right side some slight thickening could be detected, but the right iliac fossa was free from tenderness and swelling. Per rectum the finger detected much thickening and infiltration of the anterior rectal wall and the base of the bladder behind the prostate, some fulness was felt on the right side, but on the left a large dense mass of much greater extent than on the right; it was fixed, leathery in consistence, and non-fluctuating, whilst the rectal mucous membrane was free from œdema. Cystoscopic examination detected only a diffuse inflammatory condition of the mucous membrane of the bladder, no ulceration was observed, nor any abscess discharging into the bladder. The testicles appeared to be healthy and no nodules suggestive of tubercle could be detected in either. Examination of the urine showed a large amount of pus but tubercle bacilli were not found. The patient's temperature was 100° F. on admission and the pulse ranged from 60 to 90.

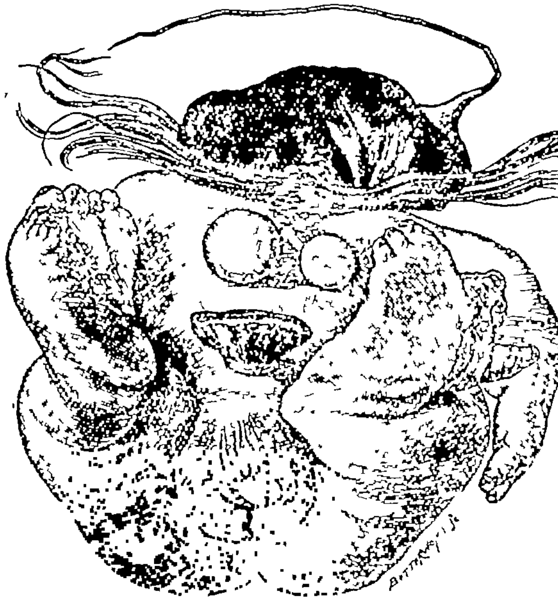
Our investigation so far appeared to show that the cystitis was not tuberculous in origin, ulceration of the bladder was absent, no tubercle bacilli could be found in the urine, and there was no evidence of tubercle elsewhere in the patient's system. I lay stress on these points because the dense thickening felt per rectum was consistent with a tuberculous peritonitis which provides so many surprises in the abdominal cavity. The absence of calculus and of tumour in the bladder as the cause of the cystitis had also been demonstrated. I pointed out at our first examination of the patient the probability that the key to his present condition was to be found in his past history of acute abdominal attacks; these were very suggestive of attacks of appendicitis. The absence of an inflammatory thickening in the right iliac fossa was not inconsistent with this, for in many patients the appendix lies in the pelvis and in that cavity we find the result of the inflammatory process, pus and adhesions, which have their starting-point in appendical inflammation. To-day I am able to confirm this view from what was found at the operation performed five days ago. The abdomen was opened in the middle line just above the pubes; the vermiform appendix was found densely adherent on the right side of the pelvis and surrounded by a collection of pus which amounted to a few drachms. Further stripping of adhesions

MALIGNANT EMBRYOMATA.

Up to this point I have endeavoured to show that when any cell in the body *exhibits malignant changes it is thereby impelled* not merely to multiply but it assumes constructive functions; thus connective-tissue cells under this impulse not merely *forms* more connective *tissue* but they may produce hyaline cartilage, bone, and even striated muscle tissue. Glandular epithelium under malignant stimuli will reproduce the pattern of the gland to which it belongs—mammary, colic, uterine, thyroid, or the like. We now proceed to discuss an even more remarkable aspect of malignant construction—namely, that manifested by the sex cells.

It has been long recognised that homologous twins are the production of a single ovum, and it also is known that those remarkable twin aberrations in which the second individual hangs like a parasite to an otherwise normal individual is, so far as concerns the autosite, an absolutely harmless though often a highly inconvenient partnership in cases where *the undeveloped twin is attached externally*. More rarely the undeveloped twin occupies one of the great internal cavities of the body (pleura or peritoneum) and is then termed an *internal teratoma*. [Some recent observations have indicated that internal teratomata are by no means harmless. Internal teratomata are found occasionally in any of the great cavities of the body, including the cranium, thorax, abdomen, and pelvis. In the cranial and thoracic cavities they are rarely more complex than a dermoid, such as is so common at the angle of the orbit. In the thoracic cavity they may contain formed organs, and in the abdomen they have been found to possess such completely formed limbs that there can be no doubt concerning their nature. A remarkable example of this is shown in Fig. 8.

FIG. 8.



An internal teratoma from the abdominal cavity (after Young, 1808).

Internal teratomata of this character are usually contained in a cyst. These highly developed internal teratomata we have always been accustomed to regard as perfectly innocent masses but our belief in this received a rude shock when Ritchie described an example which occupied the mediastinum and destroyed the life of a man 24 years of age. A microscopic examination of this tumour disclosed the presence of tissue identical with that seen in the malignant chorion-epithelioma and it had given rise to secondary deposits in the liver and lungs.

In dealing with parasitic fœtuses and teratomata a great difficulty arises, for, strange as it may sound, these tumours in their typical forms are as easily distinguished from the *common dermoid* as a butterfly from a buttercup, and arise like homologous twins from dichotomy of the sex cell (ovum), yet in their simplest forms they are so difficult to distinguish *that it is impossible* to assign them with certainty to a particular genus; it is to my mind one of the most remarkable *facts in relation* with malignancy to find a group of tumours with a well-developed *twin at one end* and a highly malignant tumour at the other. It is true that every genus of the so-called benign tumours (except lipomata) contains varieties which shade away indefinitely from the type species and display malignancy, but there is nothing in the whole range of oncology so remarkable as the malignant aberra*tions of tumours derived from the sex cells*. We have yet to consider the embryomata. It has been maintained by several writers during the past 15 years, myself among them, that dermoids of the ovary differ in so many respects from those found in connexion with the embryonic fissures (sequestra*tion dermoids*) that they have a distinct genetic origin and the results of modern investigation serve to show that there is a complete series between the simple single chambered ovarian cyst and the very complex ovarian embryoma which contains in a confused heap all the tissues which compose the body, including muscle, nerve, and specialised epithelial stuff like enamel-organs and retinal pigmented cells. Moreover, we have come to recognise, thanks to Wilms, that even the simplest ovarian dermoid contains evidence of its origin from a sex-cell (ovum). These tumours consist of a cavity filled with grease and shed hair; at one part of the cyst wall there is usually a skin-clad *area of variable extent covered with hair; associated with* this surface there is usually an embryonal rudiment in the form of a teat or nipple-like process (pseudo-mamma); its size varies greatly, and often it is inconspicuous and easily overlooked; in others it is so large as to strike the eye of the least observant. The tissues in this embryonal rudiment are often most diverse; I have found fat, cartilage, bone, muscle, nerve, epithelium of all kinds, thyroid gland, teeth, hair, sebaceous glands, and retinal epithelium. It is now maintained by some writers that the embryonal rudiment represents the imperfect development of a sex cell and that the cyst has formed around it in response to the *irritation and accumulation of* the hair and shed epithelium and grease. There is another variety of ovarian dermoid which manifests itself as a solid growth with small cystic spaces dotted throughout and there is no definite limiting cyst wall. When the solid parts of these tumours are examined they exhibit in confusion the elements of an adult body in the form of glands, epithelium, teeth and hair in process of development, nervous tissue, and connective tissue in all stages of growth, &c. It is useful to refer to these as "solid embryomata" or teratomata in contrast to the common form of ovarian dermoid *which may be termed* "cystic embryoma" of the ovary. The relationship of the two conditions is shown in the fact that a cystic embryoma and a solid embryoma may co-exist in *the same ovary*. There is, however, a great clinical difference in the behaviour of these two varieties of ovarian embryomata, for observation has taught us that the solid variety is an *intensely malignant tumour*.

I have always regarded the typical ovarian dermoid (cystic embryoma) as one of the most benign tumours which attack woman. There is an interesting phenomenon connected with them requiring consideration and which I named epithelial infection. It has been observed in association with a dermoid which has burst into *the peritoneal cavity* that the serous membrane has been dotted with minute nodules furnished with tufts of hair; some of them were sessile on the peritoneum and others hung on slender pedicles or lodge among adhesions. This condition may be explained by regarding the nodules as arising from the epithelium shed by the burst cyst becoming engrafted on the surface of the peritoneum; moreover, a careful histologic examination of the sessile nodules shows that the connexion is in the nature of a graft, for *the tissues* of the nodules do not infiltrate the membrane on which they grow.

In the case of solid embryomata the story is *different*, for it has been discovered that when these tumours exhibit malignancy they manifest it like the *true cancers*—that is, by dissemination and recurrence after removal. The *metastatic* deposits in the peritoneum may take the form of grafts, as in the case of cystic embryomata but in the deadly forms the metastasis is probably due to the circulation, because in some instances secondary deposits have been found in the lungs, brain, and in the substance of the liver. The remarkable feature in connexion with malignant embryomata is the complex character of the secondary deposits, for they may contain like the parent tumour hair, glands, hyaline

Most observers are well agreed that the supply of meats f all kinds should be lessened below the proportion ordiarily taken, and some are satisfied merely to reduce r to disallow the red meats (beef and mutton), hile they permit the taking of white and young eats (fish, poultry, veal, &c.) in ordinary quantities. hough the practitioner nearly always is inclined to select hat are called lighter meats, I cannot say that I have bserved any difference of effect on the arterial pressure of he various forms of roast or fried meats—whether as beef, mutton, fish, poultry, &c. A more important difference in this respect seems to me connected with the way in which the meats are cooked—whether roasted and taken with the gravy, or boiled and served without the broth. I therefore make it a rule in these cases to substitute as much as possible boiled for the roasted or fried forms of fish, fowl, beef, mutton, &c.; and to exclude from the dietary meat extractives, such as meat soups, gravies, &c. The proportion of green vegetables and fruits should be increased and carbohydrate foods may be taken in moderation. As a rule I think the cases do best on the reduction of an ordinary diet as a whole, with a diminution of the animal and an increase of the vegetable derived food-stuffs. The reduction of the ingesta to physiological needs and expenditure is particularly important in the management of cases of high arterial pressure; for some such patients who are inactive feel weak and run down and crave for the stimulant effects of tonics and a full meat diet, with excess of salt and other condiments and sometimes of alcoholic drinks.

The question of fluids—their nature, quantity, and best time for their ingestion—is not a matter of indifference. The bulk of the meals should be kept down by reducing the quantity of fluid taken with them. Fluid, of which the best is water, should be taken more freely when the stomach is empty—e.g., a tumbler an hour before meals or night and morning. Preference should always be given to soft or distilled and non-aerated water; or to mildly alkaline waters, as potash and soda salts improve the peripheral circulation; and it is best generally to advise the water to be taken warm. Hard water—i.e., water containing calcium salts in such proportion as to raise the hardness above five degrees—is best avoided, especially in the elderly with a premature rise in the arterial pressure, in whom there may be an inadequate elimination of calcium salts by the bowels and kidneys. Though calcification is generally believed to follow and not to precede degeneration or involution it may turn out that inadequate elimination may lead to the deposition of calcium salts in the arteries, kidneys, and other tissues of the aged[3] As the combination of calcium with an organic acid (e.g., citric) deprives the calcium ion of its specific physiological effect on the blood,[4] the addition of lemon juice to hard water may be a useful corrective in the elderly and gouty.

The question of beverages, such as tea and coffee, is still somewhat unsettled, some observers regarding them as particularly injurious. Long-continued indulgence in strong tea and coffee is, I think, injurious but I see no objection to these beverages in strict moderation, and when their ingestion is not followed by disturbing results, such as palpitation, flushing, giddiness, or wakefulness. As to alcoholic beverages my impression is that high-pressure cases as a class are better without them, but that many cases of moderate or slight increments of pressure may be allowed small quantities without injurious effects, especially if, as a rule, we exclude wines and beer. There is no doubt that when the vaso-motor system is intact alcohol (as in the form of whisky or gin) is vaso-dilator and has but a transitory effect in raising the systolic pressure. The latest experimental work on alcohol (that of Professor W. E. Dixon of Cambridge)[5] shows that in moderate doses alcohol in normal animals and in man may raise the systolic pressure a little (and especially in animals showing signs of circulatory failure) but it may fail to do so, while it diminishes the diastolic pressure ("in other words the difference between the systolic and diastolic pressure tends to increase"), and that it increases the activity and output of the heart, an effect which is ascribed to the fact that alcohol is a readily assimilable food substance.

Chloride of sodium as a constituent of foodstuffs and as a condiment deserves some notice in the treatment of super-normal arterial pressure. The work of Widal and Javal[6] and other continental observers has shown that super-chloridation and superhydration of the tissues take place when the kidneys become impaired in their permeability to the passage of chlorides, as in chronic nephritis and probably in other phases of renal inadequacy not recognised as organic; and that some of the manifestations of Bright's disease (e.g., œdema, albuminuria, &c.) are closely associated with this tissue retention of chlorides and water and are relieved by a dechloriding diet. At present I cannot say from my own observation what is the rôle, if any, which the retention of chlorides plays in the production of the high ranges of arterial pressure which we meet with in chronic interstitial nephritis. Probably it is insignificant. To apply efficiently a dechloriding diet the mere omission of salt as a condiment is insufficient. We must besides this select those articles of food which in the uncooked state contain the least percentage of salt, and omit the addition of salt in their preparation for the table. The diet thus obtained is practically, though not absolutely, chloride-free. Such a saltless diet may consist of vegetable soups (made without meat stock), fresh green vegetables, fruits, nuts, fats (fresh butter, cream), salt-free bread, farinaceous vegetables (potatoes, rice, peas), and sugar. Dufour (in 1905), Guinon and Pater (in 1906), and Déléarde (this year) obtained excellent results from a dietary like this in scarlet fever and scarlatinal nephritis. But in chronic nephritis and in other cases of high arterial pressure such a strict chloride-free diet will scarcely be necessary, though it may perhaps be adopted with advantage for a while now and then when accessions of pressure arise. In fact, a saltless diet soon becomes so distasteful to the majority of patients that it is difficult for them to continue it for more than a week or two at a time. A strict milk diet, sufficient in quantity to maintain the health and condition of the patient—e.g., six pints a day—supplies to the system from 100 to 200 grains of salt (different authorities giving the salt percentage of milk as ranging from 1·6 to 3·0), so that such a diet is by no means saltless. Nevertheless, experience shows that a milk diet or a lacto-farinaceous diet for a few weeks has sometimes an excellent effect on high arterial pressure and on the general health.[7] Unfortunately, milk is often badly borne in these cases, especially when the bowels are inclined to constipation and the liver is inactive; but even then it may often be made to agree by adding to it citrate of soda or potash, or when there is gastric acidity sodii bicarbonas or liquor magnesii carbonatis. But a lacto-vegetarian diet is more suitable in most cases; a moderate daily quantity of milk (e.g., two or three pints) when taken with vegetable foodstuffs (bread, rice, green vegetables, and fruits) should not seriously raise the low percentage of ingested salt and, moreover, it advantageously increases the proportions of the proteid and fat, especially when combined also with cream, cheese, and eggs. Cheese in moderation is perhaps the least objectionable form of proteid food in these cases. Meats of all kinds contain even a smaller percentage of native chloride than that of milk; but the cardio-vascular stimulant effect of the extractives which they contain more than counterbalances any advantage they possess in their relatively low percentage of salt. Boiled meats, however, containing less salt and extractives than roast meat may be added to the dietary without disturbing its comparatively salt-free character. Fresh-water fish (such as trout, tench, pike, and crayfish), which contain much less salt than salt-water fish, may also be taken if we do not require to adhere to a strict minimum supply of ingested salt. The condiments—pepper, mustard, vinegar, lemon, &c.—none of which are contra-indicated, are useful in relieving the insipidity of the dechloriding diet.

---

[3] An interesting communication, The Part Played by the Calcium Salts in the Blood and Tissues, appears in the British Medical Journal of April 27th, 1907, in which Dr. W. Blair Bell refers to three calcium physiological periods. "The third period is that of late life, when no calcium salts are required for the building up processes or for those of reproduction. These salts then accumulate in the tissues, especially in the vessels —— atrophy occurs, and the individual gradually declines."

[6] Journal of Physiology, March, 1907. La Cure de Déchloruration, par le Dr. Fernand Widal et le Dr. Adolphe Javal, Paris, 1906.

[7] See an address on Arterio-sclerosis by Dr. W. P. Herringham, Brit. Med. Jour., vol. i., 1907, p. 61. According to the recent experiments of C. J. Coleman, milk as a diet does not appear to increase the coagulability of the blood, as much of its calcium content is not available as a factor in controlling the coagulation, for it is probably combined with organic (and not mineral) acids, which combination does not shorten the coagulation time. (The Bio-Chemical Journal, op. cit.) So it is not improbable that if calcium favours a rise of arterial pressure (vide sup.) milk may fail to do so, just as it fails to increase the coagulability of the blood.

detected another entirely separate collection of pus, most putrid in smell, some ounces in all, which lay between the rectum behind, the bladder in front, and the left wall of the pelvis laterally; this is what I refer to as a "par-appendical" abscess. The pelvis was drained by a Mikulicz gauze bag and the greater portion of the wound was sutured. The interval which has elapsed since the operation has passed satisfactorily, the general abdominal cavity has remained free from infection, the temperature is normal, the pulse is 80, the urine is free from smell and practically is free from pus, and the symptoms of frequent and painful micturition have disappeared.

Clearly the cystitis arose by infection from the abscess on the left side of the pelvis, not by the pus bursting into the viscus but apparently by continuity of tissue. In several hundred cases of appendicitis I have only once before seen this complication. The patient, a girl, aged 12 years, had been ill with appendicitis for two months and when transferred to my care was suffering from cystitis and an abscess in the pelvis. In this patient again the cystoscope failed to show any direct communication between the abscess and the bladder; the infection of the latter appeared to have arisen merely by the contiguity of the collection of pus. Thorough evacuation and drainage of the abscess cured the cystitis without any additional measures. Rare as is cystitis, pelvic appendicitis, on the other hand, is quite a common condition and not infrequently is overlooked. At the onset we find the symptoms which generally indicate appendicitis—pain *experienced* about the *central* area of the abdomen, vomiting, quick *pulse*, *elevation of temperature*; *local* tenderness, rigidity, or perhaps tumour in the right iliac fossa are absent, but the tenderness is found if looked *for* over the pelvic area. Constipation, so generally present in appendicitis, is *often* absent and diarrhœa takes its place; in addition, rectal tenesmus with small discharges of watery mucus at frequent intervals is complained of in some cases, difficulty in micturition also arises and pain after the act is then generally present, and occasionally retention of urine occurs. When symptoms suggestive of appendicitis arise and the local phenomena in the right iliac fossa are absent, examination by the finger in the rectum will often recognise an inflammatory swelling which explains the nature of the attack. The anterior wall of the bowel is found swollen, œdematous, and infiltrated; there may be a well-marked mass occupying a good deal of the pelvis, capable of being palpated bi-manually. A softened, almost fluctuating, area may be detected in this, indicating a collection of pus just adjacent and suggesting an easy route for its evacuation; or, on the other hand, as in the patient under consideration, if the case is a chronic one the mass felt may be tough and dense to a degree quite precluding any attempt at opening through the rectum and requiring for its removal the opening of the abdomen.

Par-appendical suppuration is uncommon but can hardly be described as rare. It appears to arise in this way: the inflammatory attack starting in the appendix involves a considerable area of the peritoneal cavity, most often the pelvic cavity and parts adjacent. The patient struggles on, part of the sero-purulent fluid is absorbed and localised pockets of pus well circumscribed by adhesions are left; the infection remains alive but does not spread. One of these pockets of pus is usually but not always found around the adherent appendix, the other or others at some distance, but commonly in the pelvic cavity. Whilst this man whose case I have taken for my text has been in the ward a little child has been admitted with a similar condition. Three months ago the abdomen was opened and pus was let out, but the cause of the abscess does not appear to have been determined. Since that operation three acute abdominal attacks have occurred and three days ago I re-opened the abdomen to find the appendix in the pelvis, perforated at its base and with a small abscess around it, whilst to the left of the middle line of the pelvis another much larger collection of pus was found quite shut off from that around the appendix. Examples such as this could be multiplied, but enough has probably been said to indicate to you the importance of these cases of pelvic appendicitis and the ease with which they may be recognised if proper investigation is made.

THE RED CROSS CONFERENCE.—It is announced that the King and Queen will receive the delegates to the International Red Cross Conference at Buckingham Palace on Saturday, June 15th. Levée dress will be worn at the reception.

SOME NOTES ON THE CONTROL OF SUPER-NORMAL ARTERIAL PRESSURE.[1]

BY GEORGE OLIVER, M.D. LOND., F.R.C.P. LOND.

I PROPOSE to submit for your consideration and discussion some of the conclusions respecting the treatment of super-normal arterial pressure, to which I have been led more particularly during the past few years. In doing so I cannot, however, hope to add much to your practical knowledge or to what has been already done by other workers; nevertheless, I trust these notes, which are the outcome of a large amount of observation in a field particularly well adapted to the clinical study of arterial pressure, may contain some suggestions which you may turn to good account in practice. We should keep in mind that though variations of the arterial pressure may produce certain pathological effects they themselves are but results. When, for example, the arterial pressure is raised but *temporarily* the *cause* may be, and, in fact, usually is, of nervous origin—either psychical or reflected; but when the pressure rise is persistent it may be regarded as the outcome generally of some alteration in the chemical composition of the plasma or of organic changes in the circulatory mechanism, which may or may not have themselves resulted from some bio-chemical cause. It follows, therefore, that in attempting to control a persistent rise in the arterial pressure we should if possible learn what are the etiological factors at work. *Unfortunately*, at present our knowledge in this direction is extremely limited and we must content ourselves with treatment on general lines, with the application of such practical suggestions as may be derived from physiology, which is, after all, the mother of medicine.

The method of observation followed.—I have employed the clinical fluid manometric method which was brought forward some years ago by Roy, Leonard Hill, and Riva Rocci, using more particularly the hæmomanometer which I described two years ago. I did not then realise that Leonard Hill was the first to apply the ordinary manometric *device* of fluid pressure on *both* ends of the index of a sphygmometer, as shown by the specification of his instrument patented in 1898 and recently brought under my notice, but not hitherto placed on the market. Having thus unwittingly devised the same mechanical arrangement, my instrument, though possessing certain distinctive features, will not be produced in its original form. I show you the model of an instrument on which I am now working. In it there is a simple combination of mechanical details not hitherto employed—so far as I know—which secures certain advantages; such as the impossibility of leakage (the apparatus being valveless) and the attainment of increased precision in reading the systolic and diastolic pressures. I also show you the hæmodynamometer, the pocket blood-pressure gauge which I introduced nearly ten years ago. With this instrument most of my earlier observations were made and I still find it convenient and accurate in clinical work. The pressure readings it affords are quickly made, without entailing discomfort to the patient or causing local or general disturbance of the circulation. It is therefore time-saving and is preferred by sensitive patients, who frequently resent circular compression of the arm, or even of the forearm, especially when high readings are necessitated by the arterial pressure. I have lately improved this instrument so that it now furnishes the systolic as well as the diastolic pressure.

Dietary treatment.—When the arterial pressure is raised the principal aim in our dietetic directions should be to select a diet which has the least stimulating effect on the circulatory organs. Hence we should reduce as much as possible not only the bulk of each meal but also the proportion of those constituents of the foodstuffs which more particularly stimulate the cardio-vascular apparatus, such as various salts, soluble extractives, active principles and other bodies (e g., alcohol), which are directly absorbed without change and may be regarded as exogenous hormones between the digestive tract and the circulatory apparatus, stimulating the heart on the one hand and the capillary circulation on the other.[2]

---

[1] The substance of this paper was read at a meeting of the Therapeutical Society on April 16th, 1907.

[2] See some good illustrations of the value of this teaching in a recent paper by Dr William Russell, Brit. Med. Jour., vol. i., 1906.

temperature. But when the water contains or is charged with certain chemicals (such as chlorides, sulphides, extract of pine, peat, and carbonic acid) the lowering effect on the arterial pressure is prolonged. Hence the calmative influence of peat, sulphur, pine, saline, and carbonic acid baths followed by dry, warm packing on the circulatory organs and the nervous system, and their adaptability to the treatment of those cases of increased arterial pressure associated with some phase of nervous irritability, or with contraction of the cutaneous blood-supply and some inefficiency of the skin as an emunctory organ. A course of such bathing will produce good results, even when the arterial pressure is moderately increased. But I rarely find it desirable to rely upon these still baths entirely, for they are apt to leave the muscular system relaxed and toneless. They are more valuable as intercurrent baths in a course of massage bathing which exerts a more decided effect in lowering the arterial pressure while maintaining or even improving the nutrition and tone of the muscles. Warm massage douching, exemplified by the Aix-les-Bains douche followed by the needle bath of alternating temperature and warm pack, is, according to my observation, one of our most valuable balneological procedures for treating cases of super-normal arterial pressure. In it we have in synergic combination the action of warmth, massage, and vibration in diverting the blood to the peripheral vessels of the richly endowed vascular area of the muscles as well as that of the skin.

Electrical treatment.—D'Arsonvalisation. I have been occasionally struck with the beneficial effect of the D'Arsonval current—merely the general effect for 20 minutes daily. Bipolar massage with this current or the sparking application of it to the limbs and body is also now and then useful in addition. Dr. Montier has adduced some striking evidence[11] in support of the reducing effect of D'Arsonvalisation in hypertension, he having, for example, observed in some cases, even after a few séances only, a fall from such high readings as 220 or 230 mm. Hg to 150 or 160 —a fall which was, moreover, remarkably persistent notwithstanding the discontinuance of further electric treatment. I have not myself observed such encouraging results but my observations have shown that D'Arsonvalisation is often, and especially in elderly subjects, a valuable adjunct to other treatment (dietetic and balneological). Electric light and ozone baths, which secure active cutaneous elimination at a comparatively low temperature, have also proved useful in many of my cases. I have not seen any specially encouraging results in these cases from other forms of electric treatment, such as electric immersion baths (faradic or galvanic).

Care of the skin.—It is important in these cases to maintain the cutaneous circulation at its optimum efficiency. Warmth diverts to the skin a comparatively large volume of blood and this lowers the arterial pressure; hence the value of warm efficient woollen clothing and of warm equable climates (such as those of Jamaica, India, or Egypt) during our winter and spring months. Cold and especially cold windy climates are most injurious in high pressure cases. Cutaneous elimination should be encouraged; a thorough perspiration should be obtained once or twice a week by means of a lamp bath (home Turkish bath) or an incandescent light bath or a Turkish bath, followed by efficient massage and removal of effete epithelium. By active perspiration the plasma and tissue-fluids are relieved of an excess of sodium chloride and metabolic residua.

Venesection.—So far I have had no experience of venesection in the ordinary course of treatment of high-pressure cases, apart from the actual accidents of uræmia and cerebral hæmorrhage. Now that we have in the clinical manometer an instrument of precision to guide us in selecting the right case for venesection, should we not avail ourselves more often than we do of the rapid hypotensive effect of this measure when suspiciously threatening symptoms arise, or when in certain plethoric subjects a very high pressure does not respond sufficiently to the ordinary preventive measures, especially if the free use of vaso-dilators is not effectual? Under such conditions many years ago I used to apply Junod's boot, which acts like a magnified cupping glass, with apparently favourable results, but I think a limited venesection would be still more effectual than this. The apparatus consists of (1) a metal boot sufficiently large to accommodate the leg up to the thigh where the opening is rendered airtight by a broad band of india-rubber, and (2) an air-pump attached to a nozzle communicating with the interior of the boot through which the air within is rarefied.

Medicinal treatment.—Sometimes dietetic treatment, regulation of rest and exercise, and some balneological procedure—such as thermo-massage—will suffice to correct the increment of arterial pressure, more especially in its slighter degrees. But in most cases it will be found that some medicinal treatment or other in addition will be either useful in expediting the progress or will be necessary. That treatment may be directed into one or other of the following lines—namely (1) to secure (*a*) free evacuation and correction of the liver and bowels and (*b*) gastro-intestinal antisepsis; and (2) vaso-dilatation and sedation of the vasomotor nervous system.

I. *Evacuant and antiseptic treatment.*—There is no doubt that all forms of super-normal arterial pressure are benefited less or more by purgatives; not so much, however, by the occasional aperient dose as by a daily increased discharge from the bowels. The benefit thus derived may be ascribed to (1) the stimulation and correction of the liver and other abdominal glands; (2) the daily baling out through the intestinal mucous membrane of salt[12] and water from the blood and the tissues with stimulation of the intermediary circulation; and (3) the removal of intestinal toxins. To be efficient the aperient must produce a free watery discharge. Saline purgatives should be taken in hot water in the early morning, such as sodii sulphas or soda tartarata or sodii sulphas with magnesii sulphas, and in addition there should be an occasional mercurial dose—e.g., once or twice a week (calomel or pilula hydrargyri) at bedtime. Just now we regard the generation of toxins in the gastro-intestinal area (chronic intestinal auto-intoxication) as the possible, if not probable, cause of several ailments of obscure origin, such as gout, arterio-sclerosis, &c. Metchnikoff has shown us the importance of avoiding the ingestion of bacteria in raw fruit and vegetables by heating and cooking them. But cooking is objectionable in depriving certain raw fruits and vegetables of their delicate and appetising flavour. In the case of grapes, salads, and perhaps strawberries, we may, however, render them aseptic without impairing their natural flavour by dissolving one of Dr. Rideal's tablets of bisulphate of soda in ten ounces of water and using this as a wash water. Intestinal antiseptics are often useful when the arterial pressure is persistently raised, such as benzo-naphthol, salol, salacetol, and tylmarin (acetylated ortho-coumaric acid), which tend to ease the peripheral circulation like the other members of the aromatic series. Mercurials are also not only antiseptic but relax the arterial wall, and I have observed that parvule doses of calomel (tabloids of one-tenth grain) twice or three times a day may be taken for a few weeks now and then with a favourable effect on the arterial pressure. The red oxide of mercury tabloids ($\frac{1}{10}$th grain) are also worthy of a trial. Small daily doses of sulphur—such as the compound sulphur or the guaiacum and sulphur tabloids—are not only useful as laxatives but in favouring a fall of the arterial pressure.

II. *Apressor remedies.*—Arterial pressure may be reduced either by diminishing the output of the ventricle or by widening the bed of the whole arterial system and especially its peripheral portion. Experience shows that it is futile, if not injurious, to attempt to obtain a depressor effect and to maintain it by drugs, which lower the action of the heart. Just lately Coley of Philadelphia, for example, has show that such drugs as aconite, veratrin, antimony, and chloral, are unsatisfactory and scarcely justifiable remedies for the purpose of reducing the arterial pressure.[13] Our choice of apressor remedies is therefore restricted to those which favour dilatation of the calibre of the arteries and thus ease the flow of blood through the distal portion of the circulation. Their physiological action on the arterial pressure (distal and proximal) is easily demonstrated by the manometer in man by administering a dose of nitro-glycerine; and I have elsewhere shown how useful it is in the course of clinical observation thus to gauge the vaso-dilator response of the arteries.[14]

Desideratum in an apressor remedy.—Control of a persistently high arterial pressure by drugs is less or more

[14] Studies in Blood-Pressure, p. 92.

When the systolic arterial pressure maintains a high range (e.g., over 220 millimetres) this dietary should be tried, and especially when there are albuminuria and any œdema, however slight. But even when the arterial pressure is equally high and there is not even the merest trace of albumin in a pellucid urine, we may still entertain a suspicion of kidney insufficiency—such as may diminish the permeability of the chlorides, even though it may not appreciably affect that of the urea; and we may find a trial of the dechloriding diet as useful in such cases as in the albuminuric ones. When the kidneys are sound and normally permeable to sodium chloride it is not likely that the ordinary use of salt will interfere with the eliminatory work of the kidneys or will raise the arterial pressure, except quite temporarily, for normal renal elimination of the chloride is too rapid to allow of a permanent rise in the percentage of it to take place in the plasma and tissue fluids. We may therefore infer that if there is a permanent retention of chlorides it will be invariably pathological and not a physiological condition, and our aim and treatment is to restore the chloride equilibrium by reducing the amount of the ingested chloride to that which is eliminated by the kidneys. The question, therefore, is one of renal inadequacy in the elimination of the chlorides.

Should the arterial pressure be permanently raised without there being any failure in the elimination of chlorides, urea, and the xanthin bases the reduction of ingested salt is not likely to lower the arterial pressure, though it is well to test the matter by observation. In one such case I observed that the pressure actually rose on reducing the salt and diminished on allowing the free use of it; in the former case, after correcting for the renal elimination of the different amounts of the ingested chloride, the total daily urinary solids diminished and in the latter increased; and this observation was verified by repetition. May it not be that salt in the normal state of the kidney favours the elimination of nitrogenous waste products, which are less freely excreted when the renal permeability to chloride of sodium fails?

I have observed that as we grow older (say over 65 years or so) there is apt to arise a tendency to indulge more and more in the use of salt. When the arterial pressure rises unduly in elderly subjects we should do well to look out for this disposition. The suggestion of the late Sir W. Roberts, that we should substitute chloride of potassium for chloride of sodium as a table salt, is supported by Bunge,[8] who has shown that when potassium is ingested in excess of sodium a loss of the latter from the system takes place. Unfortunately, chloride of potassium is by many disliked as a table salt, but it is less objectionable when combined with 50 per cent. of chloride of sodium, and I have found the following a useful formula in high-pressure cases: Lithium benzoate, 1 drachm; or potassium benzoate, 3 drachms; potassium chloride, 2 ounces; sodium chloride, 1 ounce: a half-drachm measureful to be used.

Tobacco smoking is sometimes looked on as a questionable habit when the arterial pressure is increased, and knowing that nicotine raises that pressure and will even produce something like arterio-sclerosis in animals we may be disposed to look on smoking with suspicion. But smoking does not necessarily imply the absorption of all the nicotine contained in tobacco, as when, for example, the weed is chewed. For combustion breaks up the nicotine into such products as pyridin, carbon monoxide,[9] &c., which predominate in the smoke, though this may also contain a little nicotine. Hence the physiological effects of smoking on the arterial pressure will be due to the combined action of all the products of combustion as well as those portions of nicotine which escape destruction and which may be directly absorbed from the end of a cigarette or cigar. From the observations which I have made on myself and other normal subjects not habituated to smoking I find that it always raises the systolic pressure (e.g., from 10 to 20 mm. Hg.) without producing a corresponding rise in the diastolic pressure; in fact, the latter pressure will generally either remain unaltered or may even fall, the pulse pressure range (i.e., the difference between the minimum and maximum pressures) being increased. The effect, as a rule, passes off quite quickly, generally in ten minutes or so; but notwithstanding this fact it is undesirable in the management of cases of super-normal arterial pressure to permit indulgence in a habit which raises the systolic arterial pressure. Besides Barazzoni found that in subjects with high tension pulses the rise of the tension produced by tobacco smoking is more exaggerated than in subjects with low or medium tension and leads to dyspnœa, palpitation, præcordial distress, vertigo, tremors,[10] &c. In most cases when the habit of smoking can be given up it is best to encourage the patient to do so; and abstinence can generally be easily enforced in those who have been light or occasional smokers or who experience slight palpitation, hea hurry, anginal pain, or other discomfort after smoking. B in the habitual smoker it is not always easy even to limit t indulgence, though we should endeavour to do this whenev possible.

Rest and exercise.—The value of absolute rest in t management of high-pressure cases should be emphasised for I doubt if we all quite realise it as fully as we ought t do. We not infrequently see its calmative influence on t arterial pressure of bed cases (as in hospital), the pressu readings in similar pathological conditions being generall lower in them than in patients leading their ordinary live Absolute rest is the best sedative of exalted ventricul action, that large factor in maintaining super-normal pre sure, especially in the higher ranges; and this is oft apparent even when the response of the peripheral arterie to a vaso-dilator is either greatly limited or is not apparent In many such cases increments of pressure recur fro cardiac excitation induced reflexly or bio-chemically, whe recumbency for varying periods is invaluable, even thoug the heart muscle may not show signs of actual failure. Th periods of absolute rest required may vary from a day once or twice a week to even three or four weeks at a time; an after the lapse of the longer intervals of resting, care should be taken to see that the assumption of the accustomed exercise is gradual, or the good effects of the recumbency may be nullified.

When the arterial pressure rises beyond a certain moderate degree the patient is apt to become somewhat lethargic and inactive. We should in such cases encourage the taking of as much regular, moderate, and equable exercise as the patient's limit will safely permit. Walking is the best of all exercises, but, unfortunately, even when indulged in quite moderately, these patients frequently complain of early "fagging." Then in suitable cases gentle cycling on roads of low gradients and with a low-geared cycle is preferable, or horse riding, a form of exercise which we are apt to overlook in this mechanical age. All sudden forms of exertion should be avoided, such as straining at stool, &c. But the prescription of exercise when there is a rising pressure in the elderly requires some discrimination and caution. Many men over 60 years of age, who have led sedentary lives, on retiring from business are apt to adopt the ways and games of young men, and being unconscious of the fact that they have already used up much of their endowment of rubber in their arteries are apt to come to grief in cardio-vascular breakdown. Such cases are an object lesson to us to preach moderation in physical exercise to the elderly in whom we detect signs of diminished elasticity and play in the vascular walls, so that they may be induced to economise their remnant of rubber. Still, on the other hand, moderate activity in the elderly is generally beneficial; hence a sudden retirement from active business often leads to a premature break-up. The cardiovascular stimulation of exercise should always be avoided just after a meal. The patient should then rest recumbent or semi-recumbent for a good part of an hour; and after that interval has elapsed he should always take exercise however limited it may be. Special exercises, such as tension exercises, and graduated resistance and slow deep breathing exercises, are often valuable in widening the peripheral vessels and in letting down the arterial pressure; and massage is useful when the heart begins to weaken.

Balneological treatment.—Some experience in the use of different kinds of baths in the treatment of these cases has clearly indicated that some balneological procedures are more potent than others in relieving super-normal arterial pressure. But in the few words which can here be devoted to the subject of baths I can only indicate the general drift of that experience. Immersion in warm fresh water lowers the arterial pressure, chiefly by relaxing the cutaneous and splanchnic arterioles; but this effect is quite transitory and the cutaneous circulation is left more amenable than before the immersion to the contracting influence of a lower ich resist appreciable modification by treatment. But ese conclusions are only such as might have been ticipated, for a high percentage (probably about 90) of the ses presenting systolic pressure of over 200 millimetres are ses of chronic nephritis or of diffuse arterio-sclerosis—with without renal implication; and in a large proportion of ose in which the pressures are below 200 millimetres the se is, as a rule, the outcome of conditions less or more mediable. The percentage of cases regarded as amenable treatment will also be considerably influenced by the actitioner's conception as to whether the pressure is normal super-normal in any particular case, as there being no ich narrow line as that of the normal temperature each bserver, though knowing the general range of the normal ressure, gradually builds up from his experience a correction r individual instances, being mainly guided in this by the ollateral signs and symptoms and by the effects of treatment borderland cases. When, for example, he discovers that systolic arterial pressure of 145 or 150 millimetres, which e regarded as doubtfully normal, may be reduced to, say, 25 or so, with an improvement all round in the patient's ondition and health, he will conclude that the latter and ot the higher pressure is the patient's normal reading. Such xperience is likewise useful in showing that we can thus ick out cases still amenable to treatment which might therwise be allowed to drift into the less controllable nd higher ranges of super-normal pressure. Our clinical management of blood pressure thus becomes more preventive. It seems to me, therefore, desirable to subject most cases in he doubtful area (from 145 to 160 millimetres) to corrective reatment before accepting from 145 to 150 millimetres in a routine way as the parting line between the physiological and pathological areas.

An increment of the arterial pressure is a result.—Finally, I wish again to emphasise the fact that super-normal arterial pressure is not itself a primary condition to be attacked or controlled as such. It is invariably a result of some pathological cause or causes, and it is, moreover, often indeed a necessary result of conditions which we cannot remove. While realising what are the ill effects of high arterial pressure and trying to modify them as best we may by our attempts to moderate the pressure, we are apt to forget that that pressure is not infrequently a necessary evil and should sometimes be regarded as a compensatory effort or as one of the natural defences of the body. On this point Dr. Theodore C. Janeway, who has done so much to advance the clinical study of blood pressure, has recently remarked, after referring to the futility of drugs to keep down the blood pressure, "Another common experience is that the steady downward progress with falling blood pressure, when heart weakness supervenes, is often made worse by arterial dilators. If improvement comes under digitalis, for instance, the pressure usually rises. These observations find their readiest explanation, if we believe that for such patients an average level of arterial pressure far above the normal is absolutely necessary to insure the requisite speed of capillary blood flow. For them the optimum pressure for the maintenance of a normal circulation may become 200 mm. or more, instead of 100 to 145 mm. ...... Where no symptoms of a threatening nature exist these preventive measures alone are called for. Under such circumstances a systolic blood pressure of 200 mm.—yes, even 250 mm. and over—is not incompatible with a number of years of comparative comfort and activity, particularly if the response to treatment is favourable and the patient coöperates heartily."[22]

Farnham.

[22] Some Common Misconceptions in the Pathological Physiology of the Circulation and Their Practical Significance, by Theodore C. Janeway, M.D., New York Medical Journal, Feb. 2nd, 1907.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—The thirty-first annual meeting of the above association was held at 20, Hanover-square, London, W., on May 7th. The report gave the number of members as 624 and of student associates 350. During the year the Scotch and Irish branches had been dissolved and 11 new branches formed in provincial centres with medical schools—namely, Belfast, Bristol, Cardiff, Dublin, Dundee, Edinburgh, Glasgow, Leeds, Liverpool, Manchester, and Newcastle-on-Tyne. Others were about to be formed and it was expected that the members in these localities would do good work among the medical students. After refreshments Professor G. Sims Woodhead, the President, gave an address on the Medical Justification of Total Abstinence.

A CASE OF CHLOROMA.

BY FRANK M. POPE, M.D. CANTAB., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO THE LEICESTER INFIRMARY.

With Microscopical and Pathological Notes by WILLIAM E. REYNOLDS, M.B., CH.B. Edin., *House Physician to the Infirmary.*

THE following case is one of such rarity and deep interest that it seemed worthy of publication.

The patient, a boy, aged 14 years, was admitted into the Leicester Infirmary under the care of Dr. Pope on Feb. 13th, 1907, complaining of pallor, swelling of the eyes, shortness of breath, and weakness. He gave the following history. Two months before admission the patient noticed that he was easily tired and unfit for work. At this time he was getting paler and was suffering from a bad cough. Two weeks later he noticed hæmorrhagic patches on his legs which had come on without any apparent cause or injury. These were described as small, painless, and having a purple colour. A few days later they appeared all over his body but not many at a time. There had been no epistaxis or bleeding from the gums. Three weeks before admission he became aware that his eyes were swollen; this was more noticeable in the morning. He kept at his work until a fortnight before admission. For the last ten days he had to remain in bed. Two or three days before admission he noticed "bruises" on his face and legs; these were present on admission. He never suffered any pain during his illness but steadily became weaker and paler. The bowels were constipated. The only fact worthy of notice regarding his previous health is that he dislocated the left elbow on August 7th, 1906. He was treated in the casualty department of the Leicester Infirmary, recovery being uneventful. He had eight brothers who up to the time of his admission were quite healthy and with no history of any disease.

On admission he presented a pronounced waxy colour, looked very ill, and was considerably emaciated. There were marked puffiness of the eyelids and slight proptosis. The conjunctivæ were chemotic and pale; there was also some subconjunctival ecchymosis, most marked beneath the upper lid of the right eye. A few spots which had the appearance of pustules were present over the bridge of the nose, left eyebrow, forehead, and right side of the chin; they contained what seemed to be yellow pus; their bases were œdematous and of a dull greyish colour but were not painful or tender to touch. There was a glandular enlargement of slight degree involving the cervical glands—both superficial and deep groups—the axillary, inguinal, and femoral glands. General development was good. The respirations were 24 per minute and normal in character. He had a frequent hacking cough but no expectoration. The temperature was 103° F. He complained of great thirst, was constantly calling for water, but refused all nourishment. The bowels were usually constipated. The mouth was very dry and the teeth, gums, and inner surfaces of the lips were covered with thick brown crusts. The mucous membrane was pale; there were no hæmorrhages; the gums were not spongy and did not bleed readily. The tonsils were not enlarged. His abdomen moved freely with respiration, no distension or ascites being present. The liver was not enlarged; its lower edge was just at the costal margin in the right mammary line. The spleen was easily palpable and extended two inches below the costal margin; it was slightly tender on palpation; on percussion its upper limit was found to extend to the eighth interspace, half-way between the posterior axillary line and the scapular line; its posterior limit appeared to be about an inch from the vertebral spines. He was slightly dyspnœic on exertion; the pulse numbered 104 beats per minute and was regular and soft. The heart's apex beat was visible, diffuse, and felt in the fifth space a quarter of an inch external to the left mammary line. On percussion the deep cardiac dulness was as follows: the upper border was at the third left rib, the right border was at the lateral sternal line. At the mitral area there was a soft systolic murmur propagated for three inches into the axilla; the second sound was faintly heard but clear. At the aortic area the sounds were faint and no murmur could be detected. Both sides of the chest moved freely on respiration. The percussion note was impaired over the right base at the back where the breath sounds were broncho-vesicular in type. Over the left lung at the unsatisfactory. Should an impression be made there is the gradual failure to maintain it, or the great liability—often, indeed, the certainty—of the recurrence of the higher pressure on discontinuing the remedy or on reducing the dose of it. The effect is, indeed, rarely curative. The desideratum in an apressor remedy seems to be the discovery of some agent which will modify arterial pressure on the lines followed by nature—some product or other which may be continued without harm so long as it may be required. We may as experimental work proceeds find the solution of this question in physiological chemistry, and we are already beginning to realise that arterial pressure may be the resultant of the interaction of pressor and apressor products supplied to the blood by the internal secretions of the various organs and tissues and that the higher ranges of pressure we meet with may arise from the predominance of the pressor products, the antibodies being generated in insufficient quantity.

The depressor effect of ingested thyroid.—We know that the adrenal and the pituitary glands and the kidneys yield pressor bodies; but our knowledge of apressor products is much more limited—the internal secretion of the thyroid gland being about the only one with an experimentally proved depressor action. I have observed that the ingestion of thyroid gland increases the calibre of the arteries and lowers the arterial pressure, and in many cases of increased arterial pressure it is undoubtedly useful, especially in subjects over 45 or 50 years of age of a gouty or obese type, but it is not a remedy which should be prescribed in a routine way in the majority of cases. When given in guarded dose with each meal it will often modify the pressure and improve the general health, and then it may with occasional supervision be safely continued with advantage for long periods. It has been thought by some (Stockman, Rolleston)[15] that the iodides exert their beneficial effect on arterio-sclerosis and heightened arterial pressure by stimulating the thyroid; they do not, however, reduce the arterial pressure. And just lately Chalmers Watson[16] suggests that the good results obtained from a bread-and-milk diet observed by Herringham[17] in certain cases of arterio-sclerosis with increments of arterial pressure arise from the profound influence of a diet in which milk largely preponderates on the structure of the thyroid gland which he has demonstrated in animals—this therapeutic effect being according to him "indirect, the thyroid gland spontaneously recovering under the influence of lessened strain on its functional activity."

The depressor effect of some other normal constituents of the plasma.—But I think we may question whether the internal secretion of the thyroid is the only apressor agent present in the plasma, notwithstanding its obvious importance. Is it not probable that the arterial pressure is normally modified by some of the saline constituents, some tending to raise the pressure, while others lower it in proportion to their preponderance? The quantitative relation between the various salts of the serum is probably maintained within certain limits in health, and in disease that relation may at times be disturbed either by the undue ingestion or the defective elimination of certain salts (such as calcium carbonate and sodium chloride). Somewhat cognate physiological facts point to the important influence of the salts of the plasma. Ringer has shown that the salts of calcium, sodium, and potassium must exist in an ideal circulating fluid in the right proportion and those of calcium are of singular importance in maintaining the contractility of the ventricle, and Waller has demonstrated that potassium depresses and calcium augments the variations of electric response in nerve. Moreover, we also know the important rôle played by calcium in the coagulation of blood and milk. May not a similar relationship subsist between the various salts of the plasma and the blood pressure? In man the depressor effects of the potassium salts, whether as carbonate or citrate, on the arterial pressure are often more striking than might be expected from the results of experimental work; and the maintenance of a lower level of pressure thus obtained may be partly due to the corrective effect of the ingested alkaline salts on the disturbed balance produced by the predominance of pressor salts. In practice we frequently combine the nitrates and nitrites with the carbonates or citrates of potassium. Sir Lauder Brunton associates nitrate of potash (20 grains) and nitrite of sodium (from a half to two grains) with this alkaline treatment (potassium bicarbonate) in a large tumbler of water in the early morning; and I have observed excellent results from a continuance of this prescription in many cases of decided super-normal pressure. Alkalies are generally well borne by such cases for long periods. But my observations in man dispose me to conclude that there may be other salts normally present in the plasma which tend to lower the arterial pressure, such as the hippurates and benzoates. I have given these salts a good clinical trial during the past two years or so and I am satisfied that they are useful in cases of hypertension and of moderate increments of arterial pressure. As a rule they improve the general health and well-being and are well adapted for long-continued use in the preventive treatment. In many cases of hypertension, especially in women and overworked anxious men, I have observed that the association of *ammonium bromide* with ammonium hippurate or benzoate is still more beneficial in providing a higher degree of sedation of the vaso-motor nervous system than is furnished by either remedy alone. There are also other remedies furnishing hippuric acid to the system which are worthy of trial in cases of super-normal arterial pressure, such as quinic acid, styracol, tylmarin, which are obtainable in the tablet form. It is interesting to find how many remedies with a benzene nucleus are useful in gout as well as in arterial hypertension.

Exogenous apressor remedies.—I shall not discuss the important therapeutic range of the *nitrites*, for this is well established and common knowledge. *Iodine* as KI, &c., has for many years been relied on as our sheet-anchor in the treatment of cases of arterio-sclerosis, whether it is associated or no with a rise in the arterial pressure. In such cases the iodides are surprisingly well borne in large doses by the mouth without producing symptoms of iodism or of depression, but my manometric observations show that they have no direct effect on the arterial pressure, and therefore they agree with those of Stockman, Burnet,[18] Janeway, and some other observers. But notwithstanding this fact, I have often found a long continuance of the iodides in small doses most useful in cases of super-normal arterial pressure. *Citric acid and the citrates* have been employed to reduce the coagulability of the blood by decalcifying it[19] and I believe they have also been prescribed as apressor remedies. The use of the *salts of magnesium* (e.g., magnesii citras or chloridum) is also suggested as decalcifying agents by the work of Dr. J. Malcolm, who has shown that the ingestion of the soluble magnesium salts causes a loss of calcium in adult animals and hinders its deposition in young growing animals.[20] These salts may therefore prove useful in the senile who are prone to calcium deposition with increment of arterial pressure. *Sparteine* has recently been suggested by Professor Dixon of Cambridge[21] for lowering the arterial pressure; but I have not as yet made any clinical observations with it, as I hope to do.

The amenability of increased arterial pressure to control.—Cases present decided differences in their response to treatment. This disparity is doubtless largely due to variations in the cause and in the stage of development of the pathological condition. The effects of treatment also differ considerably in the two classes of cases—namely, in the cases in which we can freely prescribe rest and regulation of exercise and life generally and in those who must follow their avocations and their ordinary routine. In the former class the results are often more satisfactory, even when the pressure runs into the higher ranges. But the fact remains that the pressure is much more amenable to control in some cases than in others in which it may be, and not infrequently is, practically uncontrollable. My observations lead me to the general conclusions—to which, however, I have met with some exceptions—that there is an inverse ratio between the observed reaction to vaso-dilatation and the degree of persistent super-normal pressure; and that in cases following their ordinary course of life the amenability of the pressure to be controlled by treatment diminishes in a general way in proportion to the rise of pressure—the cases having persistent systolic pressures of over 200 mm. Hg furnishing by far the majority of those pigmentary change. The stomach was pale lemon yellow and showed numerous green patches below the mucosa. The lymphatic glands of the upper part of the duodenum and the stomach were green and hyperplastic; those of the large and small bowel and the axillary and inguinal glands were only hyperplastic. The thoracic duct and mediastinal glands were the seat of the most extensive growth; in places it extended over the bodies of the vertebræ, below the parietal pleura along the costal surfaces. The bone marrow was of normal colour. The orbits were distended with hard greenish tissue, replacing most of their softer contents, in parts showing a tendency to deep-seated caseation. The condition of the temporal fossa, especially on the right side, was a marked infiltration of the muscle by the green growth. Flat masses of green growth were also numerous below the cranial periosteum, between the dura mater and the bone, and along the superior longitudinal sinus. Small punctiform hæmorrhages were seen below the serous surface of the dura mater. The choroid plexus showed some pigmentary change but no definite growth could be detected. There was no thrombosis of the sinuses. All the green tissues after a few minutes' exposure to the air became paler in colour. Cultures taken from the spleen, the liver, and the growth were sterile.

Microscopical and Pathological Notes, by Dr. W. E. REYNOLDS.—Selected pieces of tissue were immediately hardened in alcohol and in a saturated solution of mercury perchloride in normal saline; paraffin sections were stained with hæmatoxylin and eosine and with Unna's alkaline methylene blue and eosine. Ferro-cyanide of potassium and ammonium sulphide were also used. The spleen shows greater changes than were evident macroscopically; the capsule and reticulum are not much thickened; the Malpighian bodies are prominent and plugged with lymphoid cells, but the chief change is the large number of endothelioid cells in the pulp; these project into the lumen of the sinuses; many of them are free; they are large in size and show much phagocytic activity, containing numerous red and white blood corpuscles; others, again, contain granules of golden-brown pigment, which is so marked in places as to obscure their cellular structure. Generally speaking, the nucleus is pushed to one side of the cell and is faintly staining. The lymphoid cells of the Malpighian bodies are large in size, with rounded or reniform vesicular nuclei having a very sharply defined nuclear membrane and irregularly and centrifugally arranged chromatic substance; the granulation is mostly fine in character. Neutrophilic, basophilic, a few polymorph neutrophilic, and coarsely granular eosinophilic cells are present. Brown pigment is very evident in the fixed and free endothelial cells, especially in those near or round the larger blood-vessels; it is mostly intra-cellular, rarely seen in the nuclei, and occasionally free. The larger vessels show a slight degree of hyaline change.

In a hyperplastic inguinal lymphatic gland much the same changes are present. The sinuses are plugged with lymphoid cells similar to those in the spleen, and the germinal centres are obscured. There is also a marked enlargement and proliferation of endothelial cells, which seem actively phagocytic to red and white blood corpuscles. Pigmentary changes analogous to those found in the spleen are present but not so marked. The green lymphoid tissue from the sternum shows the same appearances; it consists of masses of leucocytes of unfamiliar type imbedded in a delicate stroma; they are similar to those found elsewhere; coarsely granular eosinophile cells are, however, more numerous. In places the cells have lost their sharp outline, are packed close to each other, and their nuclei which stain intensely show signs of disintegration. The vessels are well-formed, and newly formed capillaries seem to have arisen in places; their endothelial cells are also enlarged, proliferated, and phagocytic. Pigmentary changes are very evident; in places the individual cells are almost choked with pigment. These "pigment cells" are also numerous in the surrounding connective and adipose tissues. The kidneys show large groups of lymphoid cells of the same nature replacing the renal tissue. There is slight cloudy swelling of the tubules and some pigmentary change is present. The liver shows marked changes. Glisson's capsule is well seen and infiltrated with similar lymphoid cells which are partially obscured by slight hyaline change; the adjacent liver cells are apparently normal, their nuclei, however, are vesicular and the cytoplasm contains numerous granules of refractile brown pigment. The hepatic vessels are similarly affected but there is less infiltration; pigmentation, however, is marked. In places the liver cells are compressed by lymphoid cells, are vacuolated, and contain numerous granules of pigment.

The relation of chloroma to other diseases is very obscure. It is often classed with melanotic sarcoma under the pigmented sarcomata; some pathologists regard it as a form of leukæmia, others as a condition *per se* showing characters in common with leukæmia, the infective granulomata, and sarcomata. In this particular case the history, clinical course, and distribution of the gross lesions suggest an infective process. The morbid histology shows a general dissemination of what looks like lymphoma; on closer examination, however, we find that the blood-vessels are well formed and the presence of newly formed capillaries indicates changes analogous to those found in subacute and chronic infections. In spite of this the characters of the cells and their nuclei are indistinguishable from those seen in sarcomata. In the spleen we find excessive hæmolysis and, what is more remarkable, phagocytosis of white blood cells by endothelioid cells; we also find that the endothelioid cells in the other hæmopoietic organs have taken on these functions. The explanation of this may be either that the endothelioid cells themselves are primarily affected and are stimulated to an abnormal extent, or that the first effects fall on the leucocytes and red blood corpuscles, which are being rapidly destroyed as noxious bodies or as waste products. The increase of xanthin bodies, &c., in the urine gives clinical evidence of a nuclear destruction. Pathologically we may derive some information from the distribution and nature of the pigment as to the exact meaning of these processes; we must, however, bear in mind that the quantity of the pigment is greater than would be accounted for by hæmolysis alone, a considerable portion of it having been excreted in some form or other during life; it is thus possible that it is derived in part from cellular and nuclear destruction. With this in view and with the idea that we were probably dealing with an infective process I endeavoured to ascertain the chemical nature of the pigment. Analyses as accurate as were possible by the aid of the microscope and minute quantities extracted from the tissues showed that the pigment was of the nature of a fatty acid combined with iron and that, moreover, it had very strong reducing powers. This explains the rapid change in colour of the pigmented tissue on exposure to air.

The physical and chemical properties of the pigment are as follows. With potassium ferro-cyanide a Prussian blue colouration was obtained but with some irregularity and difficulty. With ammonium sulphide and gentle heat a black reaction was observed; this was also marked in the nuclei of the hepatic and splenic cells and very evident in the growth. Picric acid in the presence of dilute caustic potash was reduced, giving a red colour. Sodium nitoprusside and dilute caustic potash gave a ruby red, but, unlike creatinine, on the addition of acetic acid no Prussian blue was observed. The pigment was insoluble in water, dilute mineral acids, alcohol, ether, and chloroform, slightly soluble in ammonia, and it was considerably altered in boiling water or alcohol, in which it was partially soluble. The facts that it unites with some metals to form salts, that it is a powerful reducing agent, and that it gives the above chemical and physical reactions suggest some substance analogous to creatinine and creatine. By special fixation or solution of the pigment and by special staining methods (which I shall publish subsequently) it is possible to demonstrate a bacillus which markedly resembles the bacillus mallei both morphologically and in staining affinities. Its distribution is precisely that of the pigment and is chiefly abundant in the nuclei of the cells immediately adjacent to the growth, in the nuclei of the cells forming the growth, and in the cytoplasm of the hepatic cells and of the endothelioid cells in every organ; in these last the bacilli appear to be exceedingly numerous; in places the cells are plugged with them, in others two or three are contained within vacuoles; some are free in the blood and in the intercellular spaces of the growth. The bacillus is variable in size, usually of the size of a tubercle bacillus but somewhat thicker; some are larger, slightly curved, and sometimes show clubbing of one or both extremities, and their protoplasm is often broken up into a number of deeper stained bands; others are smaller, of about the same thickness, and exhibit marked bipolar staining; they all possess rounded ends so as to give the shorter forms a spindle-shaped character. I was unable to detect any definite back the breath sounds were puerile; in front they were faint, with prolonged expiration. The vocal resonance was increased over the base of the right lung. There were a few rhonchi all over the lungs and especially over the right base. His pupils were slightly dilated but equal, and reacted to light and to accommodation. On ophthalmoscopic examination numerous large and recent fan-shaped retinal hæmorrhages were seen, the discs were markedly œdematous and indistinct, and the vessels were not clear. There was a slight lateral nystagmus but no paralysis of the ocular muscles. The vision was markedly impaired, especially in the right eye. The colour sense was normal. His hearing was defective: one had to talk loudly to make him hear; he was quite unable to hear a watch tick with the right ear and could only just hear it with the left. The knee-jerks were absent; the plantar reflex was exaggerated but normal in type. There was incontinence of urine. His skin was moist and smooth. The temporal region was puffy but there was no discolouration. Over the external aspect of the right knee there was a large greenish yellow patch about three inches long, the periphery of which faded off into a yellow tint; another, two inches long, was present over the instep of the left foot; there was no sign of injury on the skin over these patches. On running the fingers over the subcutaneous surface of both tibiæ small hard nodules of about the size of a pea, continuous with the shaft of the bone, were felt. The specific gravity of the urine was 1010; it was alkaline in reaction, clear, and of a light amber colour; there was no albumin, peptone, albumose, or hetero-albumose present; there was a deposit of stellar phosphates.

A provisional diagnosis of acute leukæmia was made. The blood was examined on the day after admission. On puncturing the lobe of the ear it was found to bleed readily and continuously, the blood being very pale and its coagulability seemed decidedly diminished. The result of the examination was as follows: hæmoglobin, 45 per cent.; red blood cells, 2,450,000 per cubic millimetre; and white blood cells, 197,500 per cubic millimetre. Blood films stained by Jenner's and Ehrlich's stain gave a differential count of—large lymphocytes, 20 per cent.; small lymphocytes, 19 per cent.; polymorph neutrophiles, 14 per cent.; myelocytes (mostly large, one coarsely granular eosinophile), 25 per cent.; mast cells (coarsely granular basophile), 5 per cent.; coarsely granular eosinophiles, 6 per cent.; and unclassified, 11 per cent. Transitional forms were so numerous that an accurate count was difficult; there were no large mast cells such as are found in spleno-medullary leucocythæmia. The white cells were generally of a good shape, with the exception of a few myelocytes, which showed irregular or double nuclei and disintegration and vacuolation of their cytoplasm. The red cells were of good shape, normoblasts were scanty, while blood platelets were numerous. On Feb. 19th he complained of failing eyesight; chemosis was more marked; the pupil reflexes were, however, normal. The yellow spots which had the appearance of pustules were more numerous; on cultivating the contents of these a pure growth of staphylococcus albus was obtained. On the 21st the patient was weaker; he complained of intense thirst and vision was less distinct. There was complete ophthalmoplegia of the right eye, whilst on movement the left showed a lateral nystagmus. The left pupil reacted to light. He could only distinguish objects a few inches away with his left eye. A small swelling of about the size of a marble had appeared on the right temporal region; this was circumscribed, soft, and deep fluctuation was elicited; there was no pain or redness. The nodes which were present on admission were appreciably larger. A culture taken from the blood proved to be sterile on aerobic cultivation. On the 23rd the eyes were more prominent, the swelling on the right temporal region was more pronounced and semi-fluctuant, and it had acquired a distinct pale greenish tint. The gums were bleeding slightly. The patches on the legs and feet had remained of the same tint, but had become more extensive. He was decidedly more anæmic, as was confirmed by a blood examination which showed considerable alteration: hæmoglobin, 25 per cent.; red blood corpuscles, 900,000 per cubic millimetre; and white blood corpuscles, 360,000 per cubic millimetre. Differential count: large lymphocytes, 19 per cent.; small lymphocytes, 17·5 per cent.; myelocytes, 32 per cent.; polymorph neutrophiles, 8 per cent.; mast cells, 6·5 per cent.; coarse eosinophiles, 2 per cent.; and unclassified, 15 per cent. There was a marked increase of blood platelets, the red cells showed considerable granulation and poikilocytosis, and normoblasts were still scarce but distinctly increased. A fresh film in a warm stage showed very little amœboid movements of the cells. On the 25th the patient was much weaker; he was delirious and cried out frequently, complaining of intense pain in the eyes. There were complete ophthalmoplegia of both eyes and total deafness. Small subcutaneous nodules of about the size of a pea were found on the outside of the left leg; these were firm and painless and not discoloured. Adventitious sounds were more numerous at the bases of both lungs. On the 26th he was obviously dying; he was still delirious and crying out with pain; he now had incontinence of fæces as well as of urine; his pulse was irregular and small in volume. On the 27th he became comatose and towards the evening the respirations became more laboured and 44 to the minute. His pulse was fuller in volume and numbered 120 beats per minute. There was a small patch of dulness in the left interscapular region, over which the breath sounds were tubular in type and the vocal resonance was increased. His temperature remained much at the same level. He gradually became worse and died at 4.30 A.M. the following morning, 14 days after admission. His condition was one of a rapidly progressing anæmia, with an irregular continued fever varying between 101° to 99° F. His spleen became appreciably larger; nine days after admission it was three inches below the costal margin, and two days later it had increased half an inch further down; it was always slightly tender on palpation. No progressive glandular enlargement was detected. A conspicuous feature was the absence of pain during the whole of his illness, with the exception of the last day or two.

At the post-mortem examination seven hours after death rigor mortis was well marked. There was no hypostatic lividity, but some post-mortem discolouration of the abdomen was present. Nutrition was impaired. Both eyes were much proptosed and chemotic. There were three firm nodules just below the skin of the left leg on the course of the veins. On removing the sternum large flat masses of greenish tissue were present under the periosteum; on section they consisted of greenish substance, the colour of which faded rapidly on exposure. The heart was large and pale. The thymus weighed one and a half ounces; on section it was hard and firm and of a greenish mottled appearance. The pericardium contained half an ounce of clear fluid. The heart was distended; there were several greenish patches below the epicardium measuring up to 1·5 centimetres in diameter; numerous subpericardial hæmorrhages were seen. The right chambers and valves were healthy; a large, soft, ante-mortem clot occupied most of the auricle. Some greenish nodules covered by healthy endothelium were distributed along the auriculo-ventricular ring. The muscle was pallid but healthy and measured 0·5 centimetre at the thickest part. The left chambers and valves were healthy; the muscle was 1·5 centimetres thick. The right lung weighed 9 ounces and was adherent firmly to the posterior and upper parietes; the middle, upper, and lower lobes were fused together. The surface was of a mottled greenish colour; on section it was of a mottled green and pinkish colour; round the bronchi there was a deposit of greenish tissue. The left lung weighed 16 ounces; it had a greyish mottled surface, the upper lobe being congested and œdematous. The lower lobe showed a small patch of broncho-pneumonia. The spleen weighed 70 ounces, was much enlarged, and pale in colour; a few greenish masses were present near the entrance of the large vessels; on section nothing was noticeable; the Malpighian bodies could not be seen; the general substance was soft. The kidneys were large; the capsule stripped easily and revealed a striking greenish mottled surface with numerous small hæmorrhages; on section the cortex was increased in size and the colour was like that of the surface. The left weighed 10 ounces and the right 8 ounces. The mucous membrane of the urinary bladder had a green appearance. The liver weighed 2 pounds 3 ounces. The gall-bladder was distended with dark greenish bile; it was markedly thickened and showed considerable green pigmentary change. The liver surface was pale and there was a small patch of greenish tissue below its serous coat. On section it presented a most striking appearance; triangular-shaped green deposits of considerable size, varying from 1·5 to 0·75 centimetres, surrounded the larger vessels. The pancreas showed marked catch it and paralyse it and so may mediastinal growths or enlarged glands, but more important than these, because very fatal and often latent, is aneurysm of the aortic arch.

Referring to Dr. F. de Havilland Hall's well-known work on "The Medical Examination for Life Assurance" he says: "The records of life assurance offices show that thoracic aneurysms are *frequently overlooked*. In many instances this omission is almost unavoidable, as even when a patient is anxious to give all the information he can the physical signs are often too ill-defined to enable a diagnosis to be arrived at." This I heartily endorse, at the same time suggesting that if these cases had had their larynges examined perhaps danger signals might have been detected in some of them. In these cases of aortic aneurysm the left nerve, as might be expected, is the one generally affected, but sometimes both are involved; and the cause of this has led to much discussion, some explaining it on the ground of the aneurysmal dilatation having extended into the right subclavian and involving the right recurrent as well as the left; but it has also been shown that pressure on one vagus may, by acting reflexly through the afferent fibres, produce paralysis of motor fibres on both sides.

The onset of paralysis is insidious and peculiar, and with reference to it I must quote the work of Sir Felix Semon, whose investigations in this, as in other matters on laryngology, are of marked and permanent value. Semon's law says: "In organic progressive diseases of the roots and trunks of the spinal accessory, vagus, and recurrent nerves the dilator fibres are affected earlier than the constrictor fibres, or may be even attacked exclusively," and the law holds good in this case. Now the dilator muscle of the larynx or abductor of the cords is the crico-arytenoideus posticus, and it is better to speak of posticus paralysis rather than abductor, because the terms "abductor" and "adductor" are so much alike that confusion is apt to arise. Therefore, if one sees the larynx early it is noticed that the posticus or dilator only is paralysed and the vocal cord lies motionless in the middle line; in this stage, however, when one cord only is affected, there may be very little, if any, alteration in the breathing or phonation, the outward movement of the cord on the unaffected side during inspiration giving sufficient room. Should, however, both postici be paralysed, both cords lying near the middle line, there is no room to breathe and the danger of suffocation is great. Though neither voice nor breathing may give much warning in this early stage of paralysis of one cord, yet in some cases attacks of difficult breathing and alteration of voice due to spasm of the muscles of the cords occur, the cause being irritation of the nerves. If, however, the condition has passed on to complete paralysis of one cord the voice is weak and more or less hoarse and sometimes with a tendency to falsetto when the patient attempts to speak loudly, but there is no dyspnœa; on examining laryngoscopically it will be found that the paralysed cord lies motionless in a position very near to that which it assumes in the dead body and which is known as the cadaveric position. On making the patient phonate it may be seen that the healthy cord comes right across over the middle line and approximates itself to the paralysed one, so helping its weak partner to produce a voice.

Although complete left sided paralysis is the commonest form observed, yet one may get various combinations, such as complete paralysis on one side and partial on the other, the difficulties being phonatory when there is complete paralysis and respiratory when the dilators *only* are affected. It has been pointed out that the tactile vocal fremitus is different on the two sides of the larynx when one cord only is paralysed, but I do not think much weight can be attached to this. Movement, too, of course, may be communicated to the trachea and larynx by the tugging of the aneurysm, especially when the patient's head is held backwards. Also, seeing that the aorta lies close to the anterior surface of the trachea just above its bifurcation and then curves backwards and to the left over the left bronchus, one may find stenosis and stridulous breathing from pressure here, and if the glottis can be well dilated one may sometimes see the pulsation with the laryngoscope in the lower part of the trachea, especially on its left anterior wall.

Leaving now the aorta and aneurysm, let us turn our attention to *another* point at which the recurrent laryngeal nerves are often pressed upon with resulting paralysis of vocal cords. These nerves, you will remember, passing upwards and backwards behind the subclavian on the right side and the aorta on the left, reach the groove between the trachea and œsophagus, and continuing their course towards the larynx reach the lower border of the cricoid cartilage where they pass beneath the inferior constrictor muscles of the pharynx, and should they be caught in this region a serious significance must often be attached thereto. Let me illustrate what I mean by a case. In 1897 a man brought his wife, aged 40 years, to me, stating that he was thinking of insuring her life, but wished me just to examine her to see if her various organs were in a sound condition. In answer to my inquiries as to her state of health she stated that she enjoyed very good health indeed, but had lately had a slight hoarseness and a little pain in the right ear which she considered to be due to a cold. She had no difficulty in swallowing, but a curious point was that she had recently nursed a sister who had, she stated, died from cancer of the tongue. On making a laryngoscopical examination I found that she had complete paralysis of the right vocal cord, and at the base of the arytenoid on this side there seemed to be some fulness on its œsophageal aspect, but nothing could be felt externally, nor was there pain or tenderness here, but I could not help feeling highly suspicious as to the nature of this swelling, thinking that one had in all probability to deal with a malignant growth of the œsophagus in an early stage. This opinion was confirmed by Dr. H. Lambert Lack, who saw her at my request shortly afterwards. In March, 1899 (about two years later), I saw her again when almost moribund and a few days afterwards was allowed to make a post-mortem examination, when I found a mass of growth involving the recurrent laryngeal nerve on the right side, and this was shown by microscopical examination to be an epithelioma.

Now it would not have been worth while referring to this case but for the fact that this condition is by no means a rare one, and it is a common thing—at any rate, at a throat hospital—to see a patient with commencing malignant disease of the upper part of the œsophagus with very little indeed to show for it except paralysis of a vocal cord. It also occurs in comparatively young persons and I have seen it myself in a woman aged 28 years. In some goitres also paralysis of the vocal cords may be produced by pressure on the recurrent nerves, but with them external swelling is generally obvious and the examiner is not likely to be taken off his guard.

As regards nerve degenerations, we may find paralysis of the vocal cords in bulbar paralysis, disseminated sclerosis, and syringomyelia, amongst other diseases, but being rarely if ever the earliest symptom of these diseases it has but little importance here from a life assurance point of view, but in tabes dorsalis laryngeal paralysis may be the first sign, and the typical paralysis of tabes is the before-mentioned paralysis of the crico-arytenoideus posticus or abductor of the cord. This may occur on one side or both, but various forms of paralysis may be met with, and the condition may be so marked as to produce a very noticeable alteration in the voice or respiration, or so slight in effect as to be hardly observable, and the paralysis also may develop very gradually. Besides, irregular or ataxic movements of the cords may occur on the patient attempting to take a deep inspiration or use the voice, which latter may be interrupted and the speech jerky; or there may be the history of laryngeal crises, in which the patient generally feels an irritation or tickling in the throat and gets a violent convulsive cough with noisy respiration and dyspnœa. The attack is often followed by paralysis of the cords, so that if owing to any such history or to hoarseness or dyspnœa we examine the larynx and find paralysis locomotor ataxia is one of the diseases to be thought of and confirmatory evidence should be sought for in the eyes, knee-jerks, &c. In general paralysis of the insane—a very fatal disease—the patient very often exhibits more or less marked posticus paralysis, and a case in which laryngeal spasm was the precursor of the disease has been recorded.

Let us now leave paralysis of the recurrent laryngeal nerve and pass on to the conditions in which phonation and respiration are interfered with by mechanical causes in the larynx, first, however, remarking that ankylosis of the crico-arytenoid joints may produce appearances and loss of movement very similar to those due to paralysis, but sometimes swelling can be noted round the joint in ankylosis and there is more rigidity of the parts. As regards the intralaryngeal mechanical causes of loss of voice and interference with breathing, they are many, but from a life assurance point of view three only may be regarded as sufficiently common and important to dwell on—viz., (1) malignant spore formation or to stain them by Gram's method. It is stained faintly and with difficulty by basic stains and is easily decolourised with weak acids and less so with alcohol. Cultivation was unsuccessful both from the blood taken during life and from the blood and organs post mortem. Inoculation with blood taken during life was unsuccessful.

The association of the bacilli with the pigment is supported by their distribution (they are specially numerous in endothelioid and "pigment cells"), by the fact that potassium ferro-cyanide and ammonium sulphide show blue and black granules respectively, which in places are distinctly bacillary and in others bipolar in shape; we have further evidence in the fact that unless the pigment is either fixed or extracted they cannot be demonstrated. Their presence in large numbers in a hyperplastic gland excised very shortly after death and immediately hardened excludes the possibility of a post-mortem contamination. Against the hypothesis that they are pathogenic it can be urged that the defensive cells and their generating centres are diseased, have lost their function, and hence the infection may be accidental rather than causative; in answer we have the absence of any other organism in the tissues and the evidences that free and attached endothelioid cells are actively phagocytic to this bacillus. I admit that there is no normal round cell infiltration such as we find in acute infections, but the absence of leucocytes from the blood capable of amœboid movements should be remembered.

Taking a comparative view of acquired immunity we find that resistance to infective agents is mainly accomplished by phagocytosis and intracellular digestion, and also by other changes, such as the formation of agglutinins and antibodies from leucocytes and every cell in the body in general; an important part is also played by the "fixed phagocytes"—connective tissue and endothelial cells. Pathogenic bacteria are also known to protect themselves from antibacterial agents by the formation of impervious capsules or hypertrophy of their sheaths.[1] I may also cite the well-known fact that the tubercle bacillus in a giant cell secretes a fatty envelope which is protective against the ferments of the giant cell, and that the giant cell thus deprived of one means of attack deposits calcium salts, &c., around or into this envelope, in order to isolate the bacillus and its products. It is possible that pigmentation such as we find in this case is an analogous process. The immunising influence of fats and fatty substances is also of common occurrence.[2] These facts fit in with the chemical and physical characters of the pigment found in this case. On the little evidence we have at present on one case only we cannot decide whether this bacillus is pathogenic or merely living as an accidental saprophyte, but the facts are significant and I favour the former view. I regard this disease as one in which the first effects fall on the cellular elements of the blood or on their germinal centres, thus depriving the body of its chief defence, which now has to be performed by minor and less perfect means, such as phagocytosis by endothelioid cells and the formation and deposition of impervious substances. In the meantime further investigations into diseases showing leukæmic changes are necessary. It remains to account for the masses of lymphoid cells. I do not consider them to be wholly comparable to the infective granulomata but rather to be collections of already damaged leucocytes deposited in various places, such as lymph spaces around visceral vessels and subperiosteal spaces.

My thanks are due to Dr. Pope for his permission to carry out and publish my investigations and to Mr. C. J. Bond for his valuable suggestions.

DISEASES OF THE UPPER RESPIRATORY PASSAGES IN RELATION TO LIFE ASSURANCE.[1]

BY W. H. KELSON, M.D. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON AND PATHOLOGIST TO THE LONDON THROAT HOSPITAL, GREAT PORTLAND-STREET, W.

LOOKING through the list of questions to be answered in the medical reports of several life assurance companies taken at random, one is struck by the absence or extreme paucity of reference to the upper respiratory tract, and one is tempted to ask the question,—Are there no serious troubles arising in these parts affecting longevity? or are there no signs nor symptoms to be looked for here which might guide us to the discovery of serious disease in other parts? True, there are difficulties obviously in the way of the examination of these regions, more especially the nose, post-nasal space, and larynx, and I am not going to suggest for a moment that any routine examination of these parts should be made in all cases, but, on the other hand, if you will bear with me for a little while, I will endeavour to show that perhaps more complaints than are generally supposed may have their origin here, and that sometimes the very earliest signs of very grave organic disease appear here, and, if recognised, put us at once on our guard in the same way as that in which one is put on the *qui vive* by unexpectedly coming across albumin in the urine. Also, as regards the nose, the physiology of this organ has of recent years had to be rewritten, and its functions have been found to be more numerous and important than was formerly supposed and consequently their abrogation by disease more serious.

Let us begin with the larynx, and ask what symptoms are there which should make a laryngoscopical examination of a candidate for life assurance desirable and what physical signs may be detected on so doing, for though the value of any laryngoscopical examination depends largely on the skill and experience of the examiner, yet it may be well to recapitulate briefly some of the principal points to be observed in relation to their value as indicating serious mischief. Speaking generally, we may say that the question of this examination is most likely to arise in young adults of poor physique and any adult about or just beyond middle life. Now the functions of the larynx are respiratory and phonatory, though the existence of the larynx is by no means a necessity for audible intelligible speech or respiration; therefore, the symptoms will be some change in, or interference with, phonation or respiration; and it having been decided to make a laryngoscopical examination, what abnormal appearances may be present to indicate to us the presence of disease which will have a bearing on the prospects of the candidate as regards longevity?

First of all, there may be loss of movement of the vocal cords; that is to say, the outward motion of the cords on getting the patient to take a deep breath, or the inward movement on getting him to phonate, is defective. Now this loss will be due to one of two main causes: either paralysis or mechanical interference. Let us first take paralysis. This may sometimes be due to a toxin, such as in diphtheria or influenza, when it has no special significance or may occur as part of a general poisoning such as from lead (two cases of cord paralysis from this cause I have seen) and from arsenic, as reported by Seligmüller and Heymann, but more commonly the paralysis is due to either (*a*) pressure on the nerve or (*b*) degeneration of it or its centres. Let us take pressure first. Now the laryngeal muscles, as is common knowledge, are supplied by the recurrent laryngeal nerve, a branch of the vagus, with the sole exception of the crico-thyroid, supplied by the superior laryngeal. As to the vexed question whether the ultimate origin of the fibres be the vagus or the spinal accessory, we need not, I think, trouble ourselves this evening, and I may say at once that paralysis from pressure on the vagus above the point of origin of the recurrent laryngeal is very rare but the recurrent itself in the course of development having been caught, as it were, by the aortic arch on the left side and subclavian artery (the representative of the fourth right fœtal arch) on the right, and looping round these structures, is peculiarly exposed to pressure here—e.g., an apical pleurisy or a pericarditis may says: "Leucoma is undoubtedly a very strong predisposing cause of cancer"; also, "It may almost be thought that the possibility that carcinoma may be developed in connexion with leucoma has been exaggerated, so much has been said and written of it lately, but we believe that the frequency of the event, so far from having been exaggerated, has been underrated, and that careful records will show a much larger proportion of carcinomas, which have been preceded by leucoma." And it may be said at once that if in these cases of leucoma any ulceration with induration be present we may be pretty certain that the carcinomatous stage has actually been reached. In fact, nowhere is a pre-cancerous stage shown more clearly than in the tongue, and the change going on from leucoma to cancer may be sometimes seen in different parts of the organ at the same time. Leucoma is all the more important because the subjective symptoms are apt to be so very trivial and the pain slight, so that the patient may be unaware of its existence till it is pointed out by the examiner. Ulcers of the tongue also are common and must always be looked on with suspicion, for they are not unfrequently the only indication present of active syphilitic disease, and when this is not present gouty dyspepsia or local irritation will be the most probable cause, but in all cases it is desirable to make quite certain what course the ulcer is going to run before giving a definite opinion. Tuberculous ulceration here or in the pharynx is almost always accompanied by well-marked pulmonary tuberculosis.

---

[1] A paper read before the Life Assurance Medical Officers' Association on March 6th, 1907.

When examining the tongue a view can easily be obtained of the palate and one sometimes sees evidence of syphilis here in those apparently unaware of its presence. Also, by getting the candidate to protrude his tongue and say, "Ah!" we can eliminate the presence of any loss of movement of tongue or palate, such as, combined with laryngeal paralysis, we find in diseases affecting the bulbar nuclei or the surface of the medulla.

In concluding these few and I fear rather disconnected remarks I would submit for your consideration the question as to whether such queries as, "Do you ever suffer from hoarseness or difficult breathing?" "Can you breathe freely through your nose?" "Have you any mattery discharge from it?" and, "Is your tongue sore?"—might not each or any of them be put to candidates. Also, I should like to get the opinions of those present as to in what circumstances the medical examiner should advise his office to postpone the life until a further examination and conclusive opinion can be obtained. Not so very long ago a running ear was not regarded as having any very great import, but facts have shown this to be a matter requiring serious attention from the view of life assurance, and as our knowledge of rhinology and laryngology increases a pus-discharging nose may be found to have perchance an equal or even greater bearing on a candidate's prospects of longevity than a pus-discharging ear.

Cavendish-place, W.

SOME CLINICAL OBSERVATIONS ON MUCO-MEMBRANOUS COLITIS.

BY J. LIDDELL, M.D. EDIN.,
PHYSICIAN TO THE HARROGATE ROYAL BATH HOSPITAL.

DURING the last few years the attention of the profession has been increasingly drawn to the affection called muco-membranous colitis. It is an extremely common malady but one that is liable to be overlooked. Its importance is considerable not only on account of the local symptoms but more because of the secondary effects due to an auto-intoxication. It is the toxic poisoning arising from the condition which gives the real importance to the affection, since this toxin seriously impairs the health and gravely interferes with the well-being and usefulness of a large number of people. The principal objects of this communication are, first, to indicate the clinical manifestations useful in helping us to recognise the malady when there is no history of the evacuation of mucus from the bowel; and secondly, to describe the method of colon irrigation which has proved so beneficial in the treatment of such cases.

Muco-membranous entero-colitis is a chronic malady affecting the colon but occasionally implicating the lower part of the small intestine. The symptoms may run a continuous course or there may be intermissions followed by exacerbations. In respect to the local manifestations of the disease I shall merely indicate these, as it is unnecessary for me to dwell upon them since they have been well described by various English and continental observers. I shall, however, describe more fully the secondary features, not only on account of their importance to the patient but because they are helpful in enabling us to recognise the disease in obscure cases.

Many of the patients who are classified as neurotics or neurasthenics are sufferers from colitis and there is a causal connexion between their neuroses and the colitis. Indeed, so much is this a fact that most of the obscure cases of colitis can be recognised by the nerve symptoms accompanying the condition, especially when they occur in conjunction with other manifestations which I shall mention. Without further preliminary I shall enumerate the symptoms which usually occur in typical cases of colitis.

SYMPTOMS.

The patients complain of malaise; they have occasionally depression of spirits and irritability of temper; often there is sleeplessness or disturbed sleep, loss of memory, impairment of mental and bodily faculties; they are easily moved to tears, and they suffer from cold hands and feet. Though these symptoms may not be peculiar to muco-colitis, yet a surprisingly large number who complain of them are subjects of that affection. Should this group of symptoms or most of them occur in a patient then we ought to inquire into the state of the intestine. The cardinal symptoms referable to the abdomen are constipation, pain, and the evacuation of mucus. The constipation generally is of an obstinate and intractable character and occurs in the majority of cases. Sometimes it alternates with diarrhœa, but this is often spurious. A few cases, however, have habitual diarrhœa or looseness of the bowels. There is usually pain or discomfort in the abdomen and this is often referred to the cæcum, where it may be mistaken for appendicitis. The next most frequent site of pain is the sigmoid flexure, especially in those cases where spasm occurs in the descending colon. Here, as in the cæcum, we must be careful to distinguish it from ovarian pain. Pain may also occur in the hepatic and splenic flexures, also in the neighbourhood of the umbilicus. In respect to the evacuation of mucus many colitis patients are not aware that they are passing it from the bowels, either because the quantity is small or more often because it is evacuated in a state unrecognisable by the ordinary observer. If there is no history of the evacuation of mucus and we proceed to examine the patients there are certain features which aid us in detecting these obscure cases of colitis.

The first thing to be noticed in cases of long duration is that the skin is toneless and has a dull yellowish or dirty-brown tint. There are sometimes numerous pigmented patches in the skin, which may be elevated or not. The face wrinkles early and in many cases there is a curve round the angles of the mouth. Many patients are thin through atrophy of the muscles and loss of fat. The circulation is weak and the arterial tension is low. The tongue is often very large and beefy-looking, indented at the edges by the teeth, and in cases of long duration is deeply fissured at the edges and on the dorsum. This is characteristic of the condition. When the tongue is coated there is usually gastric catarrh or dilatation of the stomach. The lips are often cracked and in severe cases the buccal mucous membrane is affected with tiny ulcers. On examining the abdominal walls we usually find one of two conditions. Either the walls are thin and retracted, due to loss of fat and atrophy of the muscles; or they are loose and pendulous, producing the so-called "batrachian belly." By palpation and percussion information is obtained as to the state of the colon. The ascending and transverse portions are distended, whilst the descending is often contracted, especially in the neighbourhood of the sigmoid flexure. This contraction feels like a piece of indiarubber tubing. With deep pressure gurgling or crepitation can be felt chiefly in the cæcum. Auscultation often elicits splashing in the transverse colon when the abdomen is given a slight shake. The kidneys are frequently moveable, the right especially so. The fæces are sometimes pale in colour or pale portions may be seen with ordinary motions. Frequently the motions are attenuated, being of about the size of the little finger; this happens when there is a spasm in the descending colon. Again, they may vary considerably in appearance and consistence, sometimes occurring in small rounded masses or shattered and irregular. Scybala are disease; (2) tuberculous; and (3) syphilitic lesions. Taking first malignant disease, this affection loses some of its significance owing to the large proportion of cases which occur at over 50 years of age, but a considerable number are met with below 50, though of late years operative treatment—for such as are dealt with in the early stages—has rendered the prognosis much more hopeful. Fortunately hoarseness is commonly a very early symptom, a usual situation for the growth being one of the true vocal cords; therefore, suspicion being aroused, a laryngoscopical examination should be made, and in proportion as any growth present shows a tendency to infiltrate the parts and interfere with movement by its infiltration so the probability of its being of a serious nature is increased. Removal of a portion of the growth and its examination by a skilled pathologist is in doubtful cases the only way in which the innocence of a growth can be proved, and unfortunately here the objection is constantly raised that the piece removed may not have been deep enough to give a fair sample of the growth itself, and to get a sufficiently large specimen for a decisive opinion is often well-nigh impossible without doing serious damage to the parts. In the early stages of intra-laryngeal malignant disease glandular enlargement is improbable.

Laryngeal tuberculosis may be either primary or secondary, though the primary form is undoubtedly rare and opportunities of proving by post-mortem examination that it may exist are rarer still; yet, on the other hand, there are many cases in which the lung signs are very slight and others in which lung indications seem absent, but subsequent history shows that in all probability the lung affection preceded the laryngeal disease. These cases have considerable importance from a life assurance point of view, as they occur in young adults and more often in men than women, and also because the laryngeal symptoms may draw attention to the presence of pulmonary tuberculosis which possibly might be otherwise overlooked. In these cases there is commonly only hoarseness at first with perhaps tickling or pricking in the throat and irritable cough, and sometimes the history of a previous attack of laryngeal catarrh. On examination the first thing as a rule that strikes one is the peculiar pallor of the larynx, and the commonest position for the tuberculous deposit is the inter-arytenoid space where it may either form one or more slight swellings or a distinct tumour jutting out, so as to prevent the vocal cords coming into opposition and so interfering with voice production. The vocal cords and epiglottis are also commonly affected, but one of the points in differential diagnosis between an ordinary catarrh and these more serious troubles is the less general involvement of the parts in these latter. Thus one cord being swollen and not the other is a suspicious sign; of course, finding tubercle bacilli would clinch the diagnosis, but at this stage the sputa may be very scanty and contain none.

With regard to syphilis, in the secondary stage of this disease hoarseness is common, and I have known this lead to the discovery of the presence of this affection. In the tertiary stage it frequently affects the larynx, and then, as in other parts, simulates malignant and tuberculous disease and may attack any part. Speaking generally, it shows less tendency to warty growth and insidious infiltration than malignant disease and more dusky redness than tubercle. Age, sex, and past history help sometimes, but are apt to prove deceptive. The swelling is often marked and has the special danger here of interfering with respiration at first and also later sometimes by troublesome fibroid contraction.

Let us now pass on to the nose and naso-pharynx. Referring to books on physiology of 20 years ago we find, although referred to in a vague sort of way as affording the natural passage for respiration, yet the nose was accredited with very little beyond that of being the organ for the sense of smell, but owing to the work of Bloch, MacDonald, and others it has been shown to have certain duties in addition, and, if anything, more important—that is, more closely connected with health than olfactory ones. The inhalation of air at an improper temperature, or of too great a degree of dryness, or full of impurities is detrimental to the lower air passages and is apt to be a source of disease, but by scientific experiment it has been shown that however cold or hot within a very considerable range (– 7° C. to 45° C., MacDonald) external air may be, after passing through the normal nose it will be reduced to approximately the temperature of the blood, and at the same time, if dry, it will be saturated with moisture. Impurities are also removed; in fact, some have attributed a bactericidal action to the nasal mucus. These facts being allowed, there can be no doubt that all blockages here, whether due to adenoids, polypi, cartilaginous, bony, or polypoid growths, or consisting of hypertrophied mucous membrane, &c., by interfering with the proper air-way through the nose, have a very deleterious effect on the respiratory organs below and indirectly damage the general health and, at any rate, predispose to bronchitis, pneumonia, and pulmonary phthisis, which figure so largely in the tables of mortality of insurance offices. Besides, associated with the obstructed nose we get mal-development of the jaws and with them the teeth, so that mastication is interfered with and digestive troubles arise; also associated with congestion and obstructed drainage of mucus from the nose and its accessory cavities are middle-ear catarrh and suppuration. So marked is this in the case of adenoids that the suppuration often ceases like magic when the growths are removed. Besides these, there are other conditions here which bear upon the question of longevity. Let us just take the signs of epistaxis. This occurs commonly enough in children, where it has no special interest for us, but in young adults one must remember the possibility of fibrous polypus and sarcoma, hæmophilia, and the oncoming of typhoid fever and the various forms of anæmia, and it may be an early symptom of splenic leucæmia—and one must not forget that the lungs are often blamed for hæmorrhage, the seat of which is really the nose, the mouth, the pharynx, or the larynx; especially is this the case in instances in which spitting of blood is reported after the night's sleep, that is after the recumbent position has been assumed for some hours. As age advances, however, the significance of epistaxis greatly increases and hospital records show that in cases over middle life in which the hæmorrhage has been so severe as to necessitate them becoming in-patients a very large proportion are suffering from visceral disease of a serious character, the most common being cirrhosis of the liver and contracted granular kidney with urine of low specific gravity and a trace of albumin.

Another trouble which has some importance besides a discharge of blood from the nose is a purulent discharge, and this gathers in weight if associated with headache or pain round the orbit, for suppurative disease of the accessory sinuses and ethmoidal cells is common, and from time to time one sees recorded fatal cases arising from these troubles, and instances of this fatal result have been collected by Grünwald and others; but there is reason to believe that owing to the difficulties present in the way of accurate diagnosis this cause of intracranial disease has been overlooked in a good many cases. Considering the very large percentage of deaths claimed by tuberculous disease, it may be well to note how tubercle affects the nose, and it is very significant how close the nasal cavities are to the meninges, and also their being on the direct highway to the lungs, since tuberculous meningitis and pulmonary tuberculosis are so common. A large number of cases of tubercle in the nose have now been collected, and it may be either primary or secondary, the former being the rarer form and taking generally a polypoid shape, whereas infiltration with ulceration is that usual in the secondary variety. Tubercle bacilli have been found over and over again in adenoids and tonsils, though the latter showed no sign thereof externally except enlargement and frequent association with tuberculous lymphatic glands; probably moderate enlargement, apart from this, need not affect a policy.

Seeing that the back of the mouth, the tongue, and the soft palate, together with the pharynx, are used by both the respiratory and alimentary functions as common ground it would seem that consideration of affections of the upper respiratory tract should include these parts though they are often omitted. As regards the tongue, it should always be examined and no question of inaccessibility can be made here, one great reason being the valuable indications it may give of the candidate's past life, history and habits, such as a tendency to chronic alcoholism, as shown by the furred tongue inclined to tremor with a more or less characteristic odour of the breath. In chronic superficial glossitis, also, we have a complaint both common and important with its various forms or stages, as leucoma, psoriasis of the tongue, and the red glazed smooth form. Its exact etiology may be somewhat obscure, but syphilis, excess in smoking, and alcohol (especially spirits), stand out pre-eminently as contributors to its development, and gout and rheumatism are also believed by Mr. H. T. Butlin to be [illegible] and cancer this high authority: factors. As re the apparatus for washing out the colon. This consists of a double cylinder, with a float in the lower cylinder, which regulates the escape of water from the upper, so that the same pressure is maintained throughout. The cylinder glides on two graduated uprights which mark the height and pressure and is moved to the height prescribed. There are a thermometer attached to the cylinder and a gauge to register the quantity of water, both sufficiently large for the patients to observe for themselves whilst lying on the couch. One of the sulphur waters is used for irrigation. The quantity prescribed may be from 10 to 40 or more ounces for each douche and is usually repeated. The temperature varies from 96° up to 104° F. or more, depending on the condition of the bowel. A long tube is passed per rectum into the sigmoid flexure and the sulphur water gradually passes through it into the colon. This is retained several minutes by the patient and is then ejected into a flat-bottomed receptacle. The douche is always given by a skilled attendant, who examines the ejecta and reports to the medical attendant. Immediately after the internal douching the patient goes into an adjoining room and steps into a warm sulphur bath. Whilst reclining in this a hot douche is directed through the water to the abdominal wall. It is delivered through a large nozzle with numerous fine perforations and moved slowly over the site of the colon. There are several therapeutic actions produced by this internal and external treatment besides the mechanical one of cleaning out the intestine. The internal douche acts as a warm bath upon the intestine, the heat of this soothing it and the neighbouring organs. Then the sulphur water brought in contact with the mucous membrane produces its well-known action of diminishing catarrh and restoring the mucosa to a healthy condition. Again, Sir William Ramsay has found that the stronger of the sulphur waters used is radio-active, and doubtless this property is beneficial, producing a sedative effect upon the bowel and the body generally. Another important action of the internal douche is free diuresis. This arises partly from the kidney being stimulated by the hot internal douche, though chiefly from the absorption from the bowel of some of the sulphur water, part of which is retained and subsequently secreted. This flushes out the liver, kidneys, and tissues, and carries away some of the toxins already absorbed.

When we come to examine the effects of the external treatment we find the warm sulphur bath soothes the nervous system and induces a sense of comfort in the patient. It determines an increased flow of blood to the skin, stimulating its glands and improving its nutrition. This in turn has a healthy influence upon the colon as there is undoubtedly a close relationship between the skin and the intestine, a state frequently demonstrated in colitis. The external douche applied to the abdominal walls has an extremely soothing effect upon the colon, relieving pain and spasm when it exists. Further, the impact of the tiny jets of the douche stimulates the intestine and promotes muscular contractility in the distended portions. It is an interesting fact that the relief of spasm in one part of the intestine and increase of contractility in another will take place at the same time, probably from the irritation of the intestine being allayed. After four or five weeks of such treatment a marked amelioration is produced in the patient's condition. The catarrh is lessened, pain and spasm are alleviated, and constipation is relieved.

Coming to the general symptoms the first thing noticed is the improvement in the appearance of the skin. In a few days it becomes clearer and brighter. Next, if there is glycosuria it usually quickly disappears, as does also the stool pallor. Soon the patient feels better and becomes brighter and happier. The neuroses, which are generally the most troublesome features in severe cases, improve slowly, though in the milder forms of the affection they are soon ameliorated. One remarkable circumstance is the effect of treatment on a loose kidney. After some months of effective treatment it becomes much less moveable, and in some cases when recovery from colitis has taken place the kidney becomes practically fixed. In severe cases of colitis one course of colon irrigation is not sufficient. It must be repeated once or oftener after an interval, depending on the state of the patient at the end of the course and subsequently to it.

During the last three or four years this treatment has been employed at Harrogate in several hundred cases of colitis. The excellent results which have been achieved have exceeded [illegible] s. The results prove that the method is both rational and successful and that it is destined to become an essential part in the treatment of many cases. The same kind of treatment has been carried out at Plombières and Châtel-Guyon for several years.

Careful dieting during and after the course of douching is imperative. Foods which are easily digested and leaving only a small and unirritating residuum are best. In my experience the diet advocated by von Noorden proves unsuitable. Further, the patient should be instructed to eat only a small amount of animal food, since it is a fruitful source of putrefactive material. They require to be warmly clothed and be careful to avoid chills, which are apt to increase the catarrh of the colon. Warm bright sunshine is a valuable aid to treatment and sometimes is indispensable. Moderate exercise should be regularly taken in the fresh air, that of an upland or mountainous character being especially beneficial. Moderation is essential in food, drink, exercise, and pursuits. In short, the scriptural injunction: "Be ye moderate in all things," applies more to patients affected with colitis than perhaps to any others.

Harrogate.

A CASE OF CONFLUENT HÆMORRHAGIC ERUPTION IN VARICELLA.

BY CHARLES R. PORTER, M.R.C.S. ENG., L.R.C.P. LOND.

THE fact that varicella is usually such a mild disease no doubt accounts for the scarcity of literature found relating to its complications. Medical advice is often not sought at all, and there is no doubt that many cases occur which are not even recognised by parents of children who have the disease. Among the uneducated if the disease is recognised it is looked upon as a harmless affection called "the blisters" and no further notice is taken of it, the child in question being probably allowed to go to school as usual. There are, however, a few authentic illustrations of the fact that varicella can assume a serious and even dangerous character from the intensity of its infection.

The following case appears to me to be worth while putting on record for the following reasons. In the first place because confluence with hæmorrhage into the vesicles is apparently so rare; secondly, because it emphasises the fact that diagnosis is made so much easier by being allowed to observe the disease from its onset; and, thirdly, because a skin lesion occurring during the incubation period seems to favour an extensive eruption—in fact, in this case it seems to have been the determining factor in the severity of the local lesions.

The patient, a girl, aged 13 years, was first seen on August 8th, 1906, and was then suffering from a somewhat irritable papular eczema of the face and the backs of both hands. The forehead, nose, and cheeks were especially irritable. She was otherwise quite well. This condition quite cleared up within two days under an application containing oxide of zinc. It should be mentioned that when an infant the patient had been unsuccessfully vaccinated three times, and when revaccinated in 1902 it was successful in two places only. The only serious acute illness previous to the present attack was acute anterior poliomyelitis when the child was aged four years, from which very slight deformity results. On August 10th in the evening she complained of headache, lassitude, and pains in the limbs and a few spots were noticed on the chest. She played tennis that evening and was somewhat restless that night On the 11th she was out and about and one or two more spots were noticed on the chest. She was restless again that night. I was called to see her on the morning of the 12th, as a rash had appeared on the face. The temperature was 101° F. and the pulse was 80. There was the typical rash of varicella present on the chest, face, and limbs, and one or two typical vesicles on the buccal mucous membrane and soft palate. The rash was in different stages of eruption, showing papule, vesicle, and crust on the chest. There were no papules at the roots of the hairs on the forehead, and the wrists, back and front, were quite clear. The patient was quite comfortable and the irritation was practically *nil*. On the 13th the temperature was 101·6° and the pulse was 80. The eruption had further developed, especially on the face, the vesicles varying in size from a pin's head to a quarter of an inch in diameter. The rash was then so plentiful on the face that it would have frequent and are often imbedded in what seems an ordinary motion. The mucus which is voided varies in appearance and consistence. It is either glairy or membranous. It may resemble raw white of egg, or it may occur as strings or shreds, or as a whitish coating on the fæces. Frequently it is seen in cylindrical masses, which are casts of the intestine—in other words, false membranes. They vary from an inch or two to two or three feet in length. But it is to be borne in mind that the mucus is frequently evacuated unrecognisable as such by an ordinary examination. For instance, a mass of it may be so coated with the fæces as to resemble an ordinary motion or it may be so incorporated with the motion as to escape detection by simple inspection. However, when it does occur in this way the motion is always sticky and adheres to the utensil. Often undigested fat is found in the fæces.

In a small percentage intestinal sand has been observed. Some of my patients have passed it in very large quantities. Sometimes the urine is changed in character. It may be high coloured or have a greenish opalescent appearance, with a strong, well-marked odour due to an increase of aromatic substances. Again, it may be light coloured and passed in large quantities. These two conditions may alternate in the same patient. Sugar is occasionally found in the urine and disappears on an amelioration of the condition of the colon. Cystitis and even pyelitis may occur as a result of colitis with bacillus coli in the urine. I have observed this in several patients and the cystitis and pyelitis disappeared with the cure of the colitis.

One peculiarity which strikes us in connexion with the secondary symptoms is their greater intensity in the membranous form of mucus secretion. The explanation is simple. It is because the glairy mucus is voided comparatively soon after it is secreted, whereas the membranous is retained sometimes for many weeks. Now during its retention it adheres closely to the walls of the intestine and entangles in its meshes the residuum of food. Often one recognises in the mucus the remains of some particular article of diet eaten two or more weeks previously, proving a prolonged retention of the mucus in the bowel. The same may be found in scybala which find an anchorage in the sacculations so frequently present in the colon in colitis. Thus there take place a retention and accumulation of putrescible matter. In the process of putrefaction which takes place products are formed which affect the colon locally and the system generally. The products of putrefaction irritate still more the already irritable mucous membrane and tend to increase the catarrh. The gases which are generated keep up the distension in the ascending and transverse portions of the colon, whilst the effect on the descending colon is generally to throw it into a more or less constant state of spasm. Both these conditions—namely, of distension and spasm—interfere with peristalsis of the bowel and cause constipation.

In connexion with the secondary symptoms apparently the only hypothesis which adequately explains them is the following. During the process of putrefaction which takes place in the colon toxins are produced. These toxins are absorbed into the system, causing an autotoxis, of which the secondary phenomena are the consequence. This view of their causation is supported by the results of treatment. The symptoms depend upon the structures involved and the amount, intensity, and nature of the toxin. The following facts illustrate this statement. There is absorption of fat, both of the subcutaneous and that usually found elsewhere. For instance, the fat in which the kidney is imbedded is often absorbed. When this happens then this organ, having lost its support, is readily displaced. In every case of freely moveable kidney which has come under my observation I have found colitis in association. Another manifestation of autotoxis is muscle poisoning, both the skeletal and involuntary muscles being involved. Hence the patient is easily fatigued by muscular exertion and there is depression of the cardiac muscle, with weakness of the circulation, causing among other symptoms cold hands and feet. Moreover, there is interference with the biliary and pancreatic functions. As a consequence of this there are oligocholia, occasionally glycosuria, and the presence of fat in the dejecta. Then the neuroses, which are some of the most troublesome features of the affection, are due to, or are influenced by, this cause. Lastly, the dull unhealthy appearance of the skin is caused by these products of putrefaction.

ETIOLOGY.

The importance of the etiology of this complaint is too evident to be dwelt upon, but the subject is too extensive to be considered fully in this paper. I shall merely state some of the causes. First, as to the predisposing causes. It has been noted by various observers that many of the patients belong to a neuro-arthritic stock. In some the arthritic diathesis is well marked, in others the neurotic tendency is more apparent. It occurs at all ages, but more often between adolescence and late middle age, though children and old people are not exempt. Women are more prone to it than men. The malady is much more frequently met with among the well-to-do classes and those who live in towns than among the artisan or labouring classes or those who live in the country. Rich diet and large quantities of animal food are powerful agents in its causation, especially amongst those who live a strenuous life in large cities. Secondly, among the exciting causes occur debilitating illnesses, severe nerve or mental strain, shock, chill, also disturbances of the upper part of the digestive tract. Combe,[1] in his excellent book on the treatment of colitis, contends that the determining cause is a bacillary infection of the mucous membrane and says that the disease is capable of being transmitted from one patient to another. He advances a strong and carefully reasoned argument in favour of his view. That bacteria play a part in the disease is morally certain, but with all deference to the opinion of this able observer I submit it is still an open question that they are the cause of it.

PROGNOSIS.

Muco-membranous colitis is essentially a chronic ailment. It is seldom fatal unless grave complications arise. Some suffer from it in a slight degree and have an exacerbation from time to time. This is especially apt to take place in the spring but it may occur after injudicious feeding, such as a series of heavy dinners. These cases by appropriate treatment soon get well. The more severe cases usually require two courses of colon irrigation with careful management after; while the very severe cases with pronounced nerve symptoms may take several years of careful management with an annual course of colon irrigation before recovery takes place. In children colitis interferes with growth and development. With them recovery takes place if they are carefully dieted, warmly clothed, and placed in healthy surroundings.

TREATMENT.

Those who have much experience of these cases know how difficult the management of them is, great patience and perseverence in treatment being required by both medical attendant and patient. At the outset of treatment we naturally eliminate any known cause, so far as this lies in our power, but sometimes we find the exciting cause is no longer in operation. Next we must adopt the best means of overcoming the stasis of the bowel and procure a regular and complete evacuation of its contents. The necessity of this is apparent, since it is the retention of mucous secretion, fæces, products of putrefaction, and microbes which causes the constitutional disturbances and increases the local irritation. Moreover, requisite means have to be taken to improve the mucous membrane and the muscular coats of the intestine. For evacuation of the bowel aperients prove unsatisfactory in colitis. They never effectually clear the bowel without producing considerable local and general disturbance, and really aggravate the condition. As they lose their power in course of time the patient requires to take larger quantities and take them more frequently, thus making the local condition increasingly worse. Probably the best means of evacuating the bowel and at the same time lessening its irritation is by colon irrigation. When this is properly administered it clears the bowel more effectually than aperients do, and instead of having a pernicious effect its action is most beneficial. A somewhat extensive experience has taught me the value of this method and that it is by far the best way to commence the treatment of colitis. It has to be carried out with very great care and under certain restrictions, as it may do harm instead of good. But properly administered its value is undoubted. The fluid used must be of a bland unirritating nature. It must also be given under a low and equable pressure or painful spasm will occur and irritation of the colon. The temperature and the quantity of the fluid are also matters of importance.

A brief description of the mode of procedure employed at Harrogate will illustrate these points. The patient reclines upon a couch, at the foot of which is placed time of other investigators by calling attention to a ce of error which may not be adequately appreciated.

---

[1] Traitement de l'Entérite Muco-membraneuse, par le Dr. A. Combe, 1905.

ome months ago I started investigating the proportions lbumin and globulins contained in pleural and ascitic ds derived from different cases of disease. The method pted was to separate the globulin fractions, known pectively as euglobulin and pseudo-globulin, by precipita- n with different degrees of saturation with ammonium sul- ate (the former being "salted out" in one-third saturated ation, the latter in one-half saturation). The precipitates re redissolved and coagulated by boiling and were then ighed. I was struck by the fact that a considerable ference was observable in the relative quantities of the o globulin fractions and of the albumin when estimations these were made in freshly drawn fluid and in the same id after it had been kept for a few days, although no signs decomposition were observable. I therefore made several timations in order to make certain of this phenomenon. e following figures are examples of the results obtained :—

—	Immediate.			Later.		
	Euglo-bulin.	Pseudo-globulin.	Albumin.	Euglo-bulin.	Pseudo-globulin.	Albumin.
scitic fluid A ...	1·1110	1·2771	1·1500	1·0850	1·3275	1·1210
" " B ...	1·2935	1·3150	1·5750	1·2400	1·6145	1·3175

here was thus in each case an increase in the amount of seudo-globulin in the fluid after standing, while the uglobulin and albumin decreased proportionately. In these xperiments the fluids were kept in the cold for three and our days respectively, without addition of antiseptics, and he figures represent grammes per 100 cubic centimetres of fluid. Several other estimations were made with similar results on fluids preserved for periods of several weeks by means of small quantities of chloroform-water, but the error of experiment was greater, rendering the actual figures unworthy of record. Possibly the action of the antiseptic caused some change. A somewhat different change was observed in the case of some serum from the slaughter-house, which was kindly put at my disposal by Mr. A. N. Leathem, bacteriologist to Charing Cross Hospital; here an increase took place in the amounts of both the globulin fractions, with a corresponding decrease in the albumin. The general effect was, however, the same—viz., an increase of the globulin present at the expense of the albumin.

On separating the different fractions by precipitation, re-dissolving them in water, and keeping them by addition of chloroform-water for some weeks, the same change was observed, but to a very minute extent compared with that in the fresh fluid. It thus seems probable that the change is due to the action of enzymes present in the original fluid, which are to a great extent destroyed or removed in the process of separation. If this be so, it is almost certain that the change in question is taking place in the effused fluid during its retention in the body, when the conditions are most favourable for the action of such substances. On this account it is that I venture to suggest that *estimation* of the albumin and globulins contained in pathological fluids, by means of the "salting out" method, is of no value, owing to the changes effected by time in the *apparent* amounts of these substances.

As to the exact nature of the change effected I cannot speak with certainty. Moll[1] considers that it is possible by the action of weak alkalies to convert albumin into globulin, and a similar action by enzymes in such fluids as I have investigated is clearly conceivable. On the other hand, Professor W. D. Halliburton, whom I consulted in the matter, points out that the change is more likely to be an alteration in solubility, not a change from one body to another, and this explanation appears much more probable. The chemical differentiation of albumin from globulin by hydrolysis and isolation of the resulting cleavage-products (globulin giving rise to glycocol, while albumin contains none of this component[2]) is unfortunately beyond my powers.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Fractures of the Odontoid Process of the Axis.

A MEETING of this society was held on May 14th, Mr. J. WARRINGTON HAWARD, the President, being in the chair.

Mr. STEPHEN PAGET read a paper, in the absence of the author Mr. E. M. CORNER, on Fractures of the Odontoid Process of the Axis. He said that the subject of fractures of the odontoid process had always been one which had been surrounded with mystery. The reason for this had been the same as in other and similar instances. The mystery was entirely due to lack of knowledge. Popularly, fracture of the odontoid process was supposed to be the lesion which resulted from the judicial execution of criminals. In a paper published in the St. Thomas's Hospital Reports, 1905, he had shown that this was not the case, but that the lesion occurred lower down in the cervical spine. In order to obtain a sure grasp of the subject a careful examination was made of all specimens which could be found in the various museums of the British Isles. After specimens and their clinical histories had been investigated the cases recorded in the literature were examined. Clinically, the result of the inquiry could be summed up as follows: there was no reason why a man should not fracture his odontoid process, as could be proved by the x rays, especially when the skiagraph could be taken through the open mouth, and recover without any spinal cord symptoms, such as paralysis or anæsthesia—in fact, with no more discomfort than that of a stiff and painful neck. It would seem that there was more danger, except in cases which had spinal symptoms, from overlooking the fracture than from the injury itself. This was the happy side of the clinical picture. The other was the penalty, instant death, which was sometimes exacted if the injury was overlooked. In fact, fractures of the odontoid process fell into line with what was the case with regard to other fractures of the upper cervical spine[1]—namely, that the subjects may have no more symptoms than a stiff and painful neck. So that it was possible to go further and generalise that all cases of injury to the neck should be skiagraphed and examined by a skilled radiographer—for it was easy for one unskilled in the interpretation of spinal skiagraphs to overlook the injury—so as to avoid the risks of overlooking a fracture.

The PRESIDENT referred to two cases of fracture of the odontoid process in which the men were able to continue work without discomfort for about five months and then suddenly developed paralytic symptoms and died. He also referred to destruction of the odontoid process by disease.

MEDICAL SOCIETY OF LONDON.

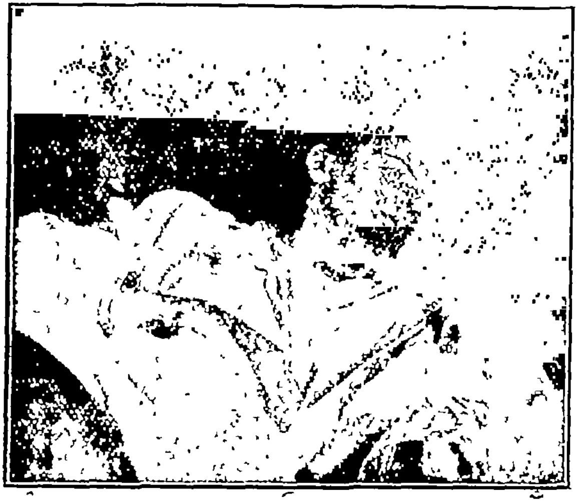
General Meeting.—Mobility of the Kidneys.—Some Heart Affections without Murmurs.

A GENERAL meeting of this society was held on May 13th, Sir EDGCOMBE VENNING, a Vice-President, being in the chair. The annual reports of the council, of the house and finance committees, and of the librarian were received and adopted. The following gentlemen were elected to hold office during the ensuing year:—President: Dr. James Kingston Fowler. Vice-Presidents: Sir John Tweedy, Sir Edgcombe Venning, Sir Lauder Brunton, and Sir Felix Semon. Treasurer: Mr. John Langton. Librarian: Dr. Arthur Francis Voelcker. Honorary Secretaries: Dr. Frederick John Poynton and Mr. Thomas Herbert Kellock. Honorary Secretary for Foreign Correspondence: Mr. H. J. Waring. Council: Mr. Robert Cozens Bailey, Mr. Charles A. Ballance, Mr. Leonard Bidwell, Dr. J. Rose Bradford, Dr. Edmund Cautley, Dr. Bertram Dawson, Dr. John H. Drysdale, Dr. Wilfred Harris, Dr. Robert Hutchison, Mr. Francis Jaffrey, Mr. Corrie Keep, Dr. C. A. S. Leggatt, Dr. Percy Lush, Dr. Joseph A. Ormerod, Dr. J. Porter Parkinson, Dr. J. S. Risien

---

[1] Transactions of the Clinical Society 1903, 1904, and 1905.

been impossible to find a free area of the size of a sixpence. The roots of the hairs were, however, still practically free, though there were, of course, many vesicles on the scalp. The chest and back were literally covered and the eruption was very plentiful on both arms and legs, back and front. The general condition was good, the patient being quite bright and cheerful and free from discomfort. On the 14th the vesicles on the face had become confluent in three places—viz., five on the forehead, three over the course of the right temporal artery on the forehead, and four on the right side of the neck over the sterno-mastoid muscle; the latter are well shown in the accompanying figure. The temperature was 101·6° and the pulse was 84. There were more crops out on the legs and arms and even on the soles of the feet and palms of the hands. One single vesicle in the left mammary region just above the left nipple had attained a diameter of half an inch (? "varicella bullosa"). The general condition was quite satisfactory, the intellect was clear, and the patient was cheerful with a fair appetite. On the 15th, after a somewhat restless night, the morning temperature was 103°. The tongue was furred but moist. The pulse was 100 and of good volume. The heart sounds were clear. The urine was of specific gravity 1020; it contained no sugar or albumin. The eruption was, if anything, more exaggerated than on the previous day. The face was swollen, especially under the eyes, and had the appearance of being inflated. Hæmorrhage had taken place into the three regions where the eruption had become confluent; the surface of the pocks in these regions being somewhat flattened but intact and the pocks were dark purplish-black in colour. The eruption was present on both pinnæ and between the toes and fingers.



The patient at this stage certainly presented an alarming appearance, but even on this day (August 15th) was quite cheerful and expressed herself as feeling "much more comfortable." The only complaint had been that the "face felt very stiff all over." Had she been seen for the first time at this stage there might have been some reasonable doubt as to the diagnosis. The following seemed to be the chief points in the differential diagnosis between variola and varicella: 1. There was an epidemic of varicella in the neighbourhood and the patient had been exposed to infection. 2. After the first day or so of the disease there were no pains or other symptoms giving rise to discomfort (such as acute pain in the back) and the intellect remained clear throughout except for occasional wandering at night. 3. The eruption came out in definite crops and the papules had never at any time the shotty feel of small-pox papules. 4. The wrists and roots of the hairs at the forehead were the only parts of the body that were particularly free from the eruption throughout. 5. The great abundance of rash present on the trunk and the character of the vesicles which never had any deeply infiltrated areola about them. 6. The absence of any prolonged period of invasion (the patient was out and about with the rash present on the chest). 7. Successful vaccination within four years. 8. The fact that 16 days after contact with the patient her sister developed typical varicella, which ran a severe course, with abundance of rash and high pyrexia. It might be mentioned in addition that there have been no cases of small-pox in the neighbourhood for the past 10 or 15 years to my knowledge.

The subsequent course of the case was quite uneventful. On August 16th the temperature fell to 99·5°, and many of the vesicles had changed to crusts. No more hæmorrhage occurred and the patient made an uninterrupted recovery. (The photograph reproduced was taken on August 16th, the sixth day of the disease.) The last scabs to come off were those into which hæmorrhage had occurred, and this took place just four weeks from the onset of the first symptoms. The local treatment employed was a mask of carbolated vaseline for the face and occasional sponging of the rest of the body and limbs with a 1 in 60 carbolic acid lotion. The room was kept darkened throughout the acute stage of the eruption. There was at no time any evidence of marks of scratching, and as the patient had had her hands bound up as a precaution and had been very carefully watched night and day the element of traumatism as a cause of the hæmorrhage could be quite excluded. It was indeed a notable fact that there was very little irritation of the face, this being mostly confined to the trunk and limbs where no hæmorrhage took place. Unfortunately there has resulted considerable scarring where the rash was confluent. It is an interesting point that keloid has developed in two places—viz., where the rash was confluent and hæmorrhagic over the right sterno-mastoid, and also where the largest pock occurred, over the left nipple.

The only references I can find to the occurrence of a hæmorrhagic eruption in varicella are: 1. in an article by Dr. J. MacCombie in Allbutt's "System of Medicine," Vol. II., p. 181, where he says: "This form is very rare [i.e., hæmorrhagic varicella, to which he is referring], and the vesicles are usually few in number. Large and small ecchymoses appear with hæmorrhages into the cutis under the vesicle, accompanied by hæmatemesis and melæna." 2. Osler in his "Principles and Practice of Medicine," p. 70, says, "Cases have been described by Andrew of hæmorrhagic varicella with cutaneous ecchymoses and bleeding from the mucous membranes." On referring to Andrew's paper in the Transactions of the Clinical Society of London, 1890, it will be found that the cases described are very similar to Dr. MacCombie's description, being complicated by hæmorrhage from the mucous membranes. Savill[1] says: "Untoward symptoms such as gangrene and hæmorrhage into the vesicles are rarely met with." With regard to cicatrices Osler says: "Indeed, cicatrices after chicken-pox are not so very uncommon. They are in my experience more common than after varioloid."

Since writing the above, further information with regard to the literature has come under my notice, viz., E. W. Goodall, in an article on varicella in the *Medical Annual* for 1907, quotes three cases, by Rundle,[2] Neech,[3] and J. D. Rolleston[4] respectively. In Rundle's case there was hæmorrhage from the mucous and cutaneous surfaces but no confluence. In Neech's case there was confluence but no hæmorrhage. In Rolleston's case there were both In the *British Medical Journal* of May 4th, 1907, p. 1051, there is an article on accidental rashes of varicella by J. D. Rolleston, to which is appended a very extensive and complete bibliography, in which the above cases are quoted.

Great Berkhamsted.

A NOTE ON THE ALBUMINOUS BODIES PRESENT IN PATHOLOGICAL EFFUSIONS.

By W. CECIL BOSANQUET, M.A., M.D. OXON., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO CHARING CROSS HOSPITAL AND TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

THE following brief note does not profess to add anythin to our knowledge of the nature and proportions of th different albuminous bodies which occur in pathologica effusions, but is written merely in the hope that it may sav

[4] Britis

Dr. HERBERT S. FRENCH and Dr. M. G. LOUISSON communicated a paper entitled "On the Extent to which Widal's Reaction persists after Recovery from Typhoid Fever." 135 patients had been traced who, whilst in Guy's Hospital with typhoid fever, had given Widal's reaction, the standard being clumping within half an hour in a dilution of 1 in 200. The test was repeated with these patients at periods after the illness varying from two months to ten years. It was concluded: 1. In 7·5 per cent. of the cases a complete reaction was obtained, in 22·5 per cent. an incomplete one, and in 70 per cent. no reaction. 2. The interval that had elapsed after the illness made comparatively little difference. It would almost seem as if the cases that persisted at all persisted perhaps indefinitely; several cases lasted eight years. 3. A complete reaction was present in 11 per cent. of the men and in none of the women. 4. Suppurative complication made it only slightly more probable that the agglutinative power would persist. 5. Age bore no relation to the likelihood of persistence.—The PRESIDENT remarked that he had found the bacilli in the bone complications of typhoid fever three years after the fever.—Dr. W. P. HERRINGHAM discussed the question of second attacks in specific fevers. This bore no relation to the severity of the first attack or to age. In measles women were more likely to suffer from a second attack than men, though the reverse held with typhoid fever. —Dr. FRENCH, in reply, said he had not examined the cases for bacilluria and it was possible that the persistence of bacilli might be correlated with the persistence of agglutinative power.

Dr. LEONARD G. GUTHRIE and Dr. W. D'ESTE EMERY communicated a paper on Precocious Obesity and Hirsuties, with Hypernephroma. The patient, a boy, aged four and three-quarter years, was 36 inches high, and weighed over four stones. There was a large general growth of hair, but the genital organs were not developed. There was marked general obesity, especially pronounced in the cheeks and mammæ. After death from pulmonary tuberculosis a hypernephroma was found on the left side; microscopically it was found to consist chiefly of necrobiotic cortical adrenal tissue; many giant cells were present. It was probably a carcinoma, although there was no infiltration or metastasis. Another case was also described which had occurred in a girl, aged three and a half years, who was 30 inches high and weighed 37 pounds. In the preceding three months she had grown an inch and gained six pounds. She measured 26 inches round the abdomen and 13 inches round the thigh. There was general obesity with pendulous mammæ. She had the appearance of a woman aged 50 years. The cheeks were bloated and blotchy. There were lineæ gravidarum on the thighs. Hair grew on the pelvis at the age of three years but the sexual organs were not developed. At the necropsy no growth was found but the adrenals were not examined microscopically. In both cases the pulse was very intermittent and the intelligence was good. The cases collected by Bulloch and Sequeira were criticised and stress was laid on the general obesity of the majority of them, nine of the cases being girls and two boys. In 12 cases the growth was on the left side, and in two on the right.—Mr. RAYMOND JOHNSON referred to a case which he had seen of a boy, aged 14 years, with enormous muscular development and hirsuties. The boy had had to shave daily since the age of ten years. A large perithelioma of the adrenal was present and slowly proved fatal.—Mr. JOHN D. MALCOLM spoke of a woman, aged 50 years, who had had a large adrenal tumour removed by operation. An overgrowth of hair had been developing for years and she had had to shave daily.—Dr. F. PARKES WEBER divided the cases into two groups: (1) those with great muscular development, and (2) those with precocious obesity. He separated the latter cases, with a bloated stretched skin, from cases of "excessive obesity." There was a case on record in a boy in whom such symptoms, including a beard, had disappeared after removal of a testicular tumour; might an adrenal tumour grow in connexion with the testicle?

LIVERPOOL MEDICAL INSTITUTION.

Nucleo-albuminuria simulating Myelopathic Albumosuria.—Intra-tracheal Injections of Izal in Bronchiolectasis.—Epidemic Cerebro-spinal Meningitis.—Renal and Ureteral Calculi and Renal Tumours.

A MEETING of this society was held on May 2nd, Mr. FRANK T. PAUL, the President, being in the chair.

Dr. T. R. BRADSHAW related the case of a lad, aged 17 years, in whom Nucleo-albumin in a large amount was mistaken for Myelopathic Albumose. The patient when seen was greatly emaciated and exhausted and died in about a week. The urine contained about 1 per 1000 of a protein body which gave a turbidity when the urine was gently warmed with acetic acid and which coagulated with hydrochloric acid. There were a remarkable deformity of the sacrum and tenderness over the upper ribs. The necropsy showed extensive matting of the intestines from tuberculous peritonitis, marked lordosis, and inflamed glands under the pectorals. The bone substance was normal. After removing the urinary salts by dialysis the protein was found to be precipitated by a trace of acetic acid and gave the other reactions of nucleo-albumin. The significance of nucleo-albuminuria was not understood.—Dr. HUBERT ARMSTRONG remarked that nucleo-albumin occurred in the urine of children with some frequency. Precipitating with acetic acid in either hot or cold solutions, nucleo-albumin was occasionally mistaken for serum-albumin when the acid was not added to the urine until after boiling. In none of the cases which he had seen could he attach any clinical significance to the presence of nucleo-albuminuria.

Mr. COLIN CAMPBELL and Dr. MASSON communicated a case of Bronchiolectasis and exhibited the patient, a male, aged 38 years. When two years of age he had a severe attack of German measles with pneumonia and when 12 years old another attack of pneumonia. After the first attack he had never been free from cough. He came under Dr. Masson's care in 1901 and was then expectorating about a pint of glairy mucus twice in the 24 hours. The physical signs were practically confined to the lower lobe of the left lung. There were marked clubbing of the fingers, typical odour, and much emaciation. For four years his condition grew worse in spite of all treatment and the patient spent the winter in bed. At the suggestion of Dr. J. Dreschfeld, who saw the patient in consultation with Dr. Masson, the patient was placed in Mr. Campbell's charge for intra-tracheal treatment. This treatment was commenced in May, 1906, and continued until December. About two and a half ounces of a 9 per cent. solution of izal in glycerine was administered daily, and by means of Mr. Campbell's revolving chair the medicament was sent directly into the diseased part. While not liking the word "cure," Mr. Campbell claimed that it looked as if the patient had been cured. He had spent the last winter at work on his farm instead of in bed, had gained 16 pounds in weight without any attempt at fattening, the clubbing of the fingers had disappeared, and there were no cough and no expectoration.—At the request of the PRESIDENT, Sir JAMES BARR examined the patient and reported that he agreed with Mr. Campbell's estimate of the effect of the treatment.

Dr. CLAUDE RUNDLE and Dr. R. STENHOUSE WILLIAMS gave a full account of a case of Cerebro-spinal Meningitis. The opsonic index was first determined on the twenty-third day of the disease and the vaccine was first administered on the twenty-seventh day and for the fifth and last time on the thirty-first day. The coccus was obtained in pure culture from the cerebro-spinal fluid on Löffler's blood serum. It stained with the usual aniline dyes and was Gram negative. As to morphology, there were cocci, diplococci, and tetrads; the adjacent surfaces of diplococci were flattened; no tendency to chain formation in liquid media was observed. Anaerobic cultures at 37° C. were negative and aerobic cultures at 20° C. were likewise negative. The behaviour of the organism was compared with that of three strains from Glasgow and one from Belfast in ascitic fluid, carbohydrate cultures at 37° C. The agglutination reactions were fully described. Dr. Rundle and Dr. Williams did not, of course, claim that the recovery of a single case was to be regarded as proof of the efficacy of the vaccine, but recovery after the patient had been almost *in extremis* and dating from the first administration of the vaccine was at least encouraging.

Mr. W. THELWALL THOMAS read a paper on Renal and Ureteral Calculi and Some Kidney Tumours. The cases of stone formed a series of 28 operated on since 1904, a large proportion being since 1905 when the x rays proved of great service in locating even tiny calculi. All the radiographs had been taken by Mr. C. Thurstan Holland. The most common symptom had been pain in the back of a dull aching character. This occurred in 17 cases, typical renal colic only occurring in nine. Colic was associated with hæmaturia and pyuria in three and with hæmaturia alone

Russell, Mr. Cuthbert S. Wallace, Mr. Charles Gordon Watson, Dr. F. Parkes Weber, and Dr. W. Essex Wynter.

An ordinary meeting of the society was then held and Dr. Hector Mackenzie read a paper on Mobility of the Kidneys. The communication was founded on the personal examination of nearly 4000 patients at St. Thomas's Hospital and the Brompton Hospital for Consumption. The condition was occasionally a cause of suffering and inconvenience or actual distress. Many cases were overlooked from various causes. The method of examining the kidneys followed by Dr. Mackenzie was described in detail. An abnormally moveable kidney was defined as one in which it was possible to get the hand completely above the upper end and to palpate the whole organ. A palpable kidney was one where, although the greater part of the organ could be felt, it was impossible to displace it so as to get above it. 2801 females of all ages were examined. Among these were 449 cases in which the kidneys were palpable and 515 in which the kidneys were moveable as defined. 1067 males of all ages were also examined. Among these were 25 cases in which the kidneys were palpable and 11 cases in which they were moveable. Thus among the female cases there were 18·4 per cent. of moveable kidneys and among the male cases only 1 per cent. Of the 526 cases of moveable kidney which were observed there was only one where the mobility existed on the left side alone. In 49 cases both kidneys were moveable. In 476 cases the right kidney only was moveable. The patients examined were suffering from a variety of complaints. Those affected with chest complaints suffered from moveable kidneys to as great an extent as those affected with dyspepsia or other disorder. It had long been supposed that child-bearing had an important influence in the production of abnormal kidney mobility but this supposition was not supported by Dr. Mackenzie's investigations. A certain degree of mobility was normal. Sex was the most important causal factor but this could not be accounted for by repeated pregnancies. As to symptomatology, out of 526 cases with definitely moveable kidney no fewer than 411 were wholly unaware of its existence. Dragging pain in the lumbar region was the most constant symptom, disappearing with rest. Dr. Mackenzie expressed considerable doubt whether moveable kidney *per se* could produce general symptoms such as neurasthenia or symptoms referable to other organs. The most efficacious treatment in severe cases was some kind of support; surgical measures were seldom advisable and were at the utmost only successful in about 57 per cent. of cases operated upon.—Dr. Victor Bonney in the main agreed with Dr. Mackenzie's conclusions. It was, however, advisable to examine the patient in the erect position. The degree of mobility was not a measure of the inconvenience likely to be suffered by the patient. In many subjects with lax abdominal walls the kidney came down by inspiration, but it would return with expiration. Much depended on the tension of the neurovascular pedicle and this would often be detected by finding the kidney in an oblique position and not finding an expiratory return. These were the two chief physical signs.—Dr. F. de Havilland Hall agreed as to the inadvisability of operation in the majority of cases. Great benefit might be derived from the feeding of these patients.—Mr. H. W. Wilson had investigated 60 cases operated on at St. Bartholomew's Hospital. Complete cure had resulted in 40 per cent. of the cases—i.e., all symptoms were relieved and the patient had remained well over a considerable period of time. After operating experimentally on cats he had found it best to decapsulate the kidney. It was better than simple fixation.—Mr. L. B. Rawling also took a more hopeful view of operation as a means of treatment. It was not necessary to remove the organ. It was essential to decapsulate the kidney and to remove the fat behind so as to give a firm attachment. It should be sewn up as high as possible close to the upper border of the twelfth rib.—Dr. S. West referred to the difficulty of diagnosis of a moveable kidney and to the advantage of examining by changes of posture. Percussion from the back was often helpful. Caution was required in advising such severe operations as those referred to.—Dr. C. M. H. Howell remarked on the usual absence of symptoms. Multiple pregnancies did not seem to have much influence in the causation. He advocated operation in acute cases or if urinary changes were present.—Mr. A. C. Butler-Smythe referred to the difficulty of diagnosis and advocated repeated examination. An accumulation of flatus was sometimes mistaken for a dislocated kidney.—Dr. Mackenzie replied.

Dr. Walter Broadbent (Brighton) read a paper on Some Heart Affections without Murmurs. He dealt chiefly with myocarditis, cloudy swelling, and fatty degeneration. In myocarditis there were an increase in the pulse-rate, rise of temperature, and some dilatation, especially of the right ventricle. In mild chorea or rheumatism it was often neglected, the patient not being sent to bed and the consequence was often a permanently damaged heart. Cloudy swelling was the commonest affection of the heart muscle, occurring in all febrile diseases; it was first studied by Stokes in 1839. The chief signs were a progressive weakening and shortening of the first sound, increased rapidity of the heart, and a disappearance of the apex beat; in bad cases the first and second sounds were often approximated. In typhoid fever were seen the most typical cases. In influenza cloudy swelling came on very rapidly and was a great danger. In diphtheria cloudy swelling quickly passed into fatty degeneration and though antitoxin had lessened this tendency it had not abolished it. Intermittence of the pulse during the febrile stage was a sign of great danger in influenza, diphtheria, and pneumonia, being usually a forerunner of acute heart failure. Dr. Sibson in 1873 first pointed out the great danger of distension of the stomach or colon to a heart weakened by fever or other disease. Pressure of a distended stomach through the diaphragm on the right ventricle often caused fatal syncope. Fatty degeneration occurred after acute illnesses, such as diphtheria, and in acute yellow atrophy of the liver, also in long diseases, such as pulmonary tuberculosis and cancer, but the most important cases were those arising in the latter half of life, some from obstruction of the coronary arteries and others without any known cause. The symptoms might be shortness of breath on exertion, faintness, præcordial pain, angina, vertigo, cardiac asthma, or epileptiform attacks with bradycardia. The pulse was short and unsustained. The apex beat was imperceptible and the heart sounds were weak, especially the first sound. Distension of the stomach or colon was a great danger in these cases also, bringing on attacks of angina or syncope and often being the cause of sudden death. In treatment Dr. Broadbent advocated a quiet life, massage in the evenings, and short courses of the iodides and strychnine alternating with other tonics.—Dr. West referred to the value of percussion as a means of diagnosing myocardial failure and to the importance of not allowing patients recovering from pyrexial conditions to leave their beds too soon.—Dr. F. J. Poynton had often found muscular failure and dilatation, without any valvular disease, in animals inoculated with the rheumatic diplococcus. He dealt with the treatment and advocated adrenalin and sodium formate.—The subject was also discussed by Dr. W. H. Willcox and by Dr. Parkes Weber; and Dr. Broadbent replied.

CLINICAL SOCIETY OF LONDON.

Gastro-enterostomy for Chronic Ulcer.—The Persistence of Widal's Reaction after Typhoid Fever.—Precocious Obesity and Hirsuties with Hypernephroma.

A meeting of this society was held on May 10th, Mr. H. H. Clutton, the President, being in the chair.

Mr. James Sherren read a paper entitled "Gastro-enterostomy for Chronic Gastric Ulcer; Healing of Ulcer Verified at Post-mortem Examination 28 Months Later." The patient, a man, aged 46 years, was admitted to the Poplar Hospital in October, 1904. He had had gastric symptoms for six years and for nine months had been in bed with severe pain which prevented him from taking solid food. An operation being performed a large ulcer was found on the lesser curvature. Posterior gastro-enterostomy being impossible on account of adhesions the anterior operation was done, with no loop. Great improvement ensued but 22 months later melancholia developed and the patient cut his throat. At the necropsy the stomach was found to be only adherent to the pancreas. The gastro-enterostomy opening admitted two fingers and the pylorus was also patent. The ulcer, examined microscopically, had healed completely. Mr. Sherren commented on the good results obtained through gastro-enterostomy, even when the ulcer was distant from the pylorus, so that excision was not the operation of choice even in such cases.—The President asked whether Mayo Robson's method of fixing the jejunum so as to make it lie from left to right had been adopted. He had used it as a routine measure for the past 18 months.—Mr. Sherren replied in the negative. He had tried Mayo Robson's method in later cases but had given it up.

the sinus back to the petrous. Considerable hæmorrhage had occurred from the sinus.—The discussion turned upon the prognosis as to recovery of hearing in those cases which recovered from the fracture.—Dr. MacBride considered that the subject was full of difficulties and that much would depend upon the amount of hearing present and the date of examination.—Dr. Urban Pritchard believed that any improvement would occur within the first three months following the injury, and Mr. Lake thought that fracture through the labyrinth must be quite incurable.

BRITISH GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on May 9th, Dr. Heywood Smith being in the chair.—Dr. A. E. Giles read a paper entitled "Observations on the Surgical Treatment of Inflammatory Diseases of the Uterine Appendages based on a Series of 120 Cases." After referring to the absence of any necessity for vindicating the justification of surgical interference in such cases, Dr. Giles presented a tabulated list of cases in which he classified them into non-suppurative and suppurative. In unilateral salpingitis the main indication for operation was pain. In bilateral non-suppurative disease the uterus was retroverted and fixed in about half the cases. Tuberculous disease was unilateral in one case out of six. When suppuration was present 16·2 per cent. of the cases were unilateral. More than half of the whole series were bilateral and were probably due to gonorrhœal infection. As a rule it was not necessary to remove the uterus because of prolonging the operation and impairing the integrity of the pelvic floor. Salpingostomy was of little value when the tubes were occluded by inflammation. In separating adhesions it was easier to work from above at first and then from below, afterwards isolating the outer extremity of the broad ligament and clamping the ovarian arteries. The uterus tended to become retroverted after removal of the tubes and therefore ought to be fixed to the abdominal wall. In tuberculous salpingitis with hydroperitoneum flushing was advised but not otherwise. Drainage was best avoided in tuberculous lesions but should be used when there was a tendency to oozing or when the bowel was damaged. In acute septic peritonitis a large rubber drain was employed, but in other conditions gauze was inserted for 48 hours when necessary. The value of Fowler's position was emphasised, aided by repeated injections of saline solution.—Dr. J. J. Macan was disappointed to find that Dr. Giles so strongly recommended abdominal drainage rather than vaginal. Instead of simple section of diseased tubes he preferred excision from the cornu of the uterus. The danger of peritonism was much less when calomel was given after the operation.—Mr. Charles Ryall had discarded suprapubic drainage for vaginal some years ago.—Mr. Smallwood Savage believed that cases of acute pyosalpinx should be treated by a vaginal incision and drainage, as in some cases so treated both tubes and ovaries would resume their normal functions.—Dr. H. M. Macnaughton-Jones agreed that hæmatosalpinx occurred apart from ectopic gestation. He urged the necessity of increasing the resistance of patients so far as possible.—Dr. R. T. Smith, Dr. W. H. Slimon, and Dr. Heywood Smith also spoke, and Dr. Giles replied.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held on May 8th, Dr. W. G. Dickinson, Vice-President, being in the chair.—Dr. Purves Stewart gave an address on the Cerebrospinal Fluid, its Diagnostic and Therapeutic Significance. After carefully explaining the details of the technique of lumbar puncture, pointing out the precautionary measures to be taken, the difficulties that might be encountered, and the manner in which they might be avoided or overcome, he described the characters of normal cerebro spinal fluid, comparing them with those found in various morbid conditions as regards the physical, chemical, bacteriological, and microscopical features, and showed the values which could be attached to the different states of the fluid for diagnostic purposes, with special reference to epidemic cerebro-spinal fever. Dr. Stewart, in dealing with the therapeutics of lumbar puncture, mentioned tuberculous meningitis, cerebral tumours, persistent tinnitus, fracture of the skull, uræmic coma, tetanus, and strychnine poisoning as illustrations of its beneficial use. The use of stovaine and adrenalin or of cocaine for the purpose of obtaining analgesia was fully entered into, Dr. Stewart expressing the opinion that spinal anæsthesia should be reserved for special cases where the use of a general anæsthetic was dangerous. The address was illustrated by lantern slides.—Mr. C. Ryall supplemented the address by giving his personal experiences of spinal analgesia in his surgical practice. He found novocaine the most efficient agent and recommended that the puncture should be made as high as the second lumbar interspace and that a portion of the spinal fluid should be withdrawn before the injection. Among other operations which he had successfully performed under such anæsthesia he instanced hysterectomy, excision of the rectum, and amputation of the thigh, each of them cases in which a general anæsthetic was contra-indicated.—Dr. Dickinson, Mr. E. Caudwell, Mr. J. Gay, Mr. Mark Robinson, and Dr. D. M. Aitken took part in the subsequent discussion.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on May 3rd, Dr. T. R. C. Whipham being in the chair.—The following were among the cases shown:—Dr. C. O. Hawthorne: Dextrocardia and Valvular Disease in a boy, aged 14 years. The cardiac dulness was on the right side and the heart's impulse below the right nipple; there was heard a systolic murmur which was conducted round the right side of the chest. A skiagram could not be obtained.—Mr. Hugh Lett showed a baby, aged seven months, with Multiple Fractures of the bones noticed at birth; skiagrams showed old fractures surrounded with callus. There were hydrocephalus and some evidence of rickets. The family history was good, but the mother had been in delicate health during pregnancy and had two bad falls during the seventh month.—Dr. F. W. Higgs showed a boy, aged three years, who while recovering from whooping-cough about two years ago, developed pain and swelling in certain joints. The lesions persisted in a subacute form and at present there was peri-arthritis of the joints of the wrists, ankles, knees, and cervical vertebræ. The spleen and glands were not enlarged. The disease was evidently toxæmic.—Mr. G. Pernet showed a case of Erythema Iris.—Dr. J. Porter Parkinson showed a case of Cerebral Tumour for which craniotomy had been performed. The optic neuritis, previously very intense, had disappeared and with it the weakness of sight, headache, vomiting, and convulsions, while the paralysis had improved in the face and arm. The tumour was probably a subcortical glioma.—Dr. D. C. L. Fitzwilliams showed a case of Multiple Exostoses in a boy, aged 10 years, on the long bones, ribs, scapulæ, and clavicles. He was the youngest of a family of seven; the mother and all her children had similar growths but had suffered no inconvenience and the growths had not increased after the first few years of life.—Mr. J. P. Lockhart Mummery showed a case of Erb's Paralysis of the Left Arm in a boy, aged three months, due to a difficult labour. Apparently the posterior cords of the brachial plexus had been ruptured, causing paralysis and electrical changes of the flexor and extensor muscles except the flexor sublimis digitorum. There were some adhesions in the shoulder-joint.

THE MIDDLESEX HOSPITAL.—The Duke of Connaught presided on May 10th at the festival dinner of the Middlesex Hospital, held at Prince's Restaurant, Piccadilly, London. His Royal Highness in the course of his remarks on the toast of the evening, "The Middlesex Hospital," said that the endowment was so poor that only 15 per cent. of their income came from invested funds. 35 per cent. came from various funds and the efforts of charitable people and the remainder was dependent on what the general public supplied. Every penny subscribed was so well spent that he believed of all hospitals the Middlesex was the most economically and efficiently managed. Lord Cheylesmore, the chairman of the hospital board, in responding to the toast, deprecated State management of hospitals; he believed if that day came it would be the worst day that could dawn for such institutions. Dr. J. Kingston Fowler and Mr. Andrew Clark also replied to the toast. Dr. Fowler said that the general public were apt to forget their indebtedness to the great general hospitals as centres of medical education, but the governors of the Middlesex Hospital had always loyally supported their medical school. The toast of "The Visitors" was submitted by Lord Derby and acknowledged by Sir T. H. Brooke-Hitching, the mayor of St. Marylebone. The Duke of Northumberland proposed the health of "The Chairman," which received a suitable response. The donation list amounted to £6500.

and pyuria alone in one case each. In seven cases pain in the back was associated with pyuria, in three with hæmaturia and pyuria, and in two with hæmaturia. Hæmaturia was the only sign in five cases and pyuria in 13 The cystoscope was of service in some cases by enabling ureteritis to be diagnosed but the important confirmatory evidence was supplied by the radiographs. The operative procedures that had been undertaken were then discussed. Seven cases of renal tumour were related and six of hypernephroma, hæmaturia being the chief symptom in all. All the tumours were removed by the lumbar incision, in one case prolonged anteriorly, the tumour weighing 5 pounds. Four of the hypernephroma patients were still quite well. In cases in which the kidney could not be made out by palpation cystoscopic examination enabled the affected side to be decided upon. A full epitome of the calculous cases had been compiled by Dr. R. E. Kelly; this was circulated amongst the members and the calculi and radiographs were exhibited.—The following gentlemen discussed the paper: the PRESIDENT, Mr. G. G. HAMILTON, Mr. THURSTAN HOLLAND, Dr. J. HILL ABRAM, Mr. RUSHTON PARKER, Mr. R. W. MURRAY, Mr. K. W. MONSARRAT, Mr. R. A. BICKERSTETH, Sir JAMES BARR, and Dr. E. T. DAVIES.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on May 3rd, Dr. J. Lindsay Steven, the President, being in the chair.—Dr. James Adam showed: 1. A patient with Atrophic Rhinitis treated by Paraffin Injection. There had been purulent discharge since childhood, with crusting, &c. Solid paraffin (melting point 45° C.) was injected in quantities of about one cubic centimetre at a time. Sandemann's sucker was used instead of massage before injection. 2. A patient with Tuberculous Lesions of the inferior turbinal, the soft palate, the pharynx, the larynx, the tongue, the cervical glands, and the metacarpal bones. Both inferior turbinal bones were thickened and the right was ulcerated. The soft palate was ulcerated and there was a small ulcer at the back of the tongue. The epiglottis was greatly thickened, as were also the ventricular bands and the arytenoids. By injections of T.R. the opsonic index was raised from 0·63 to 0·94. Lactic acid was applied to the inferior turbinals with benefit. The patient was still working. 3. A case of Chronic Adenoma of the Face. A girl, aged 22 years, suffered from scab formation at the orifice of the left nostril five years ago. A swelling started at the inner canthus of the left eye and gradually extended down to the level of the mouth and beyond the outer aspect of the eyebrow. The inferior turbinal was very greatly swollen. The crusts were removed with peroxide of hydrogen and nitrate of silver was applied. The turbinal swelling was reduced. Iodide of potassium and thyroid extract were given. The œdema disappeared in two months.—Dr. Archibald Young showed a case of Subspinous Dislocation of the Head of the Left Humerus in a girl, aged ten years. There was a history of an instrumental delivery. Neither the anatomical relations nor the radiographic findings gave countenance to a diagnosis of true congenital dislocation and the completeness of the displacement, with the now almost normal condition of all the muscles of the affected limb (except those actually stretched over the displaced head—viz., the infraspinatus and teres minor), seemed to negative the view that the displacement might be secondary to injury of the brachial plexus. The position of the arm was characteristic and the whole extremity was shortened to the extent of several centimetres, the greater part of the shortening being directly due to the displacement of the humeral head. A point of great interest in the case was the strikingly free range of movement. For example, the power of elevation was almost equal to that on the normal side. This was due to the great accommodative mobility of the whole scapula upon the trunk. The movement of external rotation of the arm and, as a complement, of supination of the forearm and hand was, however, very much limited, and it was believed that this of itself was sufficient to justify the adoption of active means to replace the head of the humerus in its normal site. Probably this could only be accomplished by an open operation, but it was thought to be fully justified. A detailed demonstration of the shoulder and of the various movements was given and a series of illustrative photographs were shown; a radiograph showing the relations of the bony skeleton of both shoulders was also exhibited.—Dr. G. A. Allan read notes on a case of Primary Cancer of a Bronchus. The tumour blocked up the left main bronchus and there were a few isolated nodules in the lungs. The pericardium was directly infiltrated. The pleura was thickened and contained a few tumour masses. The left vagus and left recurrent laryngeal nerve were pressed on. Nodules were also found in the thyroid, cervical glands, and mediastinal glands. The liver was not implicated. The tumour was a scirrhous carcinoma. The symptoms were pain in the chest and left arm, breathlessness, hoarseness, cachexia, cough, and muco-purulent expectoration. The left arm was swollen. The left pupil was contracted and there was partial ptosis of the left upper eyelid. The left vocal cord was completely paralysed. There was sweating of the right side of the head and face.—Dr. W. B. Inglis Pollock read a paper on the Relationship of Myopia to School Work. His investigations among school children showed 1·7 per cent. at five years, 8·5 per cent. at 13 years, and 25 per cent. at 18 years. Over 50 per cent. of medical students had myopia. Almost all myopia originated during school life. This was due to the yielding eye of childhood. The prevention of near sight formed a large part of school hygiene. Medical inspection had been accepted by Parliament. It was of the greatest importance that the inspection of the eyes should be carried out by specially trained oculists. This was requisite, since the fundus of the eye should be examined on admission and every second year.—The following office-bearers have been elected for the session of 1907–08:—President: Dr. J. Walker Downie. Vice-presidents: Dr. R. Barclay Ness and Dr. Joshua Ferguson. Treasurer: Dr. Alfred A. Young. Editorial secretary: Dr. J. Scott. General secretary: Dr. Archibald Young. Councillors:—Section of medicine: Dr. N. Macnair, Dr. W. Grant, Dr. John Brownlee, and Dr. Donald MacAlister. Section of surgery: Dr. J. Laurie, Dr. J. G. Connal, Dr. A. McLennan, and Dr. M. L. Taylor. Section of pathology: Dr. Leslie Buchanan, Dr. R. Bruce Young, Dr. Leonard Findlay, and Dr. John Anderson. Section of obstetrics: Dr. R. Jardine, Dr. S. J. Cameron, Dr. John Lindsay, and Dr. W. D. McFarlane, jun.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.—A meeting of this society was held on May 4th, Mr. A. E. Cumberbatch, the President, being in the chair.—Mr. A. H. Cheatle showed a series of 96 Temporal Bones exhibiting a condition which he called Infantile. The outer antral wall was thick, the mastoid process diploetic, and the compact bone increased in thickness. There were no mastoid cells. Surgically the condition was important because of the probability of disease spreading internally rather than externally, of the absence of external signs of suppuration, and the unusual forward position of the lateral sinus in these cases.—Dr. J. Donelan read notes on the Frequency of Marked Enlargement of the Pharyngeal Extremities of the Eustachian Tubes with remarks on 14 cases. Several members thought this was not such an unusual condition as had formerly been considered.—Dr. Donelan also showed a portion of the Temporal and Occipital Bones with attached Dura Mater showing an Occluded Lateral Sinus and read notes of the case.—Mr. R. Lake showed an Electric Otomasseur giving up to 18,000 vibrations a minute. In the discussion which followed the opinion was expressed by several members that otomassage was of only slight value.—Mr. C. G. Lee reported a case of Extra-dural Abscess in a patient, aged 35 years, who had had otorrhœa for 12 months. Symptoms of giddiness, vomiting, severe headache, and incoherency were present. Recovery followed a complete mastoid operation, during which it was found that the roof and posterior wall of the tympanum were absent.—Mr. Lee also read notes of a case of Chronic Otorrhœa in a child, aged ten years. After being knocked down in the school playground she complained of headache, vomiting, and pain in the right ear, followed in a few days by a rigor. At the operation there was extensive mastoid disease and suppuration round the lateral sinus, which was thrombosed. This was incised and the clot cleared out and complete recovery followed. A third case, somewhat similar to the last, following a blow on the ear terminated fatally. Here the sinus was not opened at the first operation, but two days later, owing to further symptoms, Mr. E. M. Stockdale removed nearly the whole length of the collapsed and cord-like jugular vein and much of the lateral sinus, the patient eventually dying from meningitis and pneumonia.—Dr. W. Milligan showed a Temporal Bone from a case of Fracture of the Skull. The fracture involved the middle ear and external auditory meatus, extending upwards and backwards into the occipital bone behind the lateral sinus and then through for the use of the student. The selection and mode of reproduction of the dissections are identical with those employed in the first volume—viz., multicoloured lithography, autotype (partly multicoloured), and the three-colour process. As might be expected in a work of this nature the illustrations are the most striking features and, without exception, all of them are accurate and most beautifully executed.

The digestive system is liberally dealt with in Section I. and the arrangement of the viscera according to their developmental origin should prove of great use to the student. Commencing with the oral cavity, of which there are some beautiful illustrations, the author then passes on to a description of the foregut, midgut, and hindgut. Under the last heading we notice that the portion of bowel between the termination of the sigmoid colon and the anus is simply called the rectum. Surely the modern anatomist would be justified in disagreeing with this form of nomenclature. This section also contains some very clear and instructive illustrations of the development and arrangement of the peritoneum which are well worth attention.

The second section is devoted to the respiratory system and contains many beautiful and striking drawings. The illustrations of the larynx are particularly good and their value is much enhanced by the colouring of the intrinsic and extrinsic muscles. The usual transverse and vertical sections of the thorax are given but by some oversight the numbers of the vertebræ through which the sections pass are omitted on the plates though referred to in the text. The genito-urinary system receives its full share of attention in the third section and here again the illustrations are beyond reproach. The main facts necessary for the proper understanding of the development of the uro-genital apparatus are emphasised and subsequently the various organs are fully described together with the perineal muscles and fasciæ. An excellent description of the heart and pericardium is given in the last chapter.

The book, besides being well bound, is printed on good paper and as a descriptive atlas leaves nothing to be desired.

Lehrbuch der Ohrenheilkunde für Aerzte und Studierende. (*Handbook of Otology for Physicians and Students.*) In 32 Lectures. By Dr. FRIEDRICH BEZOLD, Professor of Otology at the University of Munich. With 75 figures in the text and one table of diagrams of the tympanum. Wiesbaden: J. F. Bergmann. 1906. Pp. 346. Price 9 marks, or 9*s.*

A WORK from the pen of so renowned an otologist as Professor Bezold deserves most careful attention, for he is one of those who have striven hard to unravel the knotty questions of otology and to throw light so far as possible upon its intricate problems. The most striking feature of this book is the fact that in dealing with non-suppurative conditions of the middle ear Professor Bezold confines himself to a small number of headings of a somewhat unusual nomenclature. He speaks of obstruction of the Eustachian tube and its effects on the ear, giving to this subject only 11 pages, with three pages on simple otitis media chronica and dysacusis. He later describes otosclerosis, to which he devotes eight pages. Now this brevity alone may be somewhat surprising to those who on first taking up the book are immediately confronted with the question as to why the author has dealt so shortly with these conditions which between them include at least 60 per cent. of the cases of aural disease and entail a great amount of suffering on those afflicted by them. It is not that Professor Bezold, with all his great experience, does not feel himself able to be more explicit and more minute, but that the majority of otologists are striving to split hairs and to make subdivisions where none exist. This answer will, we think, strongly commend itself to those who earnestly seek a really rational nomenclature and subdivision of non-suppurative disease of the middle-ear. For there has been, it must be admitted, too great a tendency on the part of otologists to follow blindly in the beaten track and this must largely be due to the important rôle played by the Vienna school in otological education. The chapter on Acute Inflammation of the Middle Ear in Professor Bezold's work has, we think, an important bearing on the foregoing subject. Amongst the more important chapters in the book may be mentioned Chapter VIII. on the Tone Testing of Hearing. This should be read with great care, as embodying the views of perhaps the chief living exponent in these matters. Another very interesting portion is that on otomycosis. All the various parts of the work which are devoted to suppurative diseases are exceptionally interesting and of the very greatest merit. But the chapter which deserves the most careful reading is perhaps that on otosclerosis.

Professor Bezold's work is one which must almost of necessity be in the possession of every otologist, for although it is written as a text-book it contains so much valuable and instructive information that it is also a useful work of reference and we earnestly recommend its careful perusal to those who are interested in otology.

LIBRARY TABLE.

Invalid and Convalescent Cookery. By MARY E. BIRT. Bristol: John Wright and Co. 1907. Pp 23. Price 6*d.*—This little work will be found very useful. It gives a number of recipes for various delicate dishes. They, however, have the fault, which is obvious in so many cookery-books, of not being clearly expressed, and as cookery-books are of most use to the ignorant this is a mistake. For instance, in the recipe for bread sauce the author says that there should be taken an onion, a pinch of salt, and one or two peppercorns. This, of course, is quite right and will give the sauce a nice flavour, but then Miss Birt goes on to say that "cooks like to put in spice ...... but for invalids the sauce is better quite plain." It cannot be said that a sauce with onion and peppercorns is quite plain. We turn, as we always do in a cookery-book, to the recipe for custard pudding, and we find the following: "Beat up the yelk of an egg into a coffee-cup of milk, then add the white. Put into a well-buttered basin and steam 20 minutes." We are quite certain that this pudding made in this way would be simply abominable. If made according to directions there would be a lump of coagulated white of egg in the middle of the egg yelk and milk and the pudding would be greasy on the outside from the butter. A much better recipe would be to take half the white, to beat that with the yelk and both with the milk, to put the result into an ordinary jam-pot, and to bake the mixture in a very slow oven till it is just firmly set. Again, in the recipe for canary pudding Miss Birt says: "The weight of an egg in flour, butter, and sugar; soften the butter and mix it thoroughly all together; put into a buttered mould and boil two hours or longer." Does she, or does she not, mean that the egg is to be added to the other ingredients, for the recipe is quite uncertain on the point? And, further, what is "it"? We have pointed out these slips with no wish to find fault. Miss Birt has written an admirable little book on the whole and in the next edition we hope that she will take the opportunity of making any changes that are needful to render her meaning perfectly clear.

The Treatment of Diseases of the Digestive System. By ROBERT SAUNDBY, M.D. Edin., M.Sc. Birm., LL.D., F.R.C.P. Lond., Professor of Medicine in the University of Birmingham. London: Charles Griffin and Co., Limited. 1906. Pp. 133. Price 3*s.* net.—This little book is based on the author's experience and "is offered as a foundation upon

Reviews and Notices of Books.

The Practical Medicine Series. Vol. IX., Anatomy, Physiology, Pathology, Dictionary of New Words. Edited by W. A. Evans, M.S., M.D.; Adolph Gehrmann, M.D.; and William Healy, A.B., M.D. Series 1906. Glasgow: G. Gillies and Co. Chicago: The Year-book Publishers. Pp. 236.

This little volume, one of ten dealing with the progress made in the past year in medicine, surgery, and the allied sciences, contains short summaries of a number of monographs upon special subjects in anatomy, physiology, pathology, and bacteriology. The accounts given are in most cases sufficiently long to be intelligible and are in many cases illustrated by the authors' plates or diagrams, so that a considerable amount of valuable information is compressed within comparatively small compass. The section devoted to anatomy contains references to only five papers, an exiguous record which we hesitate to accept as a summary of the year's advance in applied anatomy. The section on physiology is also short but contains a useful *résumé* of recent work on regeneration of organs, protein nomenclature, and heart block among other subjects of practical importance. General pathology occupies the largest part of the book and contains a considerable number of references to recent research in regard to methods of diagnosis, the examination of the blood, the rôle of the spirochæta pallida in the genesis of the lesions of syphilis, and abstracts of other papers devoted to general or special pathology. A number of papers dealing with bacteriology are referred to in a separate subsection which is liberally illustrated by many good plates of spirochætæ of various kinds. The formation of antibodies and the use of antitoxic and antibacterial serums are also discussed. The book, though useful and representing a considerable amount of labour, is perhaps hardly representative of the year's advance, since there is a large preponderance of papers published in American journals or transactions. In the dictionary of new words appended to this volume in addition to words of recent origin a number of words of older standing are included. The proof-reading has evidently been very inadequately done as there are many misprints in the book. The scheme of the work is a good one and doubtless subsequent issues will improve in character and usefulness.

Les Taches de Koplik, leur Importance pour le Diagnostic et la Prophylaxie de la Rougeole. (Koplik's Spots, their Importance for the Diagnosis and Prophylaxis of Measles.) Par André Bing, Docteur en Médecine, Licencié-ès-Sciences. With one plate in colour. Paris: G. Jacques. 1905. Pp. 194.

Although it is more than ten years since the sign which bears his name was first described by Koplik, and in spite of the value which many observers in different countries have shown this sign to possess in regard to the early diagnosis and prophylaxis of measles, it has hitherto attracted very little attention in France and has been there regarded as of rare occurrence or of little value. The reason for this, according to Dr. Bing, are that the exact character of the spots have been overlooked and that they have not been distinguished from other buccal conditions superficially resembling them.

In the book before us he presents an exhaustive historical, clinical, and practical study of the condition which is both interesting and useful. The sign was described by Dr. Henry Koplik of New York in the *Archives of Pediatrics* for December, 1896, but many claims for priority of description have been made since the clinical value of the sign, so strenuously maintained by Koplik, has been generally established. All these claims Dr. Bing has carefully studied and he concludes that the most that can be said is "that it is not impossible that Flindt in 1878 and Filatow in 1895 had already seen the sign" and possibly also Bielski in 1890, but in any case he maintains that all the credit of the sign is due to the observer whose name it now bears.

In its typical and characteristic form Koplik's sign consists of a macule and a papule: the macule is a rose spot of irregular, star-like, or rounded outline; the whitish blue papule forms the central point of it and is alone the characteristic and pathognomonic constituent of the spot. It is usually only just large enough to be visible and never exceeds a diameter of one millimetre, consequently the statements often made that this central spot is from two to five or more millimetres in diameter show that other buccal eruptions are frequently mistaken for it. This papule projects slightly and can be felt with the finger; it is associated with a slightly rough or lustreless appearance ("*aspect dépoli*") of the mucous membrane, which is often of great value, since it appears quite early and persists after the actual spots have disappeared. The number of spots varies within very wide limits, being in some cases only one and in others several hundreds. After a time the rose spots tend to run together and coalesce but the white centres maintain their individuality. They are found only upon the mucous membrane of the lips and cheeks, and not, as some few authors have described, upon the gums, the soft palate, and the tongue. Dr. Bing maintains that such spots are the erythemato-pultaceous stomatitis described by Comby and not Koplik's spots; moreover, small punctiform vesicles occur upon the palate in a variety of conditions, including rubeola, scarlet fever, and influenza, as described by Koplik himself. The buccal eruption appears to go through a definite cycle which may take from two to six days to accomplish, but the disappearance is more or less abrupt since the small white spots become easily detachable and are removed by the buccal secretions, while ulceration never occurs. The diagnosis and the nature of the sign are carefully described and exhaustively discussed by Dr. Bing who then details his own observations. He concludes that the sign is pathognomonic of measles but that its absence does not prove that the patient is not suffering from that disease. With regard to the time of its appearance, he finds that it may appear from one to five days before the eruption but most often two days before; it reaches its maximum on the day on which the rash first appears on the face, commences to disappear on the full efflorescence of the rash, and does so completely from the second to the fifth day of the eruptive stage. He further considers the value of the sign in diagnosis and after an exhaustive study of the conditions likely to be mistaken for measles arrives at the conclusions that it is a sign of the utmost value and that in every case of illness in a child it should be sought, since it enables isolation to be carried out sooner than would be possible otherwise. The character of the spots has no bearing upon prognosis or on the severity of the attack. Dr. Bing's book concludes with a bibliography of 234 references and is a valuable study of the condition which we can cordially commend.

Atlas and Text-Book of Human Anatomy. Vol. II. By Professor J. Sobotta of Würzburg. Edited, with additions, by J. Playfair McMurrich, A.M., Ph.D., Professor of Anatomy at the University of Michigan. Quarto, pp. 194. London and Philadelphia: W. B. Saunders Company. 1906. Price 25*s.* net.

The second volume of this Atlas and Text-Book of Human Anatomy is the immediate continuation of the first and treats of the viscera and the heart. Professor Sobotta has considered it advisable to include the heart with the viscera since it is usually dissected in common with them and consequently this arrangement makes the atlas more convenient flies and other insects and ticks of considerable use. There are a contribution on a case of Distomiasis of the Liver and Rectum by Dr. Edward Cuffey and Some Observations on the Presence of *Spirochæta Duttoni* in the Ova of *Ornithodorus Moubata* by Captain R. Markham Carter, I.M.S. A short note at the end of the number states that some good results have been obtained in trypanosomiasis by following the treatment with atoxyl, discovered by Thomas and Breinl, with small doses of bichloride of mercury. The communication is made in the hope of inducing those who have opportunities of treating patients to give this method a trial.

The West London Medical Journal.—The April number of this journal contains an interesting article by Dr. F. G. Crookshank on the Prognosis and Treatment of Diphtheria. Among other advice we may note the counsel not to wait for the result of a bacteriological examination in a doubtful case but to give antitoxin at once, to avoid meat juices and essences out of tins and bottles, and to adopt tracheotomy rather than intubation in private cases. Mr. Stephen Paget writes on throat and nose cases in general practice, noting "that people nowadays of all classes, rich and poor alike, think and worry more over their noses than they did twenty years ago." Mr. John R. Lunn records a case of retroversion of a gravid uterus which simulated extra-uterine pregnancy.

The Birmingham Medical Review.—In the March number a paper on the Selection of Cases of Pulmonary Tuberculosis for Sanatorium Treatment, by Dr. J. Douglas Stanley, deals chiefly with the difficulties of early diagnosis; the author does not appear to hold that much assistance is to be expected in this from the use of x-rays. This issue contains also the conclusion of Mr. W. Edward Bennett's article on Results of Operation for Congenital Dislocation of the Hip, and a useful paper by Mr. William Billington on After-Treatment of Cases of Abdominal Section; the use of calomel is advised for intestinal distension, and good results are recorded from continuous irrigation of the rectum combined with drainage of the peritoneal cavity by a tube placed in the recto-vesical pouch, the peritoneum thus possibly becoming an excreting instead of an absorbing structure.

ASYLUM REPORTS.

St. Andrew's Hospital for Mental Diseases, Northampton (Report for the Year 1906).—During the year 1906 there were 91 admissions (35 males and 56 females), which is 13 more than in 1905. The average number resident was 410 (185 males and 225 females), being the same as that of the previous year. The discharges numbered 61 (18 males and 43 females), and of these 22 (seven males and 15 females) were discharged recovered, 11 (four males and seven females) relieved, and 28 (seven males and 21 females) "not improved." Touching on the subject of "recoveries," the committee of management states: "There has been a decrease of 24 in the number of recoveries. This is accounted for chiefly by the fact that every year the hospital gets more crowded with incurable cases, and steps are being now taken to remedy *this* by discharging from time to time incurable cases to make room for those who may derive some benefit from treatment, as suggested by the Commissioners in Lunacy in a former report." The percentage of recoveries on the total number of admissions during the year has been 20·0 for males and 26·28 for females, giving a total of 24·17, which is very low for an institution of this importance. 20 deaths (12 males and eight females) occurred during the year, and five of these (males) were cases of general paralysis. The numbers remaining on the books of the hospital on Dec. 31st, 1906, were 187 males and 225 females, making a total of 412. This number includes one voluntary boarder. This paucity of voluntary boarders would seem to indicate that patients are not encouraged to enter the hospital in this capacity. Mr. J. Bayley reports that there were no cases of infectious disease, serious accident, or suicide during the year. No balance-sheet is published with the report, but the committee of management states that the financial state of the hospital during the year has been very satisfactory—the income from patients being the largest since the institution was founded. The committee also states that during 1906 the number of patients who were assisted in their payments has been 77, of whom 36 belonged to the county of Northampton and 41 were out-county cases. The amount of assistance rendered to make up the payments to the lowest rates ordinarily charged was: county cases, £1944; and out-county cases, £1290; being £134 less than the previous year. The result of the working of the farm at Moulton Park for the past year has been most satisfactory, there being a favourable balance at the end of the year of £692.

Looking Back.

FROM

THE LANCET, *FRIDAY*, May 15th, 1829.[1]

ON THE USE OF TINCTURE OF HYOSCIAMUS, IN SCARLET FEVER.

By HENRY REES, *Esq.*, M.R.C.S.

HAVING read, in the last Number of THE LANCET,[2] Hufeland's observations on the use of belladonna in scarlet fever, I am induced to recommend to the notice of the profession a medicine which I have found highly serviceable in the same disease, and which may probably operate on the same principle—I mean the tincture of hyoscyamus. As surgeon to the "City Institution for Diseases of Children," I have had between two and three hundred cases of scarlet fever under my care, few of which have proved fatal. If not trespassing too much on your valuable pages, I will briefly describe the practice I pursue. In milder cases, I recommend leeches to be occasionally applied to the head, prescribe small and repeated doses of calomel and antimony, with gentle laxatives, (a mode of treatment proper in all exanthematous diseases,) and every two or three hours some of the liq. ammon. acetat. mixture, with small doses of ipecacuanha, and the t. hyoscyami. In severer cases, I apply leeches freely and frequently to the head and throat, administering the same medicines. My attention is chiefly directed to allaying the nervous irritability and excitement, for in proportion to such irritability and excitement, are the subsequent exhaustion and degree of danger. Opium is, in some cases, a valuable medicine. The prussic acid I have never tried, but should anticipate much good from its effects. Cold ablution is proper, especially when agreeable to the sensations of the patient. I prefer partial to general ablution, having seen two or three instances, and heard of others, in which fatal symptoms appear to have arisen from the excessive chill the system had sustained. As a *stimulant* in the stage of collapse, if I may be allowed the term, I find ammonia most useful.

The effect of medicines, the progress of the disease, and the appropriate measures, are indicated by the appearances of the tongue; should the tongue continue unchangeably parched, the disease will terminate fatally; immediately it *begins* to be moist, the calomel and antimony should be omitted, or salivation will be induced. In scarlet fever, as in all other diseases in which the tongue is dry and red, Epsom salts are injurious, though frequently prescribed; so are also the drastic purgatives, and, what are sometimes named, the "tonic-evacuants." The tongue, indeed, in most *diseases, is* my principal guide. On this subject I could say much, were I not fearful of extending these remarks to too great length.

45, Finsbury Square, May 4, 1829.

---

[1] It will be noticed that this particular number of THE LANCET is dated Friday, May 15th, 1829, instead of Saturday, May 16th, 1829. We are at a loss to decide whether this was accidental or intentional but it may have been caused by the desire of the Editor to place in the hands of his readers that morning an accurate copy of the "Unlawful Disinterment and School of Anatomy Bill," the consideration of which had been postponed after repeated delays to that evening. The style of dating was not repeated in subsequent numbers so far as we have checked them.

[2] Vide "Looking Back" in THE LANCET, May 4, 1907.

which each reader may raise a more imposing superstructure." The introduction extends to one-third of the volume and a great deal that is valuable in the treatment of digestive disorders is considered in it. For the determination of the size and position of the stomach Dr. Saundby recommends larger powders than those often employed. We observe that arsenic is not to be found among the drugs recommended in the treatment of gastralgia. The section on the Indications for Operative Interference in Diseases of the Stomach will be a useful guide to the practitioner and will help him to give sound advice to his patients. The book is well and clearly written and is a practical guide to the subject of which it treats, the text being followed by a list of very useful formulæ. It is published at a moderate price.

The World's Classics. Vol. cxli., Edmund Burke's Writings and Speeches (vol. iv.), with an introduction by F. W. RAFFETY; vol. cxxiv., The Works of William Hazlitt (vol. v.) Lectures on the English Comic Writers, with an introduction by R. BRIMLEY JOHNSON; vols. cxxv. and cxxvi., The Works of Thomas Carlyle (vols. iii. and iv.), The French Revolution; vol. cxxxiii., Palgrave's Golden Treasury with Additional Poems. Henry Frowde, Oxford University Press. Price 1*s*. each net, bound in cloth, and in other bindings up to 5*s*. 6*d*. each net.—It was just over a month from the present time of writing that we reviewed a batch of these cheap and handy volumes, and now another five lie before us. If their rate of production is an index of the public demand for them we rejoice that the provision of such excellent literature at a merely nominal price may well be checking the inordinate consumption of worthless and ephemeral printed matter that bids fair to sap the spring of national taste in letters. Three of the present volumes deal with the French Revolution, two of them containing the immortal prose epic of Carlyle, which to praise now would be indeed to gild refined gold, and the third the more neglected writings of Edmund Burke on the first phase of that stupendous national drama. These are "Reflections on the Revolution in France, 1790," "A Letter to a Member of the National Assembly, 1791," and "Thoughts on French Affairs, 1791," of which we can say no more terse and accurate thing than is written in Mr. Raffety's preface to this edition: that although in this cause the verdict of history is against his reactionary pleading yet readers of it are forced to feel with Hazlitt that in arriving at one error he discovered a hundred truths. The lectures of this latter essayist on The English Comic Writers form the next volume; they cover a large number of the English classical authors, including, *mirabile dictu*, Dr. Johnson. They display a very keen and correct analytical faculty, but in reading them it is hard to repress a comparison with the contemporary critical work of Lamb, a contrast entirely in favour of the sweet and great-hearted nature that glows in every page of "Elia." "The Golden Treasury" of Palgrave, with additional poems, is the last book of this batch. It is late in the day to express our regard for an anthology which has formed the basis of nearly all subsequent collections of English general poetry—an anthology that spun a chain of gold from Shakespeare and Drayton to Shelley and Wordsworth. But we are inclined to cavil at the policy of binding up more recent poetry with this volume. The poems added are not the collection in the "Golden Treasury" second series, and we should have preferred to see an original nineteenth century anthology issued in a separate volume by the present publishers. The poems as they stand are not adequately representative; thus although they include such gems as a dozen of Tennyson's songs, "A Grammarian's Funeral," "Porphyria's Lover," "The Chambered Nautilus," "The Blessed Damsel," Henley's "Invictus," and several poems of Matthew Arnold, the last-named is not represented by "The Scholar Gipsy," "The Forsaken Merman," or "Rugby Chapel," and although the first version of Fitzgerald's "Omar" is included, and, later, there are several of Kingsley's poems, there is no line of Swinburne—a truly surprising omission.

JOURNALS AND MAGAZINES.

Folia Therapeutica.—The second number, dated April, 1907, of this quarterly of modern therapeutics and pharmacology fulfils the promise of its predecessor. An introductory Berlin letter from Professor C. A. Ewald gives a *résumé* of Ehrlich's recent researches on the lethal action of various aniline dyes on trypanosomes. Sir James Sawyer in a paper on "Fuming Inhalations in Asthma" pleads for the replacement of quack preparations of this nature by properly prescribed powders and gives several formulæ which he has found useful in dealing with spasmodic bronchial attacks. The longest article is a clinical lecture by Professor H. Senator of Berlin, "On the Causes and Treatment of Arterio-sclerosis," in which he advocates the "lacto-vegetarian" diet, and for drugs the iodides and nitrites in combination. He refers to the method of treatment by solutions of salts in quantities closely imitating those of the blood serum but does not speak positively on their value; he recommends giving the iodine as iodipin, and the use of this preparation in tertiary syphilis is the subject of the following article by Dr. G. G. S. Taylor and Dr. R. W. Mackenna of Liverpool, who speak highly of its efficacy in skin syphilides when given in full doses by the mouth. Dr. Arnold J. Edwards writes on Recent Therapeutical Advances in the Treatment of Gonorrhœa in the Male and advocates the local use of protargol. A contribution by Dr. V. Schnieden on the Theory and Application of the Hyperæmia Treatment of Bier might with advantage have been a good deal fuller as it deals with a subject of growing importance and one which deserves the general attention of the medical profession; it has a wide field of application and is easily put into practice. Dr. Schnieden advises the study of Bier's own book on the subject. Dr. Frank H. Barendt recommends eugallol, *inter alia*, in the treatment of psoriasis. Dr. Karl A. Grossmann has a paper on Dionine in Ophthalmic Practice. He has found this remedy valuable in various forms of keratitis, conjunctivitis, and other diseases. The last paper is a short note by Professor L. Brieger of Berlin on the Hydrotherapeutic Treatment of a few Constitutional Diseases, and the folia end with abstracts from various articles on therapeutics, amongst which is a laudatory notice of Kuhn's suction-mask for the production of passive hyperæmia of the lungs.

Annals of Tropical Medicine and Parasitology. Vol. I. No. 1. Liverpool School of Tropical Medicine.—Hitherto the work done in the Liverpool School of Tropical Medicine has been published in the form of memoirs, of which 21 have been issued. This has naturally limited the matter to the work done by the members of the staff and it was apparently felt that a journal in which work from other sources might be published would be more generally useful. It is for this reason that the "Annals of Tropical Medicine and Parasitology" has been instituted, the editors of which state that they are prepared to consider contributions from outside the school. This is a step in the right direction and will tend to facilitate the spread of knowledge with regard to the most recent work in the subjects dealt with. The first number of the annals consists largely of morphological descriptions of various insects and other arthropoda collected in the Congo Free State during the expedition of the Liverpool School of Tropical Medicine to the Congo in 1903–05. Medical men on the West Coast or in the neighbourhood of the Congo will find the observations and map of the distribution of various species of tsetse

DOUGLAS POWELL and Dr. TAYLOR. In their memorandum the work of LISTER and of PASTEUR and its enormous beneficial influence was commented upon, and particular instances were related in which bacteriological investigation has led to the improved treatment of disease. The nature and treatment of cretinism and myxœdema were also cited as valuable discoveries directly resulting from experimentation upon animals. Apart from the hard logic of facts which these witnesses brought to bear upon the question of vivisection, the concluding words of Sir RICHARD DOUGLAS POWELL'S evidence might be read with great advantage by those people who, carried away by sympathy with the dumb animal, overlook the sufferings of their fellow creatures. It is hard for them to realise, the President of the Royal College of Physicians showed, the intense longing for greater power over disease which possesses the medical man whose hours, whose days, and whose weeks are spent in the observation of suffering with which he is often able but partially to cope; to see, perhaps, a beloved child dying day by day, and to witness the harrowing distress of mind of the parents, is to feel that for the prevention of such misery as that even a hundred dogs might be sacrificed without blame. It is but just that the influence of sentiment should be evoked on one side when it plays so large a part upon the other. The anti-vivisectionist relies, as any calm perusal of the evidence given by Miss KENEALY and Mr. GRAHAM will determine, to no small extent upon purely sentimental considerations. Such considerations we are far from belittling, and we would have it recognised that in this matter true sentiment has as much argument to proffer in favour of, as against, the practice of careful experiment upon living animals. It is the biased sentiment that we deprecate which misrepresents facts, which maligns honest observers because they are scientific, and which ignores advantages because they are reached by the hated means. We sympathise, as we believe every man of science sympathises, with the humane affections which underlie the words and the actions of the anti-vivisectionist, but we appeal to him not to let the promptings of a kind heart lead to the indications of a weak head. Let him show not merely that he can sympathise with animals, but also that he can understand and appreciate the arguments of men when they demonstrate the widely beneficial influences of properly controlled experimentation upon living creatures.

The Registrar-General's Annual Summary.

THE Registrar-General's Annual Summary of Births, Deaths, and Causes of Death for 1906 has made its appearance this week, and we wish to congratulate the office upon its promptitude. We notice in the summary considerable improvements on the issues of previous years and to these we desire briefly to direct the attention of our readers. In submitting to the President of the Local Government Board the fifty-third issue of this summary the Registrar-General takes occasion to give an account of the scope and growth of the publication, and, incidentally, of the origin of vital statistics in London and other large towns. The earliest records which we possess of London mortality appear, according to Captain GRAUNT, to have begun towards the end of the sixteenth century. We learn, on the authority of Dr. WILLIAM OGLE, that these records, originally styled "The London Bills of Mortality," were compiled through the agency of the Company of Parish Clerks, and, as the main object was to give information concerning the progress of the plague which at that time was prevalent in London, this publication was discontinued with the cessation of that disease. From the beginning of the seventeenth down to the middle of the nineteenth century the old bills of mortality were published regularly, but in 1849 the bills of the old parish clerks came to an end, having been superseded in 1840 by the new bills published under the authority of the Registrar-General, which had relation to a much more extended area.

The first of the long series of annual summaries issued from the General Register Office during the last 52 years consisted of a pamphlet of only eight pages, which was issued by Major GRAHAM, the first Registrar-General, in the year 1855. Ten years after the first issue—viz., in 1865—particulars of births and deaths were added for seven large English towns, as well as for Edinburgh, Glasgow, and Dublin. The vital statistics of Vienna were also included for the first time in the annual summary for that year. In 1872 the list was extended so as to include 67 provincial towns and 11 foreign cities; and ten years later it was further extended to 78 towns and 30 foreign cities; while the present issue relates to London and to no fewer than 217 provincial towns and 38 colonial or foreign cities. So much for the expansion of the summary from a pamphlet of eight pages in 1855 to one of 76 pages with an excellent chart and complementary tables in 1906. But Sir WILLIAM DUNBAR tells us in his preface that the recent development of the science of vital statistics has necessitated a revision of the methods of calculation that passed muster in earlier years. Thus, we learn that for the present summary not only have the simple ratios of births, deaths, and marriages been presented in terms of the living at all ages but special estimates of particular sections of the population have been made for the purpose of expressing marriage-rates in proportion to the number of marriageable persons in the community, birth-rates in proportion to the number of women of child-bearing ages, and death-rates based on a standard population of the same age and sex constitution as that of the country generally. Having regard to the great and increasing public interest now shown in the important question of infantile mortality, the subject has been considered in reference to climatic conditions and an endeavour has been made to differentiate the deaths due to antenatal influences. Lastly, and to this point we attach considerable importance, the Registrar-General tells us that in order to furnish the earliest available information concerning mortality the data, as returned by the registrars, are now published in the annual summary; and although the details may require revision and some modification before their final presentation in the annual report, nevertheless in their provisional form they are now available to the public nine months earlier than in former years.

Turning to the vital statistics of 1906 we find that the marriage rate of England and Wales in that year, although

THE LANCET.

LONDON: SATURDAY, MAY 18, 1907.

The Royal Commission on Vivisection.

THE Royal Commission on Vivisection has issued its second report consisting of the minutes of the evidence taken during the months of February and March, 1907. The following are the names of the witnesses whose evidence is contained in the minutes:—Mr. W. H. POWER, C.B., F.R.S., principal medical officer to the Local Government Board, representing the Local Government Board; Dr. A. R. CUSHNY, F.R.S., professor of pharmacology and materia medica in University College, London, representing the committee of medical and scientific societies; Lord RAYLEIGH, O.M., President of the Royal Society, and Sir R. DOUGLAS POWELL, Bart., K.C.V.O., President of the Royal College of Physicians of London, representing their respective bodies; Dr. FREDERICK TAYLOR, senior physician to Guy's Hospital; and Mr. J. W. GRAHAM, principal of Dalton Hall, Victoria University, Manchester, and Miss A. KENEALY, L.R.C.P. Irel., representing the Parliamentary Association for the Abolition of Vivisection.

The evidence contained in this report may be read with much satisfaction by fair-minded and humane persons. They will be well satisfied, we think, that the safeguards which in this country are erected against needless infliction of pain on lower animals are both sufficient and efficient. The evidence given, for example, by Mr. POWER, which demonstrates exactly the position of the Local Government Board in the matter of vivisection, shows indubitably the necessity for animal experiments in the public interest, while bringing out the fact that such experiment in the case of investigations required by the Local Government Board consisted of nothing more formidable than a prick in something like 98 per cent. of the cases. The principal medical officer of the Local Government Board quoted an explanatory minute from the pen of the late Sir JOHN SIMON and showed that in order to increase our power to prevent various diseases of men and of domestic animals a first aim is to obtain exact scientific knowledge of the causes and of the mode of attack of the diseases in question. In this sort of study more or less experiment may be necessary to determine the results which the administration of a particular reagent will produce upon an animal. Moreover, in aid of preventive medicine, and often in aid of therapeutics, experiments on animals are needed to test the value of alleged prophylactics and remedies as against known causes or processes of disease. Sometimes, as in the case of Asiatic cholera, such experiments are more immediately in the interest of man, sometimes, as in the cases of sheep-pox and cattle plague, they are more in the interest of domestic animals. Sir JOHN SIMON stated that while no doubt pain or uneasiness will afterwards arise in cases where disease is the result of experiment, yet the experiment would often require that the animal should be killed as soon as disease became manifest and, "of course, no animal would needlessly be let live in a state of suffering." The memorandum of its first medical officer is still adhered to by the Board. The Local Government Board sends to each experimental worker on each occasion of his engagement by the Board to do a piece of work a note drawing his attention to the fact that no experiments on living animals are to be conducted at the cost of the State without the employment of anæsthetics in the case of painful operations nor without a report from time to time explaining the object of such experiments and showing their necessity for the purpose of discovery. The men who perform these experiments are, of course, certificated workers under the supervision of the Home Office and at any time their procedure may be inspected. The questions directed to Mr. POWER brought out in answer an account of work done in connexion with the prevention or cure of diphtheria, cholera, plague, and typhoid fever in particular. They showed, further, that through her international obligations with regard to the entry of disease by ships England is bound to employ experimental investigation to insure prompt and certain detection of infectious diseases. In the same way inoculation experiments often become essential for the local investigation by medical inspectors of the Board of conditions under which disease exceptionally prevails, as, for instance, at the present time in the case of cerebro-spinal meningitis. The substantial benefits with regard to curative treatment of disease that may be obtained from experimental work are shown better perhaps in the case of diphtheria than of any other disorder. The facts of the case before and after the introduction of antitoxin are clearly stated by Mr. POWER and became the more convincing the more they were scrutinised by his interrogators. In the hospitals of the Metropolitan Asylums Board the case mortality has been reduced from a rate of 40 to one of 12 per cent., and Mr. POWER was able to uphold the validity of these figures and to show that no extraneous circumstance interferes with the favourable light which they throw upon the value of diphtheria antitoxin. The evidence of Dr. CUSHNY was directed to an explanation of the influence which experimental methods in pharmacology have exercised upon therapeutics, and similarly is of great public interest. The case of digitalis was one of the most striking which he cited in support of his view of the value of experiment. This drug was formerly supposed to have a slowing and weakening action upon the heart and was in use for such conditions as aneurysm. It was the experimental work of TRAUBE and LAUDER BRUNTON which demonstrated the real action of digitalis and saved many scores of patients from the baleful results of its use under false premisses. The introduction into practice of chloral, purely the result of LIEBREICH'S experimental work, was another instance quoted by Dr. CUSHNY to show the value to therapeutics of such investigations, and he dealt also with other important members of the soporific class of drugs and with the modern antipyretics.

The opinion of the medical profession generally upon the question of vivisection was represented by Sir RICHARD

Annotations.

"Ne quid nimis."

THE PUBLIC HOUSE TRUST MOVEMENT.

THE English public has not unnaturally come to regard the word "Trust" as a synonym for commercial immorality and many people may turn in horror from the bare mention of such a title as "The Public House Trust Association," but the man who does so must needs be in complete ignorance of the good that this Trust may bring to the nation if it is able to expand properly its efforts in a cause which every friend of true temperance must have at heart. The sixth annual report of the Central Public House Trust Association lies before us and we desire to place prominently before our readers the excellent motives of this movement and the no less excellent results that it has already produced. The object is to promote temperance by removing from the retail sale of alcoholic beverages all element of private profit and the means adopted are the acquisition of public-houses in which managers are employed and paid a fixed salary, to which is added a commission on the sale of food and non-alcoholic beverages only; a prominent feature is that all articles of food and drink are of the most wholesome quality obtainable and the houses are made clean, comfortable, and orderly; in fact, they are to be transformed from mere drinking-shops into inns in the best sense of the word; some of the bigger houses, of which more than 230 are already under trust management, offer decent lodging accommodation and recreation-rooms for workmen, besides providing them with wholesome food and drink, and they have been eminently successful in increasing the sobriety in certain neighbourhoods. The means by which these houses are to be acquired are the formation of "a Public House Trust Company in each county under the direction of local gentlemen of public spirit. The maximum dividend payable to the shareholders is 5 per cent.; surplus profits are devoted to the benefit of the public and, where possible, to the provision of counter-attractions to the public-house. The trust companies rent or purchase existing public-houses and also, wherever the magistrates decide that it is necessary to create new licences, will apply for them on public grounds." The association has made rapid progress in six years and has now 38 incorporated trust companies in the British Isles. A memorial has recently been presented to the Prime Minister, signed by a very representative body of supporters, which includes many bishops, lords lieutenants of counties, members of both Houses of Parliament, chairmen of licensing sessions and other magistrates, and mayors, appealing for the inclusion of the objects of the association in the Licensing Bill which is under the consideration of the Government. A statutory provision of trust companies would seem to be necessary for the full development of the scheme, for a perusal of this report shows that as private companies they have to make difficult headway against such strongly established interests as are vested in the "tied" system of public-house tenure which prevails almost exclusively in many counties.

THE DISPENSARY QUESTION AT COVENTRY.

TEN years ago the dispensary question at Coventry was an acute one, and we foretold in these columns that the relations of the Coventry Provident Dispensary with the medical staff of the institution would not be maintained long in view of better knowledge of the real meaning to the medical profession of the conditions of contract practice. In an article published in our issue of April 6th we mentioned that five out of seven of the medical men attached to the dispensary had sent in their resignations, that the resignations had been accepted, and that the medical men who were leaving the dispensary were starting a medical club to be managed on proper professional lines. The committee of the Provident Dispensary has issued a circular to the members of the dispensary in which it implies that under the new medical service, which certain of the seceding medical men propose to establish, the supply of drugs will be inferior to that of the dispensary. We quote the paragraph of the circular from the *Coventry Daily News*:—

> In the matter of drugs, it will be specially necessary for the members to deliberately consider to what extent they may be called upon to make sacrifices in withdrawing from the Dispensary. Under the rule as now established, the drugs are provided from a fund separate altogether from that from which the doctors receive their stipends, and, consequently, the drugs given, however expensive, make no difference to the amount received by the doctor prescribing them, but under the new system put forward to take the place of the Dispensary, every item saved will go into the pockets of the medical men constituting the new service. It will therefore be seen that if during any year a very large amount were saved upon drugs, which is quite possible, this would be a consideration which, under the circumstances, could not be overlooked. The members of the Dispensary may be absolutely certain that their committee will maintain their policy of seeing that whatever drugs are necessary will be provided without regard to expense. The institution has always enjoyed the highest reputation and the fullest confidence of the members for the excellence of the medicines supplied.

That it should be possible for the members of a managing committee to make such accusations against a group of professional men with whom they have recently been associated will be an additional reason to medical men for having nothing to do with the Coventry Provident Dispensary. The circular says also that "The committee have pleasure in informing the members that medical men with good qualifications have already placed their services at their disposal and they will at an early date notify the members of the arrangements made." We are making an inquiry on the spot and our commissioner's report of the position will appear shortly.

THE CITY AMBULANCE SERVICE.

BY kind permission of the Commissioner of Police for the City of London we have been enabled to inspect the first motor-ambulance provided by the City, which is at present accommodated within the precincts of St. Bartholomew's Hospital. Past experience has shown that when the City undertakes a public service it carries it out in the most efficient manner possible, and in this case it has adopted its usual wise course: the ambulance equipment which it has provided could hardly be made more perfect. It consists of a handsomely appointed vehicle, British built and fitted with an 8 h.p. electric power engine, the cells for driving it being charged from dynamos at the ambulance station. The wagon is fitted with two canvas stretchers, one above the other, which slide in and out on runners, the top one being supported on an ingeniously hinged bracket which permits of it being lowered to a convenient level for removal. On the other side of the car is a long locker seat for the attendant, which could, if necessary, accommodate a third patient. A lavish provision of first-aid requisites is made, including splints of all kinds, with spare paddings, dressings of gauze, lint, and wool, each done up separately in a hermetically sealed package, bandages of different materials, and some simple drugs and instruments; the aim has evidently been to supply anything that could be required by a medical man who might be summoned to a case, for the attendant constable, even though a holder of the St. John badge, as are all the City police, would hardly require to know the use of everything provided; in fact, no conceivable form of accident has been overlooked in the equipment. The car runs smoothly and is hung on comfortable springs; it has ground-glass windows and efficient ventilators, and its outside is enamelled white and blazoned with the City arms and the ambulance cross. In connection slightly above that of the preceding year, was nevertheless in defect of the average rate in the ten years 1896–1905. The rate of birth was the lowest on record; it was below the rate of the previous year by 2 per 10,000 living, and was below the decennial average rate by 17 per 10,000. The death-rate, although higher than that of 1905 by 2 per 10,000, was nevertheless below the average in the preceding ten years by 14 per 10,000 of the population. Infantile mortality, measured by the proportion of deaths under one year to registered births, was 133 per 1000, which is 5 per 1000 above the rate of the preceding year, but as compared with the average in the preceding decennium the rate of 1906 showed a decrease of 14 per 1000 births.

Mediterranean or Malta Fever.

DURING the last quarter of a century few if any of the departments of medicine have attained greater triumphs than that dealing with tropical diseases, for in this period we have witnessed discoveries in the etiology of these diseases in which men of science from nearly every country have had their share. We need only mention the famous researches of Professor KOCH on cholera and the valuable and life-saving facts resulting from the discoveries of LAVERAN, MANSON, and ROSS in malaria. Light has been thrown upon the causation of yellow fever by our professional brethren in America, while at last the pathology of sleeping sickness has been demonstrated by the Schools of Tropical Medicine of London and Liverpool. That curious disease, kala-azar, has been the subject of three separate Commissions appointed by the Government of India and its etiology seems to have been determined; and now the question of the causation of Mediterranean fever has been settled by the researches of a Commission appointed by the Royal Society.

Mediterranean or Malta fever has for a long time been a subject of discussion in medical science. The disease was first of all described by Dr. WOODWARD; his account was based on his experience whilst serving in the Federal army of the Potomac in 1861, and he considered it to be a hybrid affection—a combination of malaria and typhoid fever. Next BORELLI of Naples and AITKEN of Rome looked on it as a peculiar form of malarial fever, whilst DURAND-FARDEL of China and MOREL of French Guiana considered it to be only a severe form of malaria. In 1879 Surgeon-Major H. R. L. VEALE of the Army Medical Department named the disease "febris complicata" and held that it was a definite affection—one that is certainly not typhoid fever and as certainly not a malarial fever, or any modification of typhoid fever by malaria, or engrafting of the taint of malaria on typhoid fever, for the affection is one not yielding to quinine in the slightest degree: the access is insidious and its duration is extremely protracted (being of months rather than weeks and having been known to reach a period of two years); it is characterised now by deceptive convalescences and now by exacerbations, by profuse perspirations which give no relief, and by an extraordinary range of complications affecting all the systems of the body, especially the locomotor apparatus. The importance of this disease to England is evident from the fact that Malta is not only a winter resort and an important commercial centre but is also a naval station for a large fleet and a half-way house in which regiments are acclimatised before proceeding to India. It contains a permanent force of over 25,000 soldiers and sailors and may at any time become the seat of warlike operations, when every available man is of vital importance. All these troops must be exposed to this endemic fever and its lengthened duration causes an enormous yearly financial loss from non-effective pay and invaliding, whilst it may be said to be the most important and, next to venereal diseases, the most prevalent form of sickness affecting our Mediterranean forces. In other parts of the world the disease has been shown to exist and as affecting the British army we may note its appearance in India. The first step in the true elucidation of the disease was the discovery in 1887 of the specific micrococcus Melitensis by Colonel DAVID BRUCE, C.B., R.A.M.C., and now, 20 years later, the concluding report (No. VII.) has been issued of the Commission which was appointed under the auspices of the Royal Society and which began its investigations at the commencement of June, 1904. These investigations have been crowned with success, for at length the facts regarding the causation of the disease have been demonstrated and the Commissioners have determined the paths by which the specific micrococci find their way out of the bodies of infected men or of infected animals. Examination of the breath, saliva, sweat, and scrapings from the skin yielded negative results, the discharges from the bowel are still in the doubtful category, while it was shown that the main paths are by milk and by the urine, and of these the first is the most important. In Malta a very large percentage of the goats are infected and their milk contains the specific micro-organism. The chain of arguments presented in the report is conclusive as to the part played by the Maltese goats in propagating the disease and this is strikingly confirmed by what has happened in Gibraltar. While Gibraltar Rock obtained its milk from goats supplied from Malta it was as liable to the fever as that island, but of recent years Maltese goats have not been allowed to enter Gibraltar and the fever is now non-existent in that station.

The Commission concludes its report with a series of valuable suggestions, and these, of course, will be put in force as regards our own garrison, but there is no such certainty with regard to the action of the native Maltese. It is to be feared that nothing will be done to purify their herds of this disease unless the utmost publicity is given to the fact that the ingestion of infected goat's milk, if not the only cause, is at any rate the main cause of the infection. We trust, therefore, that the native inhabitants of Malta will see the wisdom of setting their house in order in accordance with the facts led up to by the unremitting work of many competent observers and now established by the valuable researches of the Commission sent out under the auspices of the Royal Society.

WEST LONDON POST-GRADUATE COLLEGE.—The annual dinner of the Post-Graduate College and of the past and present members of the West London Hospital will be held at the Trocadéro Restaurant, Piccadilly-circus, on Wednesday, June 12th, at 7.30 P.M., Mr. *Lloyd Williams* in the chair. Any gentlemen who have worked at the Post-graduate College of the hospital will be welcome and tickets (7*s.* each) can be obtained on application to the honorary secretary of the dinner, Mr. L. A. Bidwell, 15, Upper Wimpole-street, W.

the group for the years 1860-92 the sequence of percentages for the fathers of the six classes of sons was 36·2, 32·2, 29·4, 24·7, 13·8, and 12·8. Similarly in the group for the years 1830-60, it was found that of the fathers of the first-class honour men 41·0 per cent. obtained either first- or second-class honours themselves, while of the fathers of the second-class honour men only 40·7 per cent. obtained either first- or second-class honours themselves; in this group the complete sequence of percentages for the fathers of the six classes of sons was 41·0, 40·7, 33·3, 28·1, 20·1, and 12·9. The Oxford records also enable the average resemblance between brother and brother, as well as between father and son, to be estimated numerically. The mean value obtained for the fraction expressing the degree of resemblance between father and son is 0·312, and that between brother and brother is 0·405. Before proceeding to discuss the results deduced from the data supplied by Harrow and Charterhouse schools—a discussion which considerations of space prevent us from touching upon—Mr. Schuster and Miss Elderton express the opinion that their investigations support the view that the physical and psychical characters in man are inherited with nearly the same intensity.

THE COST OF FLAVOUR.

PHYSIOLOGICAL chemists occasionally delight to tell us that we are the dupes of æsthetic senses and pleasing flavours. Men will pay, they say, half a guinea for a pint of turtle soup which, from a strictly nutritive point of view, is not worth a twentieth part of that sum. Oysters, we are told, are an extravagant form of food, since 14 of them do not contain as much nourishment as a single egg, while it would require the ingestion of no less than 200 good oysters before the protein equivalent of a pound of beef was reached. Caviare, again, is not to be compared with the bloater as regards its nutritive value; indeed, the latter "offers the largest amount of nutriment for a given sum of any animal food." It is evident if we regard these conclusions seriously that a large section of the human race is wickedly indulgent, caring more for the palatable than the nutritious quality of food. The same appears to be true in regard to beverages, and even in the case of cigars there is no difference, chemically speaking, between the penny Pickwick and the shilling Havana. The difference of 11*d.* is paid for flavour, and flavour alone. Physiologically, it is possible that a "brandy-and-soda" costing say 1*s.* is just as satisfactory as a "pint" of champagne at 5*s.* Similarly it may be said that a pint of beer at 6*d.* is quite as good, dietetically speaking, as a small bottle of Château Margeaux at 3*s.* 6*d.* There are, however, clearly instances in which in no sense can the nutritive equivalent of food and beverages be summed up in so many pounds, shillings, and pence. How often is it found, for example, that the invalid may be tempted to take a few oysters in preference to a small beef fillet, or some turtle soup when calves' head, the basis of mock turtle, would scarcely appeal to him, even although it may be more than equal in nutritive value to the only reptile used to any extent as food in this country. When a person refuses to take a given food, however nutritive and wholesome it may be, because it is not tempting to the sight or the palate, it is in many instances probable that if he struggles to overcome his fastidiousness such food may prove to tax his digestive functions and may even cause gastric trouble. The chemical analysis of food and physiological experiments in the test tube do not take into account this psychical factor of digestion, for the digestive process is well begun when the sight of food is pleasing. On the contrary, when food does not appeal to the eye it is likely not to appeal to the stomach. It is hardly reasonable to conclude, therefore, that the price of flavour is always the price of luxury. It is wrong, of course, to give way constantly to the promptings of the fanciful palate, and there is little doubt that when this outrage on a healthy function is permitted it is akin to the evil which follows the frequent imbibition of alcoholic drinks. In both cases over-stimulation wears out the normal impulses. The man who enjoys plain food is miles ahead, physically and physiologically speaking, of the man who would leave his meal untouched if it were not that every item of it was calculated "to tickle the palate."

THE INTERNATIONAL CONGRESS OF LARYNGOLOGY AND RHINOLOGY.

THE committee of this Congress, which is to be held in Vienna from April 21st to 25th, 1908, in honour of Türck and Czermak, has decided to organise an exhibition connected with laryngology, rhinology, œsophagoscopy, and bronchoscopy. Among other objects to be shown will be instruments for examination, treatment, and operation, apparatus for inhalation, electro-medical apparatus for lighting and other technical objects, "prostheses," manuscripts, books, preparations, drawings, and the like. The committee invites all those interested to take part in this undertaking. All communications should be sent to the secretary of the Congress not later than Dec. 31st, 1907, Dr. M. Grossmann, Garnisongasse, 10, Vienna, IX. An exact description of the objects to be shown should be sent for the purpose of drawing up a catalogue. All exhibits should be forwarded by, at the latest, Feb. 15th, 1908, to Herr Ober-Ingenieur Jaroschka, Inspektor des k.k. Universitätsgebäudes, Vienna, in whose charge they will be. The executive committee guarantees that all objects sent shall be insured against fire, burglary, and damage, while the Customs authorities have agreed to allow free ingress and egress to exhibits. Any other information in connexion with the exhibition may be obtained from the secretary.

THE MEDICAL DEFENCE UNION.

WE need no excuse for again calling attention to the excellent work of the Medical Defence Union, which attained its majority last year. The report for 1906 which has been recently issued is one that is well worthy of the attention of the profession. There is little doubt that a still further increase in membership would result from a wider appreciation of the benefits accruing therefrom and the serious risks attendant on medical practice without such a safeguard. The council especially desires to bring these facts to the notice of recently qualified men and in this we strongly second it. There is an unfortunate tendency for men holding medical appointments to think that it will be time enough to consider the question of medical defence when they go into practice and that the broad shoulders of their hospital will bear the brunt of any charges that may be brought against them personally. That this is a great mistake is proved by a case quoted in the very interesting report of the Union's solicitor, Mr. W. E. Hempson; a visiting surgeon and house surgeon of a hospital were made co-defendants in a mischievous action for damages brought by a woman who alleged that she had suffered injury through their negligence, whereas it was really entirely through her own negligence of their instructions that she had suffered. Although "the judge made some very strong comments upon the nature of the action, and a verdict was given in favour of both defendants with costs," yet the woman, who was married, had sued in her own name alone, thus rendering her husband secure from claim, and not one penny of the £170 spent in defence was recovered. Many other cases are recorded of equal audacity; in one that seems almost incredible to the non-legal mind a vindictive litigant brought five consecutive actions in as many county courts against a consultant for damages for with the station are 52 "call posts" at different parts of the City, whence any constable can summon the ambulance as soon as an accident occurs; the call goes through to the Old Jewry head police office and is telephoned on to the ambulance. A constable with "first-aid" training accompanies the chauffeur and returns inside the car with the patient. The first accident attended on May 13th was in Queen Victoria-street and the car reached it, returned to St. Bartholomew's Hospital, and was in its garage again within 20 minutes. The service was inaugurated on that day by Sir Alfred Newton, the chairman of the City police committee, in the presence of a representative gathering of City officials and others interested in ambulance work. If this motor ambulance prove a success, as from the efficiency of its instalment there is every reason to hope, it is proposed shortly to add two more cars. The London public should greet with great satisfaction so excellent an attempt to meet a long-felt need.

DEATH OF DR. ROBERT BARNES.

WE much regret to announce the death of Dr. Robert Barnes, which occurred at his residence, Bernersmede, Eastbourne, on Sunday last, May 12th. As Dr. Barnes was only a few months short of 90 years of age his death can hardly be regarded as unexpected, although when it occurred it was sudden. The medical world has lost in him one of the most able and advanced exponents of the science and art of midwifery, and we personally have lost an old and valued friend. For many years Dr. Barnes was a member of our staff and those who have read his published works will not require to be told that his contributions to our columns were alike scholarly, clear, and vigorous. We shall publish an extended memoir in an early issue of THE LANCET.

WOMEN'S NATIONAL HEALTH ASSOCIATION OF IRELAND.

THE rapidly growing interest in the health of the nation has taken form in Ireland under the auspices of Her Excellency the Countess of Aberdeen, wife of the Viceroy, who has already done an incalculable service to the country by establishing the Irish Industries Association, of which she is President. The cause of fostering national industries cannot be more profitably served than by fostering a healthy race of people, and the objects of this new association are well calculated to secure that end. They are officially stated in these words:—

> 1. To arouse public opinion and especially that of the women in Ireland to a sense of responsibility regarding the public health. 2. To spread the knowledge of what may be done in every home, and by every householder, to guard against disease, and to eradicate it when it appears. 3. To promote the up-bringing of a healthy and vigorous race.

The problems proposed for consideration are those which so frequently find a place in our columns, such as tuberculosis, milk-supply, infant mortality, school hygiene, and inspection. Any woman resident in Ireland is invited to become a member and there is no compulsory subscription, although voluntary contributions are very naturally solicited. The methods of work suggested include: popular lectures by medical men and others and conferences on health subjects; simple health talks with small circles of working mothers; the appointment of women health officers, health visitors, and sanitary inspectors; the bringing before local and other authorities any sanitary requirements of the district and the promotion of public opinion in favour of the carrying out of such improvements; the compiling and general distribution of simple health leaflets and other health literature; the teaching of hygiene and of domestic science in every school; the appointment of district nurses in districts where such are not already working and the periodical inspection of school children by district nurses; and the creation of local dispensaries for special purposes where needed. At the inaugural meeting on March 13th a provisional committee was appointed of which the Countess of Aberdeen is President and honorary treasurer, and Mrs. Rushton, 58A, Rathmines-road, Dublin, has been appointed organising secretary. A memorandum has been published giving suggestions for forming local branches of the association and indicating means whereby the aims of the society can be advanced. We trust that the association will meet with success.

THE INHERITANCE OF INTELLECTUAL ABILITY.

ATTEMPTS have at various times been made to analyse the intricate conditions of heredity in mental qualities so as to express the results in some form suitable for tabulation. Mr. H. Havelock Ellis in 1904 published "A Study of British Genius," the data for which he culled from the volumes of the "Dictionary of National Biography." A more convenient source of statistical material has been utilised in a recent memoir[1] by Mr. Edgar Schuster, first Francis Galton Research Fellow in National Eugenics in the University of London, and Miss Ethel M. Elderton, Francis Galton Scholar in National Eugenics in the University of London. In this memoir the writers base their conclusions on the Oxford class lists (examinations for the B.A. degree) and the school lists of Harrow and Charterhouse. The Oxford material was derived from the later volumes of Foster's "Alumni Oxonienses" and its continuation "Oxford Men and their Colleges," and from the "Oxford Historical Register." The object of the research was to "measure the average resemblance between father and son" and may be briefly outlined as follows. It is known in a general sort of way that the sons of those fathers who are more intelligent than the average of fathers are themselves, on the whole, more intelligent than the average of sons. If, therefore, a group of fathers be considered, the intelligence of each of whom is the same definite amount A above the average intelligence of all fathers, the sons of this group will form a group whose average intelligence is a certain definite amount B above the intelligence of all the sons of all the fathers. If the ratio of B to A is unity, B is equal to A, which means that the sons of any particular group of fathers of given intelligence differ in intelligence from the average of all the sons by exactly the same amount as the intelligence of their fathers differed from the average intelligence of all the fathers. When the ratio of B to A is unity the resemblance between father and son is complete and perfect, and every intermediate value between 1 and 0 expresses a different degree of resemblance. The first step in the process of tabulation was to divide the men into three groups according to the years in which they took, or should have taken, their degrees, the limits of the three groups being as follows: 1800–30, 1830–60, and 1860–92. Taking the group 1860–92, and dealing only with those men whose fathers were educated at Oxford, it was found that the group consisted of 2459 persons who were arranged in six divisions, according as they had been placed in the first, second, third, or fourth class in the University lists, or had taken merely a pass degree, or had not taken a degree. Each of these six classes was sorted again according to the degree taken by the father. In this way it was found that of the fathers of the first-class honour men 36·2 per cent. obtained either first- or second-class honours themselves, while of the fathers of the second-class honour men only 32·2 per cent. obtained first- or second-class honours themselves, and of the fathers of the third-class honour men only 29·4 per cent. obtained first- or second-class honours themselves. In common form to print English carelessly and to make a mess of English designations. Many a Frenchman, for instance, writes "Sir Jones" with his eyes open, knowing that he is incorrect, but conniving, as it were, at popular error. But after discounting this tendency we are faced by the unpleasant suspicion that English science and the English language are still regarded as barbarous and negligible by the average Frenchman of scientific culture.

---

EPIDEMIC CEREBRO-SPINAL FEVER.

CASES of epidemic cerebro-spinal fever continue to be reported from many parts of the country. The first occurrence of the disease in the city of Nottingham was announced a few days ago. The patient, who is a boy aged eight years, is said not to have been out of Nottingham for some time and the origin of the infection is unknown. Other cases have presented themselves at Manchester, at Wrexham, and at Pilsley in Derbyshire. In Scotland during the week ended May 11th there were 16 deaths from this cause registered in Glasgow, six in Edinburgh, four in Leith, two in Paisley, and one in Dundee. In Glasgow the weekly report issued on May 10th showed that there were at that time 127 cases under treatment. Cases have also occurred at Perth, at Elgin, at Paisley, at Port Glasgow, and at various villages and small towns in the counties of Dumbarton, Fife, Forfar, and Stirling. In Belfast there has now been a total of 393 cases with 279 deaths.

THE PASTEUR INSTITUTE OF INDIA.

WE have received the sixth annual report of the Director of the Pasteur Institute at Kasauli dealing with its work between August, 1905, and August, 1906. Its scope has increased wonderfully and during this period 1145 persons have been treated and 117 other cases investigated but not treated, as satisfactory evidence was forthcoming to show that the animals which had bitten them were not rabid. The director insists on the importance of securing the biting animal alive in every possible case and of observing it for ten days, which period covers the time during which it may be virulent; if no sign of rabies appears within this limit the person bitten is in no danger and needs no treatment; the examination of the brains of dead animals has only a very limited negative value. The systematic slanderers of experiments on animals, whose predecessors attempted to cast such obloquy on Pasteur during the last century, may be well answered by a single extract from this report. "The increase in the number of patients is undoubtedly due to the wider diffusion of knowledge of the treatment and to appreciation of its results." These results are sufficiently striking; statistics are very variable as to the mortality attendant on bites by rabid animals, but 15 per cent. is almost certainly a low estimate amongst untreated patients. At the Institute of India during the last five years amongst patients there treated who had been bitten by animals definitely proved to have been rabid (either experimentally or by the development of the malady in other animals bitten by them) the mortality was *nil* for 415 Europeans and 0·97 per cent. for 409 Indians. Amongst those bitten by animals certified by a veterinary surgeon or medical officer to have been rabid there were 245 Europeans, of whom none died, and 213 natives, of whom 0·93 per cent. died; and of those bitten by animals only suspected of rabies 0·13 per cent. of 721 Europeans and 1·3 per cent. of 1733 Indians died. This can only be called a triumph of applied experimental science, the more especially as many of the patients treated were bitten by wolves and jackals, animals in which the virulence of the disease is frequently exalted. The compilers of the excellent report from which these figures are quoted insist strongly, however, on the urgent necessity of corporate preventive measures to control the scourge in India, and appeal to private persons to exercise more restraints on animals that have been bitten. It is obvious that much might be done in this way, even though a muzzling order could scarcely be applied to any purpose in a land full of wild animals. The report points out that this institute will this year become the Pasteur Institute of Upper India only as a similar institute is to be established at Conoor. Further extension is needed at Kasauli, however, and an appeal is made to wealthy Indians to provide increased accommodation, especially for the lodging of native patients.

THE TREATMENT OF GONORRHŒA.

THE *Scottish Medical and Surgical Journal* for May contains a useful paper on the treatment of gonorrhœa by irrigation from the pen of Dr. J. S. Purdy who has made some interesting experiments in order to demonstrate that ordinary urethral injections do not penetrate beyond the membranous urethra. With a four-drachm glass syringe he injected into the urethra of a cadaver a solution of methylene blue. He found that staining occurred as far as the termination of the membranous portion but no further. On using the douche tin an elevation of 2½ feet was sufficient to stain the prostatic urethra and of 3 feet for intravesical irrigation. On the living subject an elevation of not less than 5½ feet was necessary to reach the bladder without a catheter. For intravesical irrigation it is better to use a catheter. Although the resistance may be overcome by using a column of water sufficiently high, it is not always advisable to do so, especially in nervous patients. Dr. Purdy has previously published his experience in the treatment of gonorrhœa with the new organic compound of silver, protargol, at the London Lock Hospital.[1] This body has the advantage of being non-irritating even in strong solutions. After first washing out the urethra he injects four times daily a 5 per cent. solution, which the patient holds in the urethra for at least five minutes. In from four to 10 days all obvious discharge ceases. On the cessation of the discharge he uses a weak astringent injection, a solution of sulphate of zinc, one grain to the ounce, which is held in the urethra for half a minute. In some cases cure is completed within 14 days. In posterior urethritis Dr. Purdy has obtained good results from deep instillations of silver nitrate and in some obstinate cases finds this method necessary but he considers that no method gives such uniformly satisfactory results as urethral and intravesical irrigation. He uses a double-channel nozzle made of celluloid or metal, consisting of two tubes concentrically arranged so as to allow the fluid to flow through the inner and to return by the outer. An ordinary burette clip serves to control the stream. Dr. Purdy's experience of the urethroscope is not fortunate. In some cases the disease was even aggravated by its use. Much practice and skilful manipulation are required in order to use this instrument with benefit.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE British Association has now reached the age of 77 years and its comprehensive objects must be well known to our readers; in the words of its constitution they are: "To give a stronger impulse and a more systematic direction to scientific inquiry; to promote the intercourse of those who cultivate science in different parts of the British Empire with one another and with foreign philosophers; to obtain more general attention for alleged injury; in every one of them the verdict was given against the plaintiff with costs, but, as usual, he was a man of straw and none were recovered. The possibility of such exploitation of the law courts for the persecution of medical men is a serious defect of our legislative machinery and one which would press well-nigh intolerably on the profession if it were not for such beneficent aid as is afforded by the Medical Defence Union and similar useful bodies; in one case last year which passed through three trials and two appeals the costs against the Union amounted to nearly £800, five other cases averaged over £100 each, and of the entire 193 cases which passed through the solicitor's hands 20 accounted for £1729 of the total law expenses of the year; it is obvious that few practitioners could bear such burdens unassisted. It is a noteworthy fact that speaks volumes for the increasing respect entertained for the Medical Defence Union as an opponent, that whereas ten years ago its solicitor had to deal with cases representing 6 per cent. of its membership, during last year with a doubled membership he had to treat little more than 3 per cent.; this means that the decisive preliminary action of the general secretary, Dr. A. G. Bateman, was quite sufficient to nip a large number of threatened actions in the bud. The wide field of utility of Dr. Bateman's work in settling internal as well as external professional dissensions and advising on many legal matters is well exemplified in the report by a schedule of cases selected from the minute-book. It is satisfactory to read that the financial condition of the Union is sound and that the membership of 7042 shows an increase of 667 on the previous year. The council expresses a hope that each member may bring in a new one during this year and we are pleased to take this opportunity of giving further publicity to so excellent an aspiration.

---

[1] THE LANCET, Dec. 12th, 1903, p. 1715.

PELVIC ABSCESSES OF APPENDICAL ORIGIN.

Mr. Gilbert Barling recently gave a clinical lecture at the General Hospital, Birmingham, on a somewhat unusual form of pelvic abscess derived from an appendicitis. The lecture appears in the present issue of THE LANCET and to it we refer our readers for a full account of the case. The essential points are these. A man, aged 42 years, had for ten years suffered from recurring attacks of abdominal pain, with vomiting and constipation. A year before admission he had cystitis, which had continued, though less severe, to the date when he was first seen. Nothing was to be felt in the right iliac fossa, but per rectum on the left side of the pelvis was a large dense mass with some fulness on the right side. The cystoscope showed only a diffuse inflammation of the mucous membrane of the bladder; there was no ulceration. When the abdomen was opened in the middle line immediately above the pubes, on the right side was found the appendix surrounded by a few drachms of pus; but on the left side of the pelvis was a large abscess containing several ounces of very fœtid pus. This abscess was completely distinct from that surrounding the appendix. There was no communication between either abscess and the interior of the bladder, so that the cystitis was due to an extension of inflammation from the abscess through the bladder wall and not to any direct communication between them. The chief interest in this case is connected with the abscess on the left side of the pelvis. It is as a rule easy to find an abscess surrounding an inflamed appendix, but unless the surgeon is on the look out for it pelvic abscess due to the appendicitis, but not anatomically connected with it, is very likely to escape notice. The condition is important and hitherto it has not received the recognition which it deserves. Bérard and Patel were apparently the first to distinguish as para-appendicular those abscesses in the pelvis which are unconnected anatomically with the inflamed appendix, though resulting from the appendicular inflammation. In many cases of pelvic abscess there are special symptoms which are referable to the abscess; these are mainly vesical and rectal. Frequent or painful micturition may be present or even retention of urine. The rectal disturbance may manifest itself as tenesmus or diarrhœa may occur. If any other symptoms of appendicitis are present these symptoms should always suggest the presence of a pelvic abscess. If no signs of appendicitis are obvious there is great likelihood of the vesical irritation being looked upon as due to cystitis or a stone may be thought to be present. In Mr. Barling's case the history suggested appendicitis but the symptoms at the time of admission were almost limited to those of cystitis. A rectal examination, however, disclosed the presence of the pelvic abscesses.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN IN DUNFERMLINE.

THE first annual report by Dr. R. V. C. Ash on the Medical Inspection of School Children in Dunfermline under the local Carnegie Trust is before us and is an admirable example of what such a report should be, the information being carefully tabulated and illustrated by lucid charts. It is based on the examination of 2000 school children of all ages, of whom the great majority were boys, and is the result of a scheme which aims at the medical examination of all children in Dunfermline on entering school, on passing into the senior department and on leaving; the last examination is strongly advocated as a help in deciding the child's future career. Where defects are found the requisite treatment is adopted, and especial care has been devoted to defective eyes and teeth, and the presence of adenoids. Curves showing average height, weight, and chest measurements compared with those of the Anthropometric Committee's standard are included. No children were examined without the previous consent of their parents being obtained, and it is interesting that although there was considerable opposition from this source at the inception of the scheme, such trouble is rarely encountered now that there is a more general appreciation of its objects. The parents are informed of any defect that is found and a similar intimation is given to the medical attendant under whose care the case will fall.

FRENCH MEDICAL MEN AND THE ENGLISH LANGUAGE.

THE evidence of bibliography as to the state of national culture is extremely instructive. In the Montpellier theses, of which some 420 were published between the years 1900–04, it has been customary to insert a literature of all the authorities consulted by the individual writers, and this is printed at the end of the thesis and immediately in front of the quaint Hippocratic "*serment*" sworn to at Montpellier by every candidate on attaining the doctorial degree. From these literatures or bibliographies, some of which are voluminous, it may be inferred that young French medical men read little outside the limits of their own language. The great majority of authorities quoted are French, as we should expect in a country where the average man is as proud of his mother tongue as an ancient Roman was of his. It is curious, however, to note that while lengthy German articles, couched in all the complex obscurity of the most original of languages, are often correctly cited, English but seldom makes its appearance in the bibliographies constantly printed in Montpellier. When it does it has mostly undergone torture. Well-known English surnames are rarely rightly printed. A Dr. Macleod appears as "Mocleod," Sir Frederick Treves figures as "Trêves," and so forth. As to the transcripts of titles of books and articles they often baffle us entirely. Of course, some allowance must be made for the fact that in France, even in these days of the *entente*, it is through handling ponies harbouring the specific micrococcus. In none of the cases examined could any evidence be gathered of the spread of the fever by means of mosquitoes or other biting insect, although it is stated that flies may act as carriers. The investigation of the garrison resulted in the following indications: (*a*) that the goat is the primary source from which the disease is spread; (*b*) that goat's milk is the common vehicle for the micrococcus Melitensis; (*c*) that flies may act as carriers; and (*d*) that the other paths of infection play but a minor part. Contact and dust are possible, but probably very infrequent, factors, while the case for mosquitoes and other biting insects is not proved.

The last section of this volume deals with the fever in the civil population. Tables are given showing that it occurs all through the year, with an increase during the hot-weather months. With regard to sex, males and females appear to be about equally liable. The case mortality in the civil population for the ten years from 1896 to 1905 worked out at about 9·5 per cent. as compared with 3·3 for the garrison. Here, again, goats' milk is incriminated as the factor in the causation of the fever, a point well brought out by Dr. A. Critien, of the Public Health Department, Malta.

The volume concludes with a general summary of the facts by Major McCulloch and Major Weir and Staff Surgeon Clayton, and with a series of recommendations, the most important of which have reference to the goats. As a result reacting goats will be segregated and where found to be persistently infected will be killed, compensation being paid to the owners. Condensed milk has been substituted for goats' milk in both naval and military hospitals; the entry of goats into barracks has been prohibited, whilst soldiers, single and married, have been warned as to the dangers of using goats' milk or articles made from it outside their barrack quarters.

The Commission is to be congratulated on the far-reaching results that should be obtained from its labours: the report is one of the most valuable that we have ever perused. For, taking all the facts and arguments into consideration as set forth in the report, it would appear that the Commission has been successful in discovering the main source of infection of Mediterranean fever. This source is the Maltese goats, some 20,000 in number, half of which have been found to be affected by Mediterranean fever, and one-tenth of which are constantly passing the parasite of this disease in their milk. If this source of infection is removed, in all probability the fever will completely disappear from Malta.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN Extraordinary Comitia of the Royal College of Physicians of London was held on May 9th, Sir R. DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair.

The PRESIDENT announced that he had conveyed the congratulations of the College on the occasion of the eightieth anniversary of his birthday to Lord Lister who had returned his warm and sincere thanks for the honour done to him.

The following gentlemen elected to the Fellowship of the College at the last meeting were admitted:—James Barry Ball, M.D. Lond., Arthur Thomas Wilkinson, M.D. Lond., Edward Mansfield Brockbank, M.D. Vict., William James Fenton, M.D. Cantab., Edwin Bramwell, M.B. Edin., Andrew Duncan, M.D. Lond., Robert Jones, M.D. Lond., and Herbert Stanley French, M.D. Oxon.

A communication was received from the Executive Committee of the International Memorial to Semmelweiss, thanking the College for its assistance and sending a medallion struck in commemoration. It was directed that a reply should be sent congratulating the International Committee on the completion of its labours and thanking it for the medallion.

The PRESIDENT announced that he had nominated Dr. M. C. Grabham of Madeira to represent the College at the centenary commemoration of the foundation of the Geological Society of London.

The resignation of Dr. H. Charlton Bastian of the office of curator of the museum was accepted and the thanks of the College were accorded to him for having held the office so long. The PRESIDENT nominated Dr. William Hunter to the post.

A petition was received from the London School of Medicine for Women praying for the admission of women to the examinations of the College. On the motion of the SENIOR CENSOR, seconded by Sir THOMAS BARLOW, it was directed that printed copies of the petition should be circulated among the Fellows before any subsequent meeting of the College at which the matter should be further considered.

After some formal business the PRESIDENT dissolved the Comitia.

NATIONAL ASSOCIATION FOR THE ESTABLISHMENT AND MAINTENANCE OF SANATORIA FOR WORKERS SUFFERING FROM TUBERCULOSIS: THE BENENDEN SANATORIUM.

DINNER IN AID OF THE FUNDS.

His Royal Highness the PRINCE OF WALES presided at a dinner in aid of the funds of the National Association for the Establishment and Maintenance of Sanatoria for Workers Suffering from Tuberculosis held at the Hotel Cecil on Tuesday, May 14th, as a result of which the treasurer, Mr. A. WILLIAM WEST, was enabled to announce a subscription list of £13,261.

The toast of "The King" having been given by His Royal Highness the PRINCE OF WALES, the health of "The Queen, the Prince and Princess of Wales, and the other Members of the Royal Family," was proposed by his Excellency the American Ambassador, and responded to by H.R.H. the PRINCE OF WALES, after which His Royal Highness proposed the toast of the evening, "Success to the National Association for the Establishment and Maintenance of Sanatoria for Workers Suffering from Tuberculosis." He recapitulated the history of the movement and its growth under the patronage of H.R.H. Princess Christian of Schleswig-Holstein. As a result a sanatorium of 200 beds was to be started, in the hope that if it was a financial as well as an educational success it would serve as an inducement to found branches and to encourage the friendly societies to obtain legal powers to draw on their funds to enable them to build similar institutions. As a result of an appeal to public generosity the sanatorium at Benenden, of which the foundation stone was laid on July 14th, 1906, had been built and opened for the reception of patients on March 4th, 1907. His Royal Highness referred to the educational value of such institutions and to the fact that they would relieve existing charities. He pointed out that there were at present less than 1000 beds for the open-air treatment of the working classes in this country and that the yearly victims in London alone were upwards of 16,000 persons, and, further, that it was estimated that in London alone £4,000,000 were annually lost in wages to the working classes by consumption.

Mr. C. H. GARLAND, the chairman of the council, in responding to the toast, referred to the value of the support and patronage of the Royal Family and outlined the scope and objects of the scheme. The association had been able to prove that it is cheaper for the friendly societies to treat and to cure their consumptives than to pay out their sick pay and the final funeral expenses. Their object was to erect an institution which would be no further charge on the charitable public but which would be assured of permanent maintenance from the friendly societies.

Mr. W. G. BUNN also responded and referred to the objects of the association.

DESCRIPTION OF THE SANATORIUM.

The National Sanatorium, Benenden, was formally opened by Princess Christian on April 30th.

The site selected for the sanatorium is on rising ground seven miles from Headcorn and six miles from Cranbrook stations near Benenden, Kent. There is a light railway running to within three and a half miles of the institution. The soil is Lower Greensand, perhaps not absolutely the most ideal soil if money were of no account in the matter, but it was considered that a cheap site was a great essential to the success of the scheme. The situation chosen had also the advantage that two farms adjacent to the site could be the objects of science and the removal of any disadvantages of a public kind which impede its progress." Of the success with which these objects have been attained in the past there is no need now to speak; but we take the present opportunity of calling attention to the forthcoming annual meeting of the Association which will commence at Leicester on Wednesday, July 31st, under the presidency of Sir David Gill, K.C.B., F.R.S., formerly His Majesty's astronomer at the Cape of Good Hope. The sectional meetings for the reading and discussion of reports and papers will be held under the presidency of the following gentlemen respectively: (*a*) Mathematical and Physical Science, Professor A. E. H. Love, F.R.S.; (*b*) Chemistry, Professor A Smithells, F.R.S.; (*c*) Geology, Professor J. W. Gregory, F.R.S.; (*d*) Zoology, Mr. W. E. Hoyle; (*e*) Geography, Mr. George G. Chisholm, F.R.G.S.; (*f*) Economic Science and Statistics, Professor W. J. Ashley; (*g*) Engineering, Professor Silvanus P. Thompson, F.R.S.; (*h*) Anthropology, Mr. D. G. Hogarth; (*i*) Physiology, Professor A. D. Waller, F.R.S.; (*k*) Botany, Professor J. B. Farmer, F.R.S.; and (*l*) Educational Science, Sir Philip Magnus, M.P. The programme of evening meetings includes a reception to be given by the Mayor of Leicester on August 1st in the Abbey Park and a soirée in the museum buildings on the 6th. Excursions to the many "places of interest in the district" will be arranged for Saturday, August 3rd, and the central position of this year's meeting-place is well shown by the fact that such distant spots as Haddon, Warwick, and Peterborough are included under this heading in the prospectus of the association. Tickets for the meeting may be obtained from June 1st to July 23rd at the office of the Association in Burlington House, London, W., and after July 24th at the Reception Rooms at Leicester. Their price to annual members and associates for the meeting is £1; the former receive the reports of the meeting free, and the latter at two-thirds of the published price. Ladies are admitted on equal terms.

A DISCUSSION will take place on Infantile Mortality on Friday, May 31st, in the Western Law Courts, Guildhall, Plymouth, at 7.30 P.M. The chair will be taken by Colonel J. Lane Notter, R.A.M.C., chairman of the council of the Royal Sanitary Institute, by whom the debate has been arranged. The discussion will be opened by Major R. J. Blackham, R.A.M.C., and a general conference is invited. On Saturday, June 1st, visits will be made to the Royal Dockyard and the Plymouth Coöperative Society's bakery.

THE Department of Public Health of Queensland in a bulletin dated April 6th states that for the week ending on that day no cases of plague had occurred. The date of the last case notified was March 17th. As regards Hong-Kong a telegram from the Acting-Governor (received at the Colonial Office on May 13th) states that for the week ending May 11th there were 15 cases of plague and 10 deaths from the disease.

Principal Donald MacAlister, M.D. Cantab., LL.D., D.C.L., will preside at a dinner of the Glasgow University Club, London, to be given in the Trocadéro Restaurant, Piccadilly, W., on Friday, May 31st, at 7.15 for 7.30 P.M. Application for tickets should be made to the honorary secretary, 63, Harley-street, W. It is anticipated that the Right Hon. Lord Kelvin, O.M., K.C.V.O., president of the club, will be present.

THE next session of the General Medical Council will begin on Tuesday, May 28th, at 2 o'clock P.M.; the President, Dr. Donald MacAlister, will occupy the chair.

MEDITERRANEAN OR MALTA FEVER.[1]

THE final reports of the Commission appointed by the Admiralty, War Office, and Civil Government of Malta for the Investigation of Mediterranean Fever are now published and it is sincerely to be hoped that the authorities concerned will read, mark, learn, and inwardly digest them.

In Part VI. we find the record of an immense amount of work by Dr. J. W. H. Eyre, Major J. G. McNaught, R.A.M.C., Captain J. C. Kennedy, R.A.M.C., and Dr. T. Zammit, professor of chemistry, University of Malta. The report opens with a brief summary of the technique employed for the isolation and identification of the micrococcus Melitensis. Then the question of the goat as a factor in the dissemination of the fever is proceeded with and the facts ascertained are noted under the following heads:—1. The Distribution of Milch Goats Naturally Infected with Micrococcus Melitensis. Here the results showed conclusively the necessity for repeated examinations at short intervals of every herd if the detection of *all* the infected animals is aimed at. 2. The Agglutination Test as Applied to the Milch Goat. 3. The Numerical Relationship of Micrococcus Melitensis to the Milk of Infected Goats. 4. The Presence of Micrococcus Melitensis in Milk Products. It could be isolated from cheese and from ice-creams where no heating had been employed in their preparation in order to insure the thorough incorporation of the ingredients; where heating had been used the living organism could not be recovered, although it was known to be present in abundance in the infected milk. 5. The Susceptibility of the Goat to, and Paths of Infection by, Micrococcus Melitensis. Contact infection, subcutaneous infection, and cutaneous infection were all considered and were found capable of communicating the disease, whereas transmission by blood-sucking flies other than by mechanical conveyance upon body or limbs was seen to be extremely improbable.

In the infected goat the micrococcus was next found to be localised in the blood, the spleen, the lymphatic glands, the kidneys, and the mammary gland. A very interesting point was discovered—namely, that while an appreciable amount of specific agglutination is usually transferred from the infected milch goat to the offspring, yet that the micrococcus Melitensis, minute though it be, does not appear to cross the placenta. Experiments are detailed as the result of the administration by the mouth of infected goat's milk to monkeys and it was found that this was followed by an attack of micrococcus Melitensis septicæmia in 83 per cent.

There are many other valuable observations contained in this report; we can, however, only allude to the prophylactic inoculations with micrococcus Melitensis vaccine. The results of this measure certainly encourage the hope that its employment might be a measure of practical utility. The inoculated man enjoyed an immunity for a considerable time from any attack of Malta fever.

In Part VII., which concludes the account of the valuable work performed by the Commission, we find details of the epidemiology of Mediterranean fever in the navy, the preventive measures instituted against this fever in the navy, personal observations as to its prevalence in separate battleships, cruisers, and destroyers during 1906, and facts elicited by the study of individual cases, together with a very complete history of the outbreak of the fever on board the s.s. *Joshua Nicholson*. The facts elicited in this section are ably drawn up by Staff Surgeon F. H. A. Clayton, R.N.

Major T. C. McCulloch, R.A.M.C., and Major J. C. Weir, R.A.M.C., next deal with the disease as it affected the army. They consider amongst other matters the prevalence of the fever in the different branches of the service, comparing its seizure of the artillery and infantry and drawing attention to its special prevalence amongst the Royal Army Medical Corps. The age and amount of service in Malta in relation to Mediterranean fever in Malta are dealt with. Proceeding more into detail, the authors tell us of the result of investigations into the milk-supply, the examination of goats, and the distribution of the cases. The cases occurring in the 1st Battalion Royal West Kent Regiment, in the Royal Army Medical Corps, and in hospital are analysed and instances are narrated in which the men were probably infected bour were other things which he would have to supervise. pidemics and endemics would also be dealt with by him. le (the lecturer) was sorry to say that in Scotland there ere places where typhus fever was endemic because the uthorities were too poor to do anything. Maps of isease would have to be prepared similar to meteorological eports, so that the Minister of Health would be ble to follow, and the public read in the papers, he progress or otherwise that disease was making. A Minister of Health, too, who had the power of ordering a ordon to be placed around areas of sporadic diseases would be in a position to collect valuable information in regard to such diseases. Under the heading of preventive medicine the first place should be given to education and children should be taught to know what things produced health and what things produced ill health. The specific treatment of disease opened up the question of the individuality of the subject, and in regard to vaccination he thought that if it was a good thing for the public health it ought to be enforced. It was ridiculous to have an Act on the statute book if it was not enforced. The new Minister would take over all the powers conferred under the Local Government Board Acts in relation to public health and would have to be assisted by a large and properly coördinated staff. The Minister of Public Health should have the same power with regard to human beings as the *Board of Agriculture* with regard to the lower animals. He should be in the Cabinet and directly responsible to Parliament. He thought that people were realising more and more the importance of preventing disease. If the health of the people was to be effectively dealt with from infant life to adult life the public safety must be put in the hands of experts under the jurisdiction and control of Parliament.

---

[1] Report of the Commission appointed by the Admiralty, War Office, and the Civil Government of Malta for the Investigation of Mediterranean Fever, under the supervision of an Advisory Committee of the Royal Society. Part VI. Pp. 137. Price 3s. Part 7. Pp. 251. Price 5s. London: Harrison and Sons. April, 1907.

In the discussion which followed Sir WILLIAM COLLINS said that in perusing Hansard's Parliamentary Reports it seemed to him that the health of nations occupied almost as much space as the wealth of nations. Accepting central and local organisations as they are, it remained to be seen what could be done to unify the work of each. He would, however, view unfavourably any attempt at over-concentration or at violent coercive legislation—he did not think that a policeman should ever enforce a prescription. Although by his very training a medical man was fitted to take part in public affairs, yet he preferred to regard him as a friend, philosopher, and guide rather than as a benevolent despot armed with an Order in Council. The public must beware lest whilst they were true to humanity they were false to liberty. He confessed on the whole matter he was not prepared to commit himself and thus he had, he hoped, been able to preside with due impartiality.

A resolution was adopted in the following words:—

> That this meeting is of the opinion that the time has come when a Minister of Public Health should be recognised and be given a seat in the Cabinet of His Majesty's Government. In this way not only would the administration of medical matters in the different official departments be systematised but also a much-needed quickening of the "National Health Conscience" would be effected.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on May 9th, Mr. HENRY MORRIS, the President, being in the chair.

Dr. Alexander Hill and Professor Arthur Thomson were introduced and after signing the by-laws and making the required declaration were admitted Fellows of the College.

Mr. Donald J. Armour was introduced and the President handed to him the Jacksonian prize together with a document declaratory of the award.

In accordance with a report from the Court of Examiners it was resolved that diplomas of Membership should be issued to 110 successful candidates.

A report from the Committee of Management on the subject of the teaching of midwifery was approved and adopted. The main points in the report were: (1) that every student shall himself conduct 20 labours, but before conducting these labours he shall be required to have held the posts of medical clinical clerk and of surgical dresser during six months each, and to have attended a course of practical instruction in midwifery; and (2) that every student shall be required to discharge the duties of clinical clerk in the gynæcological wards or out-patient department.

The Committee of Management further reported that it had received from Dr. Theodore Dyke Acland a report on the examinations of the Egyptian Medical School. The thanks of the Council were given to Dr. Acland for his valuable services in the matter.

It was decided that no Fellows' dinner should be held this year.

A letter was read from Lord Lister thanking the Council for its kind words of congratulation on the eightieth anniversary of his birth.

The PRESIDENT stated that, as requested by the Council on Nov. 8th, 1906, he had appeared before the Royal Commission on Vivisection and had given evidence on behalf of the College.

A letter was read from Dr. Thomas James Walker, of 33, Westgate, Peterborough, stating that to mark the completion of the fiftieth year of his Membership of the College he asked the President and Council to accept a volume of original notes of John Hunter's Lectures, taken by Mr. Hopkinson who, 100 years ago, was carrying on the practice now conducted by Dr. Walker in association with his son and Dr. G. Kirkwood. The Council accepted the gift and passed the following resolution:—

> The Council hereby express to Dr. Walker their warm thanks for marking the completion of his fiftieth year of Membership of the College in so generous a manner, and assure him that his very valuable gift will be preserved with the greatest care and appreciation.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On an Outbreak of Enteric Fever in the Borough of Mansfield, by Dr. THEODORE THOMSON.[1]—In this report Dr. Theodore Thomson gives an interesting account of an epidemiological inquiry into an outbreak of enteric fever which occurred last autumn in the borough of Mansfield (in the county of Nottingham) and in the adjacent urban district of Mansfield-Woodhouse. The borough has a population of some 29,000 persons and Mansfield-Woodhouse of about 7000. Typhoid fever had not shown excessive prevalence in either district during previous years. In 1906 a few scattered cases of enteric fever occurred in the borough during the earlier months and seven cases between the beginning of July and the end of September. These were followed by a total of 89 cases in the last three months of the year. The most definite epidemic period was between Oct. 17th and Nov. 11th, during which 60 cases were notified. In Mansfield-Woodhouse the circumstances were parallel, and it was clear that this district had been affected, in proportion to its population, in much the same way as the adjoining borough. In the earlier stages of the outbreak in October suspicion fell on a particular milk-supply. On the premises of the dairyman in question it was the custom to store milk in a back yard. Here there was a pail closet which had been used by an inmate of the dairyman's house who had suffered during September from an illness suspected to have been enteric fever. At first sight the fact that there was no exceptional incidence of enteric fever either in the neighbourhood of the dairyman's premises, among customers buying milk over the counter, or among the regular customers whom he supplied by cart, seemed to remove all suspicion from his milk. But the particular milk which was stored in the back yard and so became exposed to contamination carried from the pail closet by flies or other agencies of transmission of infection turned out to be residual milk which the dairyman habitually sold to other milk dealers in Mansfield whose supplies had run short during the dry weather which prevailed during the summer and autumn of 1906. Several dealers furnishing milk to customers in different parts of the town obtained a supplementary supply in this way, and it seemed that a theory of milk causation might in the circumstances square with the fact that the cases of fever were not localised but were scattered throughout Mansfield and Mansfield-Woodhouse. When the facts came to be worked out fully, however, it appeared that there was no materially greater incidence of enteric fever among customers of milk procured. These farms covered 250 acres and were suitably arranged for the prosecution of the farm colony which is part of the scheme proposed by the association. In regard to water an ample and excellent supply has been obtained from an artesian well 160 feet deep, supplying 2000 gallons an hour, which is raised by a three and a half horse power oil engine to a reservoir on the highest part of the site from which the water will gravitate to the sanatorium.

The National Sanatorium, Benenden, Kent

The institution is divided into a central block to accommodate 68 patients, an administration block and dining hall, and a laundry and electric-light block. Pavilions will be added later bringing up the number of beds to 200. The central portion for 68 patients has been erected 230 feet above sea level, with an uninterrupted view to the south; it is two storeys in height and is divided into two parts by a recreation room which forms the centre of the block; the wings at the outer extremities of this portion of the building are inclined inwards so as to afford shelter. In this main block it is intended to place the more serious cases which are likely to require most medical and nursing attention. Of the rooms provided in this part 20 are single-bedded rooms, the remainder being double-bedded. The fall of the ground has been utilised for placing the sterilising apparatus and the steam boiler under one end of the building. The water for the lavatories and baths is heated by steam as are the rooms by anthracite stoves. The drainage is carried out on the septic tank system. The lavatory towers are cut off from the main building by cross-ventilated corridors. Along the whole length of this part of the sanatorium there is a terrace.

A portion only of the administration block has as yet been erected, consisting of the dining hall and accommodation for the resident medical officer, the matron, the nurses, and the servants. The method of construction is entirely new for this class of building; it is of steel framing throughout, the intermediate space between the stanchions and girders being filled in with "frazzi," cement rough-cast on the outside and plastered on the inside, the floors and partitions being made in the same way. This method of construction offers great advantages. It is certainly economical, for the cost per bed works out at £100. The building is permanent and fireproof throughout; it is warm in winter and cool in summer. Although the floors and doors are of teak it is believed that the extra initial cost will be found to be an economy in the end. Each room has a double French casement opening to the ground directly to the south, and there are open sashes into the corridor at the back at the level of the ceiling. The main objects have been to arrive at a plan which will give the minimum amount of work in its future maintenance whilst at the same time sacrificing nothing in regard to efficiency.

The illustration of the institution is from a photograph supplied by the architect, Mr. A. William West.

"THE NECESSITY FOR A MINISTER OF PUBLIC HEALTH."

Under the auspices of the New Reform Club Dr. A. Rolland Rainy, M.P., delivered on May 10th at Adelphi Terrace an address on "The Necessity for a Minister of Public Health." Sir William J. Collins, M.P., who presided, said that no one who studied the development of legislation or municipal administration could fail to be struck with the fact that the State was tending more and more to seek if not to act upon medical advice. Medical men had already been municipalised and there was a tendency towards nationalising them. He and his colleagues could not help feeling, however, that greater demands were made upon the medical profession by public bodies than medical science and art could respond to, for medicine was not an exact science and did not lend itself readily to the methods and processes of legislation.

Dr. Rainy said that the creation of a Minister of Public Health would put the medical profession on the same basis as the navy, the army, and the legal profession. The navy and army were supported by the State in order that the people might be protected from foreign enemies. In the same way the medical profession would protect us from the enemy, disease. But if the medical profession were lifted into a recognised department of the State it must accept the limitations which a service of this kind imposed. He admitted that he could not quote the conditions prevailing in other countries as a guide but said that his investigations had shown him that the whole matter of public health in this country was chaotic, ineffective, and expensive. With regard to the further question whether, if there were a Minister of Health he should be a medical man he thought that unless there should be a medical man in the House of Commons of very exceptional ability the Minister had better be a layman. The medical profession was represented in the House by a small body, and he could not help feeling that other Members looked upon them very often as seeking the interests of the profession to which they belonged more than that of the public, though, of course, there was no justification for that feeling. It was, however, an important fact to remember, and he considered that it would be unwise to suggest that the new Minister should be a member of the medical profession. The speaker went on to point out the range of the duties of a Minister of Public Health. He would be expected to take charge of the air and to see that air was supplied to everybody under proper conditions. Light would also be under his charge as well as the conditions under which food could be bought and sold and the source of its supply. Clothing was another matter of which he would have some control. With regard to the matter of food and clothing if the people had advanced along Socialistic lines to the extent of saying that a child was to be educated that child ought to be in a position to be taught properly and that implied proper clothing and food. Sanitation and hours of to 21·8 in Leith and 24·0 in Perth. The 671 deaths in the eight towns showed a decline of 19 from the number in the previous week, and included 110 which were referred to the principal epidemic diseases, against 133, 121, and 106 in the three preceding weeks. These 110 deaths were equal to an annual rate of 3·2 per 1000, which was double the rate from the principal epidemic diseases in the 76 English towns; they included 40 from whooping-cough, 36 from "fever," 15 from diarrhœa, 12 from measles, four from diphtheria, and three from scarlet fever, but not any from small-pox. The fatal cases of whooping-cough, which had declined from 55 to 44 in the four preceding weeks, further fell to 40 last week, and included 27 in Glasgow, six in Aberdeen, four in Edinburgh, and three in Dundee. The 36 deaths referred to "fever" showed a decline of ten from the number in the previous week, and included 22 in Glasgow, six in Edinburgh, five in Leith, two in Paisley, and one in Dundee; with the exception of four cases in Glasgow and one in Leith these deaths were attributed to cerebro-spinal meningitis. The fatal cases of diarrhœa, which had been 17, 12, and six in the three preceding weeks, rose again last week to 15, of which eight occurred in Glasgow, three in Dundee, two in Edinburgh, and two in Aberdeen. The 12 deaths from measles were six in excess of the number in the preceding week and included seven in Glasgow, three in Leith, and two in Edinburgh. Two fatal cases of scarlet fever and two of diphtheria occurred in Glasgow, and two of diphtheria in Aberdeen. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 103, 109, and 127 in the three preceding weeks, declined again to 107 last week and were slightly below the number in the corresponding week of last year. The causes of 26, or 3·9 per cent., of the deaths registered in the eight towns last week were not certified or not stated; in the 76 English towns the proportion of uncertified deaths in the week under notice did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 33·5 and 26·4 per 1000 in the two preceding weeks, further declined to 24·0 in the week ending May 11th. During the first six weeks of the current quarter the death-rate has averaged 27·7 per 1000; the rates during the same period being only 18·1 in London and 18·1 in Edinburgh. The 180 deaths of Dublin residents during the week under notice showed a decline of 18 from the number in the preceding week, and included 17 which were referred to the principal epidemic diseases, against 29 and 14, in the two preceding weeks; of these, eight resulted from whooping-cough, six from measles, and one each from diphtheria, from "fever," and from diarrhœa, but not any from small-pox or scarlet fever. These 17 deaths were equal to an annual rate of 2·3 per 1000, the rates during the same period from the principal epidemic diseases being 1·5 in London and 2·3 in Edinburgh. The fatal cases of whooping-cough, which had been 15 and 10 in the two preceding weeks, further declined last week to eight; the deaths from measles showed a marked increase over the number in the preceding week. The 180 deaths from all causes included 37 of children under one year of age and 50 of persons aged upwards of 60 years; each of these numbers showed a slight increase. Four inquest cases and four deaths from violence were registered; and 64, or 35·6 per cent., of the deaths occurred in public institutions The causes of seven, or 3·9 per cent., of the deaths in Dublin were not certified; in Edinburgh the percentage of uncertified deaths was 7·8, while in London all the causes of death were duly certified. The 174 deaths registered in Belfast during the week included 16 which were referred to cerebro-spinal fever or cerebro-spinal meningitis, showing a decline of nine from the number in the preceding week.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeon: F. G. Wilson to the *Hussar*, on completing.

ROYAL ARMY MEDICAL CORPS.

Lieutenant Colonel S. F. Freyer, Lieutenant-Colonel A. S. Rose, Major E. W. Slayter, Captain F. E. C. Robinson, Captain N. E. Harding, and Captain J. B. Weldon have arrived home from India. Captain B. B. Burke has joined at Woolwich. Major G. F. Alexander has been appointed to the medical charge of the troops of the 3rd Infantry Brigade at Aldershot.

IMPERIAL YEOMANRY.

Berks: Maurice Were Coleman to be Surgeon-Lieutenant (extra), under the conditions of paragraph 28, Imperial Yeomanry Regulations (dated April 15th, 1907). Sussex: John Robert Steinhaeuser to be Surgeon-Lieutenant (extra), under the conditions of paragraph 28, Imperial Yeomanry Regulations (dated March 27th, 1907).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Cumberland: Samuel Edward Rigg to be Surgeon-Lieutenant (dated April 1st, 1907). 1st Forfarshire: Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel W. Chalmers Cowan resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated April 3rd, 1907); Surgeon-Lieutenant H. C. Coleman to be Surgeon-Captain (dated April 3rd, 1907).

Royal Engineers (Volunteers): 1st (Sheffield) Yorkshire (West Riding): Joseph Mitchell Benson to be Surgeon-Lieutenant (dated March 26th, 1907).

Rifle: 4th Volunteer Battalion the Cameronians (Scottish Rifles): Surgeon-Captain N. Macnair resigns his commission (dated April 6th, 1907). 1st Volunteer Battalion the Hampshire Regiment: Supernumerary Surgeon-Captain H. M. Brownfield is granted the honorary rank of Surgeon-Major (dated March 4th, 1907). 1st Dumbartonshire Volunteer Rifle Corps: James Patterson Wilson to be Surgeon-Lieutenant (dated Feb. 28th, 1907). 6th Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Lieutenant (Honorary Lieutenant in the Army) M. J. Mahoney to be Surgeon-Captain (dated April 10th, 1907). 2nd Volunteer Battalion the Sherwood Foresters (Nottinghamshire and Derbyshire Regiment): William Duncan to be Surgeon-Lieutenant (dated March 26th, 1907).

DEATHS IN THE SERVICES.

Surgeon-Major Lancelot Armstrong, A.M.D., at Weston-super-Mare, on May 11th. He entered the service in 1854 as assistant surgeon, became surgeon in 1864, and retired with the rank of surgeon-major in 1876. He served throughout the Eastern campaign of 1854–55, including the reconnaissance on the Danube under Lord Cardigan. At Balaclava he commenced the ride with the Six Hundred but dismounted when men were falling and attended to the wounded under the fire of the Russian batteries (medal with four clasps and Turkish medal).

VOLUNTEERS AND AMBULANCE INSTRUCTION.

The annual dinner of the staff and members of the Volunteer Ambulance School of Instruction was held on May 10th at the Trocadéro Restaurant. Surgeon Colonel P. B. Giles, V.D., the commandant, occupied the chair. Lord Methuen, in proposing the toast of "The Army Medical Department," said that had Mr. Haldane been present they would have availed themselves of the opportunity of impressing upon him the desirability of the corps being placed upon a proper footing and having a regimental system. Sir A. H. Keogh, in responding, said all that they asked was that they should be made a consolidated body. He believed that Mr. Haldane was in sympathy with them in that desire.

THE ARMY COUNCIL AND STERILISATION OF WATER.

The Army Council proposes to issue new filter water-carts to the home troops in order that they may be familiarised with methods of water sterilisation.

A MILITARY HOME HOSPITALS RESERVE.

The *Broad Arrow* states that with the sanction of H.R.H. the Prince of Wales the Chapter General of the Order of St. John of Jerusalem has been in communication with the War Office as regards the formation of an organised body to be termed "The Military Home Hospitals Reserve," which will be recruited, so far as the medical staff is concerned, from the St. John Ambulance Association and from the St. John Ambulance Brigade, and, as regards other ranks, from the St. John Ambulance Brigade. Certificated pupils of the St. John Ambulance Association who may possess, or acquire, the necessary qualifications, as (a) compounders, (b) clerks, and (c) cooks, who are willing to volunteer, will be enrolled to fill these dealers who supplemented their supply by milk stored on the premises in question, nor was there reason to suspect other milk. The preponderating ages and sex of the persons attacked were not what are usually found in outbreaks due to infected milk; more males were attacked than females and relatively few children.

Having been able definitely to exclude milk, Dr. Thomson made systematic inquiries as to various other likely or unlikely agencies of infection, but with negative results. These inquiries related in turn to the consumption of shell-fish, ice-cream, watercress and other greenstuff eaten raw, aerated waters, and butter, and to the possibility of the epidemic having originated in infection among persons employed in the local coal workings. It appeared also that there was no special relation of the disease to conservancy systems. In the borough of Mansfield the fever occurred in 1·7 per cent. of 4365 houses with water-closets, 1·2 per cent. of 828 houses with midden privies, and 0·6 per cent. of 807 houses with pail closets. In regard to defects in drainage, removal of refuse, and general cleanliness, the houses in which the disease occurred were, as a whole, no worse than others which escaped, while many were entirely free from defective conditions in these respects. There was no localisation of incidence corresponding to the distribution of particular sewerage systems or particular sewers.

All this negative evidence when considered together with the facts as to the incidence and general distribution of the disease throughout Mansfield and Mansfield-Woodhouse and with the circumstance that these two places are supplied in common by a single water service, tended to direct special attention to the possibility or probability of a water infection. But here also at first sight any hypothesis of infection by the water-supply seemed unlikely. The water is derived from a deep well in the Bunter beds of the New Red Sandstone about three miles out of Mansfield. The well is 110 feet deep and protected by a lining of blue bricks, supplemented by cement concrete backing and by cast-iron tubing for a depth of 69 feet. The Bunter beds consist of compact sandstone and are considered to be practically without fissures. There are, however, certain boreholes by the side of the well to which surface water or drainage from the engine room floor might have gained access and so have reached the supply. In this connexion it is noteworthy that after nearly three weeks of almost complete drought there was a moderate rainfall about the end of the second week in September, followed by an unusually heavy fall on Oct. 2nd. The latter rainfall occurred a fortnight before the commencement of the epidemic proper. Nevertheless on local inquiry Dr. Thomson found nothing to suggest that during the period in question there was any opportunity of specific infection which, in consequence of heavy rainfall or otherwise, might have gained access to the supply. For various reasons it seemed possible to put aside the question of infection having taken place in the mains or otherwise in course of the distribution of the water after it had left the pumping-station. Moreover, water from the same well is distributed, not only to Mansfield and Mansfield-Woodhouse but also to other localities with a total population of 7000, among which no case of enteric fever is known to have occurred during the last four months of 1906. The entire freedom of so large a body of persons from the fever during all these months afforded by itself strong presumption against the water-supply having served as the carrier of infection in the areas invaded by the disease. Dr. Thomson points out, however, that the water supplied to this population of 7000 differs in one respect from that supplied to the greater part of Mansfield and Mansfield-Woodhouse. Before distribution it has a period of rest in one or the other of two local reservoirs, and this rest period may be as much as, or more than, three days. In this relation also attention is drawn to the escape from fever of a small area in Mansfield itself which happens to draw its supply from a special reservoir which insures that the water has a longer period of delay before reaching the consumer than that which furnishes the bulk of the supply. Looking at the whole circumstances Dr. Thomson concludes that the evidence neither warrants the absolute exculpation of the water-supply nor affords ground for its definite incrimination. If, in fact, the water-supply was the causative agent it is clear that the infective material borne by it must have been either small in amount or of little virulence. Had it been otherwise the cases of enteric fever would have been counted, not by tens as was actually the case, but by hundreds. On either of these assumptions the escape of areas which got their water only after passage through a reservoir of comparatively large size would be consistent with the causation of the outbreak by water. In the one case the infecting material might have become so disintegrated and dispersed as to lose its power for harm; in the other, the delay in the reservoir might have caused further loss of virulence to the bacilli concerned.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9039 births and 4816 deaths were registered during the week ending May 11th. The annual rate of mortality, which had been equal to 16·8, 16·0, and 15·9 per 1000 in the three preceding weeks, further declined to 15·7 per 1000 during the week under notice. During the first six weeks of the current quarter the death-rate in these towns averaged 16·5 per 1000, the rate during the same period in London being 16·1. The lowest rates in the 76 towns last week were 5·5 in Northampton, 7·6 in East Ham, 7 8 in Smethwick, and 8·1 in Hornsey; in the other towns the rates ranged upwards to 20·7 in Derby, 20·8 in Manchester, 20·9 in Preston, 21·5 in Coventry, 22·4 in Sunderland, and 23·8 in Salford. The 4816 deaths in the 76 towns showed a decrease of 69 from the number returned in the preceding week, and included 493 which were referred to the principal epidemic diseases, against 507, 532, and 530 in the three previous weeks; of these, 186 resulted from measles, 163 from whooping-cough, 50 from scarlet fever, 48 from diphtheria, 29 from diarrhœa, and 17 from "fever" (principally enteric), but not any from small-pox. No death from any of these epidemic diseases was registered last week in Leicester, South Shields, Halifax, Swansea, or in ten other smaller towns; the annual rates from these diseases, however, ranged upwards in the other towns to 4·0 in Birkenhead, 5·4 in Hanley and in Sheffield, 6·1 in Middlesbrough, and 6 6 in Bolton. The fatal cases of measles showed a slight decline from the high numbers in recent weeks; the highest annual death-rates from this disease were 4 0 in Birkenhead, 4·1 in Sheffield, 4·7 in Hanley, and 5·4 in Bolton. The deaths from whooping-cough, which had risen from 155 to 176 in the three preceding weeks, declined again to 163 last week, the mortality being equal to 1·5 per 1000 in Salford, in Oldham, and in Middlesbrough and 2·0 in Stockton-on-Tees. The fatal cases of scarlet fever exceeded the number in any previous week of this year, while on the other hand the deaths from diarrhœa were below the number in any other week for the past 13 months. Diphtheria caused three deaths in Reading, equal to an annual rate of 1·9 per 1000 Of the 17 deaths referred to "fever" two occurred in Barrow-in-Furness, equal to a rate of 1·7 per 1000. One case of small-pox remained under treatment in the Metropolitan Asylums Hospitals at the end of last week. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2628, 2649, and 2672 at the end of the three preceding weeks, had declined again to 2658 at the end of last week; 349 new cases were admitted during the week, against 361, 360, and 346 in the three preceding weeks. The deaths referred to pneumonia and other diseases of the respiratory organs in London, which had continuously declined from 412 to 282 in the five previous weeks, further fell to 262 last week, but were 14 in excess of the average number in the corresponding week of the five years 1902–06. The causes of 46, or 1·0 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London, Bristol, West Ham, Newcastle-on-Tyne, Hull, Leicester, and in 47 other of the 76 towns; the proportion of uncertified deaths, however, showed considerable excess in Liverpool, Blackburn, South Shields, and Burton-on-Trent.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 20·6 and 19 9 per 1000 in the two preceding weeks, further declined to 19 3 per 1000 in the week ending May 4th, but exceeded by 3·6 the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·9 in Aberdeen and 17·5 in Edinburgh

Medicines and medical aid are necessaries for which an infant may contract and render himself liable, but a parent is not liable to pay for such necessaries furnished to an infant child without some proof of a contract on his part, either express or implied, and no such contract will be implied where the infant has been allowed a sufficiently reasonable sum for his expenses. In Cooper *v.* Phillips (4 C. & P. 581) A had several of his children residing in a house distant from his own in the charge of B, a servant. It was held that if an accident happened to one of the children A was liable to pay for his treatment, although he did not know the surgeon who was called in and although the accident might have arisen from the carelessness of the servant. It was held, also, that if B, the servant, becoming ill in consequence of the service, called in C, a surgeon, and after this A sends his own surgeon, and the wife of A knows of C's attendance and expresses no disapprobation A is liable to pay C for this attendance. A servant who hurt her foot in getting over a gate called in a surgeon who was not the regular medical attendant of the family without the knowledge of her master or mistress. It was held that the master was not liable to pay the surgeon's bill. In dealings between medical men and the guardians of an infant it should be remembered that, although the expenses of an extraordinary illness do not form part of the maintenance of an infant, strictly speaking, yet when there has been no extraordinary illness medicine and the medical men's fees must be included in the general allowance for past maintenance and the court will not allow the guardian to claim an extra sum for the same.

A master is not bound to provide medical assistance for his servant, but the obligation (if any) must arise from contract; nor will such a contract be implied simply because the servant is living under the master's roof nor because the illness of the servant has arisen from an accident met with in the master's services. But after July 1st a master or mistress will be liable in case of accident to a servant. A wife has an implied authority to bind her husband for reasonable expenses for medicine and medical attendances incurred during illness. But this implied authority is put an end to if a wife who is not living with her husband as part of his family commits adultery or if she leaves her husband's house of her own accord and without sufficient reason and the fact has become notorious or the husband has given sufficient notice that he will no longer be responsible for any debts which she may incur. If, however, a husband turns his wife out of doors without the means of obtaining necessaries, it is a presumption of law, which cannot be rebutted by evidence, that she was turned out with the authority of her husband to pledge his credit for necessaries, and in such a case medical attendances will be considered one of the most primary necessaries.

THE MILK-SUPPLY OF LONDON: SOME PERSONAL OBSERVATIONS UPON ITS RAILWAY TRANSPORT.

(FROM A CORRESPONDENT.)

IV.[1]

The Result of a Casual Inspection.—The Methods of the New York Milk-supply.—Suggestions for Reform.

MY investigation, as will be seen, in no sense claims to be an exhaustive one. I have simply made notes of a casual inspection. The number of special milk trains running to each terminus *per diem*, the quantity of milk carried to the terminus, and the proportion of milk left at peripheral railway stations and not brought to the terminus are matters that are all in a way germane to the subject, but I have not dealt with them. I am sure that the officials to whom these things are known would readily give the information to your representative; I have confined myself to talking of the conditions under which milk travels from the country to the London market. To a certain extent, however, the bulk of milk that has to be sent must be regarded, for the enormous quantity required produces difficulties of transport and distribution. Directly or indirectly, this is the reason why on any country platform near London at any time of the day, as well as on many London platforms, milk cans, usually unprotected by lock or seal, may be seen standing about. They are waiting till some train, some van, or some cart is at liberty to move them on a stage nearer the London gullet. The question is whether greater rapidity of transport might not be obtained by more orderly methods. At the present time, both in London and in New York, the two cities of the world approximating most closely in population, efforts are being put forth to improve the condition of the milk-supply. I have lived for many years in New York, and, indeed, have left it but a short time, and I had occasion when living there to make myself acquainted with the conditions of its milk-supply.

The inhabitants of New York city consume *per capita* far more milk than do the citizens of London. For whereas it is computed that London's daily consumption of milk *per capita* is about 0·20 pint, that of New York is, according to the authority of Dr. G. M. Whitaker,[1] considerably more than half a pint. Dr. Darlington, the Health Commissioner of New York, in January, 1905, estimated that the city's daily consumption of milk was 1,388,000 quarts, while an editorial article in the *New York Medical Record*, Feb. 16th, places the amount at 1,600,000 quarts daily. If either of these estimates be correct, then the quantity of milk taken into New York daily may exceed that carried into London daily, though London (meaning the county of London) is greatly the more populous area. The milk which is conveyed by rail to New York comes from several states, though the bulk of it is procured from New York State, and travels distances varying from 40 to 400 miles. The cans usually employed for carrying New York milk contain each ten gallons. These cans are carried by the farmers to milk stations situated near railroad stations, from which they are transferred to the trains regularly and promptly. The greater part of the milk sold in New York is distributed and retailed by dealers who own the railroad milk stations. One third or even more of the milk and cream delivered by the railways in New York is contained in bottles, after having been, as a rule, pasteurised at the railway milk stations. Such milk is generally sold to private companies, while the remaining two-thirds are sent to New York in cans to hotels, restaurants, institutions, and to grocery shops. It is worthy of notice that in New York proper there are 7000 grocery shops at which milk is sold.

The railway vans used for carrying milk to New York by the various railways differ from each other only in point of size and in a few matters of detail. They are constructed on a uniform plan. The milk trains are built on the corridor system and resemble the ordinary American "express" carriages, but the word "milk" is painted on each side of a carriage. These vans have no partitions, so that they can be easily kept clean. They are built on the principle of refrigerator vans, with double walls, a trap-door in the roof for taking in ice, and with openings for ventilation in the sides and at the bottom. Many of the milk vans are supplied with pipes, so that steam can be introduced to prevent the milk from freezing in the winter. In the summer the cars are systematically refrigerated. Some of the milk taken into New York by rail is as long as from 15 to 16 hours on the journey, numerous stops having to be made to collect milk *en route*, but it is an exception when this takes place. As a rule special milk trains are run to New York. Sometimes a passenger carriage is attached to a milk train, while occasionally on certain branch railways a milk van is attached to a regular passenger train, or even to a goods train, but when this happens the arrangement is only temporary, the milk van being transferred to a milk train at the nearest junction. Special milk trains running to New York travel at a higher rate of speed than the fastest expresses. Such trains always arrive in New York by night, generally between the hours of 10 and 11 P.M. Some of the milk carried by rail goes to New York proper, but the greater part is unloaded in New Jersey. There are no wharves used for unloading milk for New York. Milk, like many another commodity, is very much dearer in New York than it is in London, the railway charges for carriage being also higher. The New York Interstate Commerce Commission has fixed this rate, which is as follows: on ten gallon cans of milk up to 40 miles, about 1¼*d.* per gallon; between 40 and 100 miles, about 1½*d.* per gallon;

ratings. The members of this reserve will not be expected to proceed on foreign service but the officers will be required to undertake the administration and the other ranks duties in various capacities of the home military hospitals in time of national emergency, thus enabling the officers and men of the Royal Army Medical Corps, who in time of peace are on duty at these establishments, to proceed at once to the field of operations. The following is the departmental committee of the ambulance department for the institution and development of a Military Home Hospitals Reserve: Chairman (*ex officio*): The Most Hon. the Marquis of Breadalbane, K.G., director, Ambulance Department. Vice-chairman (*ex officio*): Lieutenant-Colonel Sir Richard C. Temple, Bart., C.I.E., assistant director, Ambulance Department. Members: Sir John Furley, C.B.; Colonel Sir Herbert C. Perrott, Bart., C.B., chief secretary, Ambulance Department; Mr. Edwin Freshfield, LL.D., Receiver-General of the Order; Colonel Sir Charles Moore Watson, K.C.M.G., C.B.; Sir Dyce Duckworth, LL.D.; Inspector-General Belgrave Ninnis, R.N., Chief Commissioner, St. John Ambulance Brigade; Surgeon-General Sir Alfred H. Keogh, K.C.B., Director-General, A.M.S.; Surgeon-General Sir William Taylor, K.C.B., K.H.P., late Director-General, A.M.S. Honorary secretaries: Colonel Sir Herbert C. Perrott, Bart., C.B., and Surgeon-General Sir William Taylor, K.C.B., K.H.P.

ANTITYPHOID INOCULATION IN THE ARMY.

The *Journal of the Royal Army Medical Corps* for May is a very good number and the three first papers, which deal with antityphoid inoculation in the army, are of such an interesting and important nature as to call for detailed consideration. This, however, we are for the moment unable to accord to the subject and must consequently be content for the present to call special attention to the articles in question. The first is by Brevet-Lieutenant-Colonel W. B. Leishman, R.A.M.C., on the Progress of Antityphoid Inoculation in the Army. This is followed by a Report on the Results of Experiments in Connexion with Antityphoid Vaccination, by Major W. S. Harrison, R.A.M.C., and by a Report on the Outbreak of Enteric Fever and the Effect of Antityphoid Inoculation among the 17th Lancers, Meerut, India, by Lieutenant E. J. H. Luxmoore, R.A.M.C. Colonel Leishman gives a brief but lucid and interesting history of the system of protective inoculation against enteric fever in the army from its introduction by Sir A. E. Wright in 1897 up to the present time, inclusive of the facts connected with the occurrence of a severe epidemic of enteric fever in the 17th Lancers shortly after their arrival at Meerut in 1905 as set forth by the attached medical officer, Lieutenant Luxmoore. The evidence afforded on this occasion as to the protective effect of the inoculations was of a striking and exceptional kind and partook of the nature, and had consequently the value, of a scientific experiment. The history of the subject, the progress of antityphoid inoculation, and the latest observations in regard to it as set forth in the above papers strike us as interesting and instructive, as well as indicative of the hopeful progress that is being made.

"Audi alteram partem."

A DEGREE IN MEDICINE FOR THE AVERAGE LONDON STUDENT.

To the Editors of THE LANCET.

SIRS,—At the recent senatorial elections of the London University the Graduates' Association carried by large majorities four of the five contested vacancies and in the other two instances its candidates were elected unopposed. It must also be remembered that it won both seats which fell vacant in October last. I was not returned last Tuesday but since I came out Sir Thomas Barlow has renounced, for a time at least, the concentration scheme and the union has pledged itself to maintain the standard of the degrees. These were the two main planks of my platform. Our object is therefore attained and I heartily thank the 343 medical members of Convocation who supported me with their votes and influence. With the present Senate there will be no lowering of the standard. How, then, is the average medical student in London to obtain a degree? It seems possible in one of two ways: (1) by reciprocity in the matter of examinations between the London University and the universities of the provinces and colonies, or (2) by the adoption of the one-portal system, carrying with it a degree or the title of Doctor.

I am, Sirs, yours faithfully,

London, May 11th, 1907. ERNEST W. WHITE.

LARGE VESICAL CALCULI.

To the Editors of THE LANCET.

SIRS,—In connexion with Mr. Littlewood's letter I may mention that about eight years ago at the Ancoats Hospital, Manchester, I removed (suprapubically) a calculus weighing nine and a half ounces, flattened ovoid in form, and *encysted* in the trigone to about half its periphery. It was a case presenting great difficulties, but was removed without "seeing" the peritoneum and the man made a perfect and rapid recovery. He was only 22 years of age and had been at active work up to the day on which he presented himself to my out-patient room. Sir Thomas Smith's operation, quoted by Mr. Littlewood, I well remember, as I was present at it; the man was a waiter and he, too, had been working almost up to the time of operation. He, I believe, had had some hæmaturia, my man had not. I have also in my possession a (double) *prostatic* calculus which weighed 552 grains which I also extracted at the same hospital by median perineal section. I believe this to be nearly a record weight for a prostatic calculus. If the Museum of the Royal College of Surgeons of England cares to have these specimens I shall be very pleased to forward them.

I am, Sirs, yours faithfully,

C. E RICHMOND, B.Sc. Vict.; F.R.C.S. Eng., &c.

Stockton Heath, Warrington, May 12th, 1907.

RECOVERY OF MEDICAL FEES.

(FROM A LEGAL CORRESPONDENT.)

EVERY person registered under the Medical Acts is entitled to practise medicine and surgery in any part of His Majesty's dominions and to demand and to recover in any court of law, with full costs of suit, reasonable charges for professional aid, advice, and visits, and the cost of any medicines or other medical or surgical appliances rendered or supplied by him to his patients, but no person is entitled to recover any such charges in any court of law unless he can prove upon the trial that he is so registered. It is not, however, essential to entitle a medical man to maintain an action for *attendances* and *medicine* that he should be registered at the time when he gave such attendances and supplied such medicine, it is enough if he appears to be duly registered at the time of the trial, when he tenders proof of registration in evidence. Where a medical man is suing on a promissory note, given in consideration of professional services, it will be necessary for him to prove registration to entitle him to recover.

Where the chief medical officer of a foreign ship lying in the Thames engaged a foreign medical practitioner, domiciled and practising in England but unregistered, to take charge of the sick soldiers and sailors of that vessel (some of whom were on board that vessel and some on shore) during *his temporary absence abroad*, at a fixed monthly sum, it was held that the *unregistered practitioner could not recover* on such contract, for that the defendant, when he went abroad, was in the situation of an ordinary paymaster, and not the less so because *he happened to be a medical man*, and *although* the contract was made on board a foreign ship, yet by whatever law the contract was to be interpreted the remedy must be governed by the *lex fori*.

A copy of the Medical Register for the time being, purporting to be printed and published under the direction of the General Medical Council, is evidence in all courts that the persons therein specified are registered according to the provisions of the Medical Acts. In the case, however, of any person whose *name does not appear in such copy*, a certified copy under the hand of the registrar of the General Medical Council, or of any branch council, of the entry of the name of such person in the general or local register is evidence that such person is so registered.

between 100 and 200 miles, about $1\frac{3}{8}$d. per gallon; and 200 miles and over, about $2\frac{3}{10}$d. per gallon.

What can be done in the State of New York could, it appears to me, be done in England. The difference of prices ought not to be an insuperable difficulty, for the present methods are not economical, and the same profits might be made by all concerned in the milk trade that are made now, after the removal of the obvious drawbacks of the existing system, or want of system, of which London in particular complains. Milk cans before they leave the dairy farms from which they are sent should be locked or sealed. This would not add to the cost of the milk appreciably. In a short time it would become a matter of routine on which practically no time would be spent. Whatever leads to the decanting of milk on railway platforms should be altered. The custom is absolutely dangerous and ought to cease at once. The number of special milk trains should be increased. The practice of carrying milk in the guards' vans of passenger trains should not be permitted. Some of the milk vans used by certain of the railway companies for bringing milk into London did not appear to me to be very well adapted for the purpose, but any special van, receiving special attention, is better than a guard's van or a luggage van. Passenger guards' vans which are used as milk vans by some railway companies are not adequately ventilated; they cannot be fit for the milk service if the weather be hot and the distance to be traversed be long. Perhaps in these circumstances they are never used, but if it was a uniform custom to convey all milk in a sanitary manner economy would result. Neither are open-boarded vans quite suitable for carrying milk for the reason that wet and dirt are easily admitted. As to the employment of refrigerating apparatus in milk vans, the general opinion seems to be that the distance which milk is carried by rail in England is not sufficiently long to render such a procedure necessary. Moreover, the use of chilling methods is becoming common in the larger dairies and is not, I believe, very expensive. When this is done milk can be carried in hot weather for long distances, and probably railways consider chilling a valuable precautionary measure to take against the risk of chemical change during transit, but here again a uniform method of refrigeration would be preferable. Chilling may be done at some dairies and not at others, but if all milk were carried in milk trains and kept artificially cool the risk of chemical change could be diminished to the vanishing point. Refrigeration in the railway train might possibly be done away with if the milk can was protected by means of a cover or outside lining made of some efficient non-heat-conducting material. The question of refrigerating milk while in transit on the railways in this country is, of course, of far less importance than in those countries in which the climate is warmer, and in which milk must be transported by rail for long distances. Nevertheless, many authorities are of the opinion that the subject is deserving of closer attention than has been paid to it hitherto. Dr. W. Collingridge, medical officer of health of the City of London, has stated emphatically that among other much-needed improvements tending towards the safeguarding of the milk-supply railway companies which carry milk should be compelled to provide special refrigerator vans for the purpose. Refrigerating methods are largely employed now in all the large dairies and milk should be chilled and kept at a proper and equable temperature from the time it leaves the dairy farm until it reaches its destination. Refrigerating vans can be provided at no great expense. If the railway companies found that there was a widespread demand on the part of the general public that refrigerator vans should be provided for the carriage of milk then such vans would be soon supplied.

The railways would probably have something to say as to the increased expenditure and might desire to raise the rates of carriage somewhat. But the rates charged for conveying milk to London, according to many of the farmers, are too high, while the railway companies contend that they are extremely moderate. The same rate is charged for milk transport by all the railways running into London—viz., 1d. per gallon. This rate compares favourably with the rate charged in the eastern part of the United States, but the milk there fetches a higher price. To the ordinary observer it seems probable that the railway rates are not much to blame. No one argues that the vendors of milk are specially oppressed and no one can contend that English railways are amassing large fortunes for their shareholders. What is probably to blame is the lack of system.

Is it foolish to hope that soon we shall see all our metropolitan milk conveyed in special trains to special sidings in circumstances that make contamination or chemical change well-nigh impossible? And would it not be well if the London County Council were to look into the American system of milk stations on the railways, where milk could be received from the farmer of the locality, kept in a proper manner, handled in a proper manner, and placed in a proper manner upon the special trains. I do not believe that such an orderly way of doing things would end either in the price of the milk going up or in the profits of the farmer, the purveyor, or the railway going down.

THE BASLE MODEL MUNICIPAL ABATTOIR.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE ancient town of Basle is familiar to many tourists who annually travel to Switzerland, though most persons content themselves with changing trains at its busy junction station. Basle is an important historic and cathedral town and has a population of close upon 100,000 inhabitants. It is situated on the banks of the Rhine and in the point of an angle or wedge of land thrust in between Alsace and the Grand Duchy of Baden. Thus German territory is within sight and an easy walk from Basle. Perhaps this proximity may help to account for the fact that at Basle the best and most novel German devices have been adopted in the newly built municipal slaughter-house. Indeed, it is not a long journey down from Basle to Mannheim or to Offenbach, which towns possess public abattoirs that are renowned throughout the world for their excellent installation. In Switzerland there have been public slaughter-houses, at least for the larger animals, for more than 200 years. At the present time it would be difficult to find a locality with more than 2000 inhabitants which has not its public slaughter-house. On the other hand, it must be confessed that many of these are very roughly built and have appliances of a very primitive description. Nevertheless, there is generally a veterinary surgeon in the neighbourhood who is supposed to control these places. Moreover, Article 31 of the Fundamental Laws of the Swiss Confederacy authorises the communes as a sanitary measure to render the use of the public slaughter-house obligatory. Some of the slaughter-houses have been built partly at the cost of a syndicate of butchers and partly out of the proceeds of local taxation. But in the larger towns—at Zürich and notably at Basle—modern slaughter-houses have been erected which may well serve as models for all countries.

A public slaughter-house was built at Basle in 1870. It yielded a sufficient income to provide the annual contribution of 5 per cent. to the sinking fund. When the loan was paid off the desire was felt to reconstruct and to introduce cold storage—in fact, to have a perfect abattoir. To a large extent the experience of the town of Mannheim served as an example. The new Basle municipal abattoir was completed in 1903. The date, it will be seen, is sufficiently recent to admit of the introduction of the best and most modern improvements. Also the entire management is placed in the hands, not of commercial men, but of Dr. B. Siegmund, who administers according to the scientific and humanitarian point of view and not with a commercial object. The director of the Basle slaughter-house is an eminent member of the Society for the Protection of Animals, and in 1893 he made a present of his invention for the humane killing of animals to the society. Thus it is now public property, Dr. Siegmund having refused to make money out of what he contrived for humanity's sake. His object being to prevent pain, he considered that it would not be right to hinder the rapid diffusion of the system by adding to the cost a royalty for the inventor. Doubtless, the heads of abattoirs generally with their commercial instincts would look upon the director of the Basle abattoir as an incomprehensible Don Quixote not to accept any payment for a really ingenious and useful invention. But it is just because a truly scientific man places a scientific object far and above commercial interests that great institutions such as public abattoirs where the public health is held in trust should be governed by professional men whose objects and ideals are not tainted by financial considerations. These gentlemen

THE BASLE MODEL MUNICIPAL ABATTOIR.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE ancient town of Basle is familiar to many tourists who annually travel to Switzerland, though most persons content themselves with changing trains at its busy junction station. Basle is an important historic and cathedral town and has a population of close upon 100,000 inhabitants. It is situated on the banks of the Rhine and in the point of an angle or wedge of land thrust in between Alsace and the Grand Duchy of Baden. Thus German territory is within sight and an easy walk from Basle. Perhaps this proximity may help to account for the fact that at Basle the best and most novel German devices have been adopted in the newly built municipal slaughter-house. Indeed, it is not a long journey down from Basle to Mannheim or to Offenbach, which towns possess public abattoirs that are renowned throughout the world for their excellent installation. In Switzerland there have been public slaughter-houses, at least for the larger animals, for more than 200 years. At the present time it would be difficult to find a locality with more than 2000 inhabitants which has not its public slaughter-house. On the other hand, it must be confessed that many of these are very roughly built and have appliances of a very primitive description. Nevertheless, there is generally a veterinary surgeon in the neighbourhood who is supposed to control these places. Moreover, Article 31 of the Fundamental Laws of the Swiss Confederacy authorises the communes as a sanitary measure to render the use of the public slaughter-house obligatory. Some of the slaughter-houses have been built partly at the cost of a syndicate of butchers and partly out of the proceeds of local taxation. But in the larger towns—at Zürich and notably at Basle—modern slaughter-houses have been erected which may well serve as models for all countries.

A public slaughter-house was built at Basle in 1870. It yielded a sufficient income to provide the annual contribution of 5 per cent. to the sinking fund. When the loan was paid off the desire was felt to reconstruct and to introduce cold storage—in fact, to have a perfect abattoir. To a large extent the experience of the town of Mannheim served as an example. The new Basle municipal abattoir was completed in 1903. The date, it will be seen, is sufficiently recent to admit of the introduction of the best and most modern improvements. Also the entire management is placed in the hands, not of commercial men, but of Dr. B. Siegmund, who administers according to the scientific and humanitarian point of view and not with a commercial object. The director of the Basle slaughter-house is an eminent member of the Society for the Protection of Animals, and in 1893 he made a present of his invention for the humane killing of animals to the society. Thus it is now public property, Dr. Siegmund having refused to make money out of what he contrived for humanity's sake. His object being to prevent pain, he considered that it would not be right to hinder the rapid diffusion of the system by adding to the cost a royalty for the inventor. Doubtless, the heads of abattoirs generally with their commercial instincts would look upon the director of the Basle abattoir as an incomprehensible Don Quixote not to accept any payment for a really ingenious and useful invention. But it is just because a truly scientific man places a scientific object far and above commercial interests that great institutions such as public abattoirs where the public health is held in trust should be governed by professional men whose objects and ideals are not tainted by financial considerations. These gentlemen ails enables the easy transference of the meat, either o be delivered to the butchers' carts outside or to the cold storage rooms that are close at hand. Here there are large cages with lock and key which butchers can hire at a rental of £10 per annum and keep their meat safely till it is wanted. There are, of course, registering dry and wet bulb thermometers. The thermometer on the day of my visit marked six-tenths of a degree Centigrade below freezing point. Here, as elsewhere, I noticed no odour save that of fresh meat. To realise how this low temperature is maintained throughout the summer it is necessary to visit the splendid boiler-house and engine-house. The power obtained is used to compress carbonic acid gas till it becomes liquid. Then when this is allowed to evaporate through pipes that are immersed in salt water the liquid is reduced to a temperature considerably below zero. The refrigerated salt water is then allowed to fall as a shower-bath in a room where air is collected to feed the entilators. The dust is washed out of the air by the hower-bath and its temperature is lowered to about 3° elow zero Centigrade, and the moisture in the air falls to he ground as snow. Thus a dry and cold air is obtained and entilating fans propel it along shafts to the cold storage ooms. Other fans draw the air out from the cold storage oom so that it may be washed and cooled again and mixed ith a fresh supply of outside air. When the outside air is ery damp then only a smaller quantity of it can be em-loyed. In the engine room there is an observation instrument which records at all times the state of the temperature n different parts of the building. From this centre the emperature is regulated throughout. The enormous advan-age of these scientific and mechanical appliances is that they render the whole process of slaughtering, of preparing, and of preserving meat independent of climatic considerations. The weather may be hot or cold, wet or dry, but the meat while at the Basle slaughter-house will not be affected by these atmospheric fluctuations.

(To be continued.)

SOME TURKISH LAZARETS

AND OTHER SANITARY INSTITUTIONS IN THE NEAR EAST.

BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.

With Reproductions of Photographs taken by the Author.)

IV.[1]

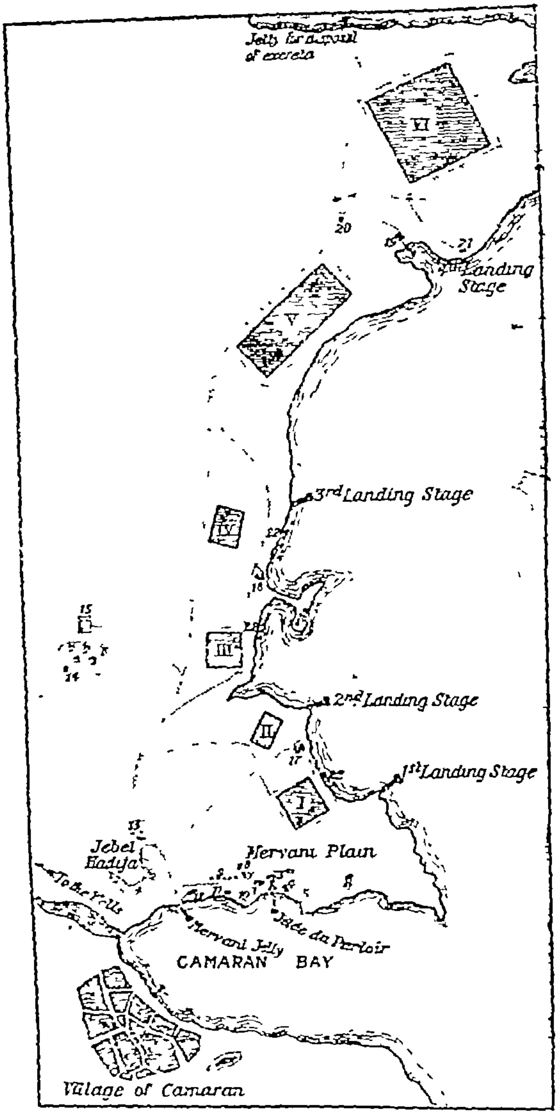
THE CAMARAN LAZARET (*continued*).

The Six existing Cordons: their Dimensions and Contents.—A New Kind of Fencing Proposed.—Kitchens.—General Plan of the Lazaret.—Its Proposed Concentration by transferring the Fifth and Sixth Cordons to other Sites.—New (Seventh) Cordon for Arrivals by Samboul.—The Numbers of Pilgrims for whom Accommodation will be provided.

As already stated, there are six camps or cordons. These are inclosures of various sizes surrounded by a fence and containing a varying number of arishes, the "hospital," "doctor's house," and "house of distinction" mentioned already, fresh-water cisterns, latrines, &c. The position of the six camps is shown in the first of the accompanying sketch-maps of the lazaret. They are widely separated from each other, so widely that the whole length of the lazaret, from south to north, is about five kilometres, or, roughly, three miles. This great and unnecessary extension of the lazaret leads to many disadvantages. The work of the staff is much increased; time is needlessly lost in getting from one part of the establishment to another; the more distant camps are rarely used and the upkeep of the buildings they contain is badly neglected; the length of the railway and of the fresh- and salt-water pipes is enormously increased; in a word, the whole institution, instead of being compact and concentrated and easily supervised from the administrative centre, is exactly the reverse. In addition, the great length of the lazaret adds seriously to the difficulties of excreta removal under the system (to be described later) now adopted and increases the risks of removing the seriously sick from the more distant camps to the central hospitals.

For these reasons the Commission urges the diminution of the total length of the lazaret by about half. This can easily be effected by abandoning the present fifth and sixth cordons (one of which, the sixth, is almost never used and the other rarely) and building a new cordon between the present third and fourth cordons, and another one to the north of the fourth cordon. There will thus still be six cordons. It will be necessary further to abandon the third disinfecting pavilion, or rather to transfer it to a spot near the land end of the third jetty (as described in an earlier article). The fourth jetty will also have to be abandoned, but this is of small consequence, because the jetty (as stated in Article III.) is useless in its present condition. Corresponding modifications would, of course, have to be made in the railway and in the water distribution. In the case of the latter there will be a saving of several kilometres of good iron piping.

PLAN II.



Sketch-plan of the Camaran lazaret in its actual condition. I. to VI., cordons for pilgrims 1, machinery building; 2 laboratory and "parloir"; 3, offices and residence of staff; 4, fresh-water reservoirs; 5, arishes for "gardes"; 6, director's bungalow; 7, store; 8, bungalow; 9, houses for employees; 10, vice-consul's house; 11, lady doctor's house; 12, coal store; 13, brick-fields, &c.; 14, Tomb of Sheikh Irakl; 15, hospital; 16, small pox sheds; 17, 18, and 19, first, second, and third disinfecting pavilions; 20, "hospital" of fifth camp; 21, "hospital" of sixth camp; 22, latrine jetties; ...... railway.

Each cordon is, as already stated, surrounded by a fence.

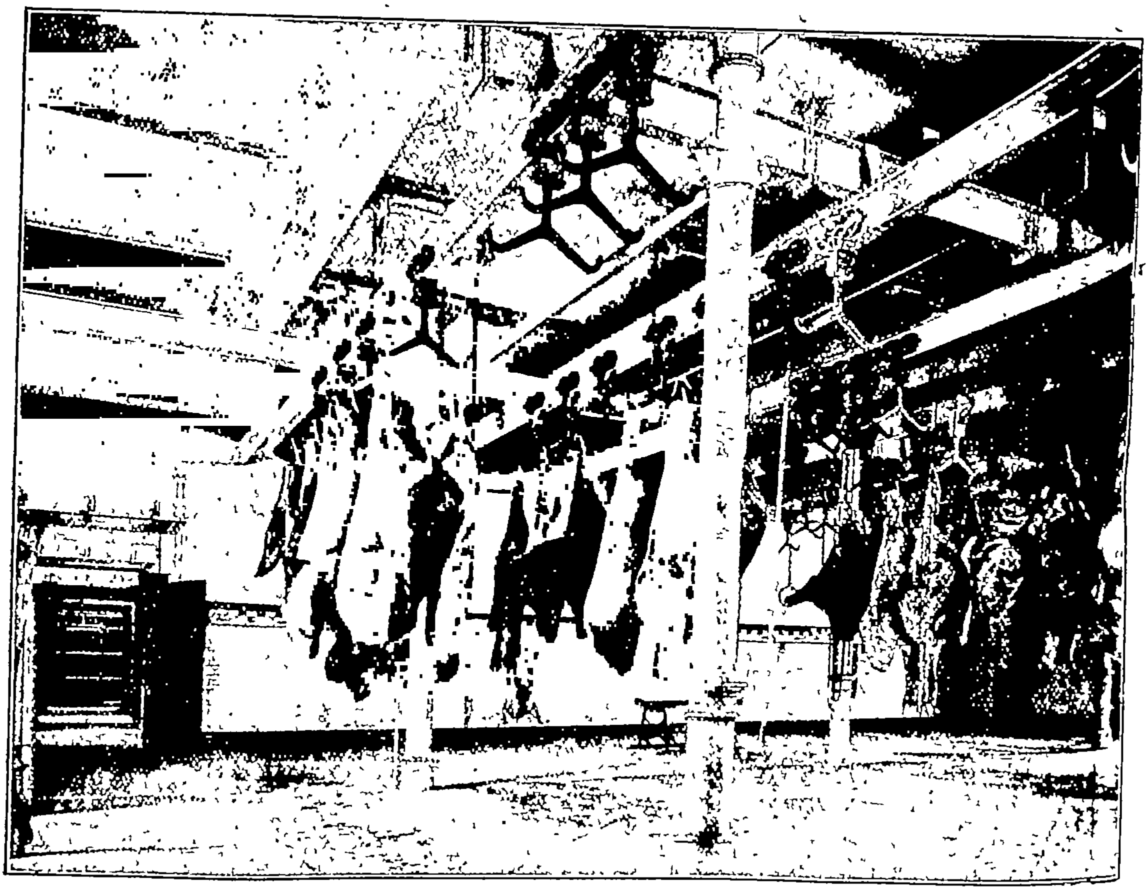
---

[1] Nos. I., II., and III. were published in THE LANCET of April 27th (p. [illegible]) and May 4th (p. 1251) and 11th (p. 1317), 1907, respectively.

should, of course, receive a sufficiently liberal honorarium to secure them from monetary worries and thus to enable them to devote their scientific attainments and their time solely to the public service.

At Basle in the slaughter hall for horned cattle there is room for dealing with 28 bullocks at one time. The animal is quietly conducted up to the spot where all is ready to deal with the carcass when the animal is killed. Then the Siegmund mask is applied to its forehead. This consists of a brass disc about four or five inches in diameter. When this is placed on a bullock's forehead so that the edges of the disc do not protrude on either side, the aperture in the middle is just over the centre of the brain. Above the disc there is a sort of pistol barrel which, however, expands in the shape of a cup before it reaches the disc. This is to provide space for the gases when the cartridge is fired. The bullet traverses the brain and generally reaches the spinal cord. Death is instantaneous. It never fails; the aim must be correct on account of the size and shape of the disc. Fulminating cotton—that is, the official Swiss smokeless gunpowder—is used and the explosion makes very little noise. There is no need to tether the animals or, as when the mallet is used, to hold the animal's head down in a favourable position. The slaughterer quietly and gently places the smooth disc on the unsuspecting animal's forehead and the next moment it falls as if struck by lightning. Only men employed and paid by the municipality are allowed to slaughter. They are not urged to work quickly but in every way to prevent any unnecessary suffering.

FIG. 3.



The Basle municipal abattoir. The cooling passages, where carcasses are kept 24 hours before delivery to the butchers or consignment to the cold storage rooms.

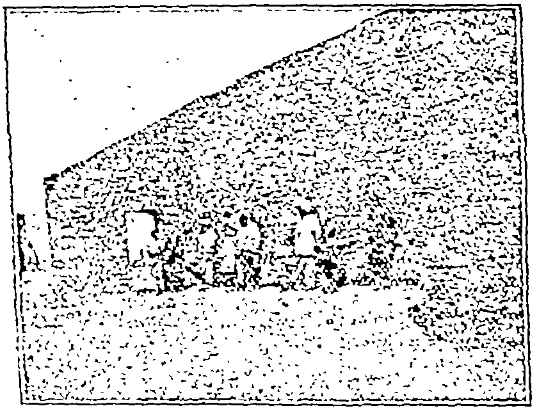
The Bruneau and other masks where a nail is employed have been found untrustworthy. They certainly do occasion some loss of time, for there is a great leather mask that has to be strapped across the animal's head. In the centre of this mask there is a loose nail held in a socket, and this is struck with a mallet so that it penetrates the brain just at the right spot. But this apparatus is liable to get dirty, then the nail fails to penetrate properly, and it cannot be easily withdrawn as the bone closes round it so that occasionally this method which is intended to insure a prompt and painless death proves a ghastly failure. Also it undoubtedly takes time to strap the mask on and to unstrap it afterwards. With the Siegmund pistol mask all this trouble is avoided and the animal falls just where its carcass is required to be. The flooring is of course absolutely watertight, being made with cemented flagstones. The walls all round and up to a considerable height are of bricks with porcelain surface cemented together and equally watertight and non-absorbent. Above there are a great multiplicity of rails and along the walls numerous hoists. It is only necessary to turn a handle and by an ingenious combination of cranks and cogwheels a heavy carcass can be promptly suspended. When ready the pulley runner and chain can be pushed along the overhead rails and the carcass goes from the slaughter hall to the cooling room. Close at hand are metallic receptacles for the offal and there are tables on wheels for any of the work which butchers have to do. Hose like a fire hose is ever ready for sluicing the floor, no dirt is allowed to remain, everything objectionable is at once cleared away. The most perfect cleanliness prevails throughout. On both sides there are windows but on the side where the sun shines a lozenge-shaped double glass pane is used. The space between the two panes is two to three inches wide. The advantage is that while letting the light through it excludes direct rays and heat. Thus a bright strong sunshine beating upon these windows barely raises the temperature 1° C.

Just outside this slaughter hall for the large cattle is what might be called the cooling passage which must not be confused with the cold storage or refrigerating department. The carcasses are allowed to hang for 24 hours in this passage. Here the temperature varies from 3 to 6° C. above zero. From this point an unbroken succession of overhead were put in it but in both of the last two pilgrim seasons it has remained wholly unoccupied.

Besides the objects already mentioned most of these cordons contain a small arish for the head-guard (*chef garde*) and in some is an arish used as a mosque. A *bacal*, or seller of groceries and other articles, is always established in each cordon, sometimes in a tent, sometimes in an empty arish or elsewhere. The Commission recommends the construction in each cordon of a small special arish for the *bacal* and his store.

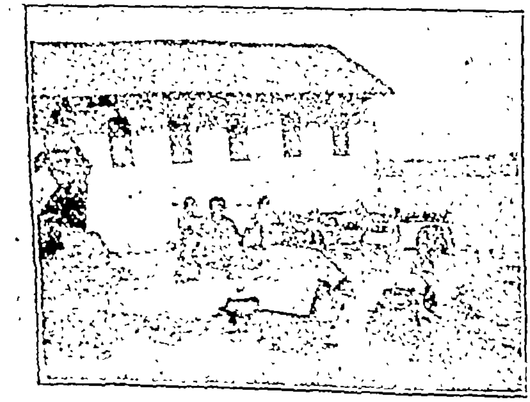
In each of the first four cordons there is a masonry structure intended to serve as a kitchen. It is composed of a wall 12 metres long and 5·60 metres high; at each end is another wall at right angles, so that the whole resembles a rather flattened capital H. Along both sides of the central wall are rows of brick fire-places. The arrangement is fairly well shown in Fig. 12. In the first cordon the whole structure has been roofed in and surrounded by matting walls. This kind of kitchen has many drawbacks; the enormously high middle wall gets intensely hot with the heat of the fires and of the sun; it is even worse in the first cordon, where the matting roofs and walls, though they shade from the sun, prevent free escape of the smoke. The Commission considers that there is, as a matter of fact, no need to build costly structures of any kind as kitchens. Most of the pilgrims carry with them small portable "kitchens," such as those seen in Fig. 13; those who have not are quite content to build a fire over a hole in the sand on two or three bricks, or in some other equally primitive but effective manner.

FIG. 12.



View of kitchen.

FIG. 13.



Pilgrims cooking their food on portable "kitchens."

The general plan of the lazaret.—Having studied the unit (the pilgrims' houses), and the arrangement of these units in cordons, it will be convenient now to speak of the general plan of the lazaret. It consists, as already stated, of the so-called "central" administrative buildings and of the six cordons. The former are not really central at all, being built at the southern extremity of the whole institution. This is regrettable in some ways, as it would be much easier to supervise the whole were the administrative blocks somewhere nearer the centre. But this would be almost impossible of attainment now. The present plan has been a natural growth; the offices had to be near the landing stages in the bay; the central reservoirs for the water-supplies had to be at the same time near the sea (for the intake) and on high land (to get sufficient pressure), and these conditions are only found on the northern shores of the bay. The present plan therefore (that is, six cordons in a row and the administrative buildings at one end) will be more or less retained. But the drawbacks inherent to such a plan will have to be diminished as much as possible. As the Commissioners state in their report, one extremity of the lazaret suffers from a grave anæmia, if not an irremediable gangrene, on account of its distance from the heart of the institution; and as the heart cannot be moved nearer the extremity the latter must be brought nearer the heart. In other words, the cordons must be concentrated. The manner in which this can be done has been already indicated. The fifth and sixth cordons must be abandoned, others being built between the third and fourth, and to the north of the latter, to take their places; and as a corollary the third disinfecting block must be transferred to the spot already indicated and the necessary modifications made in the landing-stages, railway, and water-supplies.

The lazaret as it will be after these works have been carried out is shown in Plan III. It will be seen that the general symmetry of the institution will in no way suffer, while in compactness and in every other respect it will gain greatly. The two new cordons will be of about the same dimensions as the existing first camp. It is proposed to arrange the new sixth cordon in a special manner for the reception of pilgrims from an actually infected ship.

In addition to the six cordons, so frequently mentioned above, the Commission proposes to have a seventh, to be reserved for arrivals by sambouk or other kind of sailing ship. These arrivals are rarely numerous and it will suffice to provide a small cordon capable of holding a maximum of 250 pilgrims. A good site exists a little to the south of the first cordon and it is here that the Commission proposes to set up the new cordon. Hitherto arrivals by sailing ships have been placed under tents and in no properly fenced-in cordon. This, which is, to say the least of it, irregular, will now be remedied.

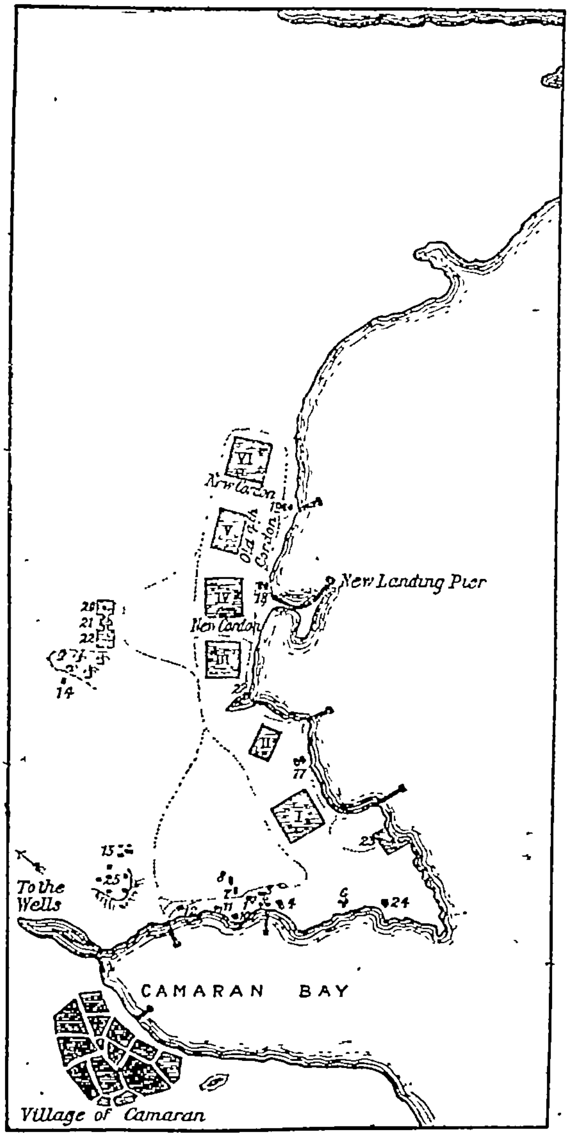
A word may be said here as to the numbers of ships and of pilgrims usually in quarantine at a time in Camaran. The Commission has prepared and annexed to its report five large diagrams, showing in a graphic manner the daily movement of the lazaret during each of the last five pilgrim seasons. In these diagrams there are thin vertical lines to show each day of the year, and the stay of every ship in the lazaret is shown by a horizontal thick line, beginning on the day of the ship's arrival and ending on the day of her departure. In this way it is possible to see at a glance how many ships were in quarantine simultaneously on any given date; and the number of pilgrims being inserted against each horizontal line a simple sum in addition suffices to show the total number of pilgrims in quarantine at any moment. From these diagrams it appears that there are very rarely more than six ships at Camaran at a time. Occasionally there have been seven, eight, and even nine, but when this has happened it has usually been for only a few hours and experience has shown that the six large cordons are practically sufficient. In the five years in question (in two of which the pilgrimage was exceptionally largely attended) the total number of pilgrims interned at the same time reached at one moment 6499. For most of the time the total rarely exceeded 5000 and was usually much less. With the six large cordons and the small one for arrivals by sambouk the lazaret will be able to hold 6550 pilgrims, as shown in the following table:—

First cordon	1200	pilgrims.
Second cordon	720	"
Third cordon	1200	"
Fourth (new) cordon	1200	"
Fifth (actual fourth) cordon	780	"
Sixth (new) cordon	1200	"
Small cordon for arrivals by sambouk ...	250	"
Total	6550	

The present year's pilgrimage is likely to be one of the

It is composed of thin wooden laths and is of the most unsubstantial character. In some camps (notably the fifth and sixth) it has tumbled down in parts or disappeared and not been replaced. It is clear that such a barrier has no real effect in keeping the pilgrims inside their cordons. All it can do is to serve as an indication to the pilgrims of the limits to which they are confined. Most of them it is probable have little desire to go beyond those limits; they are strangers to the island and to its native inhabitants and it is said that they rarely, if ever, try to escape from their camp. But it is certain that the "gardes" engaged in the Camaran village and interned with the pilgrims can, and it is probable that they do, communicate freely with their friends in the village. Moreover, should cholera or plague break out in a cordon there would be considerable temptation to the pilgrims to try to escape to other cordons. In any case "isolation" cannot be regarded as guaranteed with the present flimsy fencing; and the Commission proposes to surround each of the cordons at Camaran with a fencing similar to that adopted at Tor. This is composed of strong galvanised iron wire netting two and a half metres high, supported on wooden posts fixed in the sand; above the netting there are two or three rows of barbed wire and at its base a series of wooden planks running all round the cordon to prevent the pilgrims digging in the sand and creeping under the lower edge of the netting. This form of barrier is said to have given very satisfactory results at Tor.

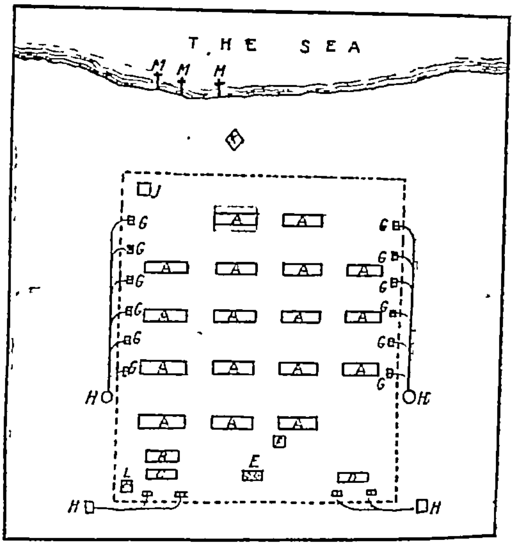
PLAN III.



Sketch-plan of the Camaran lazaret as modified by the proposals of the Commission. The figures indicate the same buildings as in the preceding plan, with the following exceptions: 19, third disinfecting pavilion on its new site; 20, inclosure for hospital for infectious diseases; 21, inclosure for small disinfecting pavilion; 22, inclosure for hospital for ordinary diseases; 23, new cordon for arrivals by sambouk; 24, new house for medical staff; 25, new houses for employees.

The six cordons vary greatly in size. The first cordon is 167 by 150 metres and thus contains 25,050 square metres of surface. It lies on the shores of a bay, quite close to the sea, and but little raised above it. The ground plan of this cordon is shown in the accompanying sketch (Plan IV.). It contains 16 old-type arishes and one new type; the three "pucca" houses mentioned above; kitchen; 16 huts, with two water-closets in each; two fresh-water cisterns; salt-water tank or tower (as in all the other cordons), &c. There is room for three more arishes, bringing the total to 20, which would enable this cordon to lodge up to 1200 pilgrims.

PLAN IV.



The Camaran lazaret. Plan of the first cordon. A A, Arishes. B, Sorting-house. C, Medical officer's house. D, Hospital. E, Cisterns. F, Kitchen. G G, Huts for w.c.'s. H H, Sewer-ditches. J, Superintendent's arish. K, Mosque. L, Water-tower.

The second cordon measures 150 by 104 metres and has 15,600 square metres of surface. It is situated on sloping ground, rising at its highest to several metres above sea level. It contains ten old-type arishes; two more could be added, which would enable this cordon to hold 720 pilgrims.

The third cordon measures 170 by 157 metres and has 26,690 square metres of surface. Like the first camp, it lies very low and is liable to inundation. It contains 19 arishes (18 old type and 1 new type); a twentieth could be added and this cordon could then lodge 1200 pilgrims.

The fourth cordon (482 metres to the north of the third) is 152 metres long and 130 wide, its superficial area being thus 19,760 square metres. It lies some 220 metres from the sea, on an elevated plateau which extends from here to the northern limit of the lazaret. It contains 10 arishes, all new type; two more could be added, and, as this cordon contains also the "specimen house" above described, it could lodge in all 780 pilgrims.

The fifth cordon lies no less than 772 metres to the north of the fourth; its length is 505 metres, its breadth 186, and its superficial area is thus 93,930 square metres. It is simply a vast area of desert, inclosed by a partly broken-down fence, and containing six old arishes and four new ones.

The sixth cordon is even vaster than the fifth, from which it is separated by a distance of 668 metres. It is 360 metres long by 330 wide, which gives a surface of 118,800 square metres. In this great square of desert there are no arishes; indeed, nothing is to be seen save the doctor's house and house of distinction, and 16 huts for water-closets. The "hospital" has been built on a cape 300 metres outside the camp. The fencing and the railway which once ran round the cordon are in a sad state of decay. This camp is almost never used; once in 1902–03 and once in 1903–04 pilgrims ie case of a working man with a family dependent on his xertions for a livelihood it cannot be wondered at that he dread day is too often postponed.—Mr. William rosfield (the vice-chairman) drew attention to the fact hat last year's tobacco bill for aged inmates at the iverpool workhouse amounted to £906, and he expressed he fear that this liberality on the part of the workhouse ommittee in the matter of the soothing weed had a tendency to attract many old men to the workhouse who otherwise would not be anxious to seek refuge within its walls. As only inmates of over the age of 60 years are entitled to the luxury Mr. Crosfield's view in the matter failed to meet with the endorsement of his fellow members.

University of Liverpool: New Lectureships.

Dr. W. H. Broad has been appointed lecturer in physical anthropology and Mr. J. K. Catterson Smith assistant lecturer and demonstrator in electro-technics.

Lancashire County Council; Health of the County; The Midwives Act; Extraordinary Food for Infants.

The chairman of the public health committee said that the death-rate of the county was higher than it had been for some time in consequence of the prevalence of respiratory diseases and influenza. 12 cases of small-pox had been notified during the quarter, against 23 in the previous quarter. The county had not been free from small-pox for two years and he thought that it was time it was. Five deaths had occurred from "spotted" fever, but judging from the report of the medical officer there was no reason for fear on that account. The report of the Midwives Act committee showed that the number of certified midwives on the county register on March 31st was 1081. The number of women qualified by examination was gradually increasing. Several cases of negligence or misconduct had occurred during the past quarter and the committee had instructed the medical officer of health to communicate with the midwives concerned drawing their attention to the necessity of a strict compliance with the rules of the Central Midwives' Board. Attention was drawn to the appalling ignorance prevailing regarding the feeding of infants. There was one case in which an infant, one month old, was fed on beefsteak and liver. The child died. Another infant of nine weeks was given black-pudding and whisky and a week later rabbit-pie, and still survived, "a monument of the inherent strength of the British constitution."

Health of Liverpool: Not Free from Small-pox.

The death-rate last week was 19·4 per 1000, as against 27 per 1000 a year ago. The fall in the death-rate appears to be due to fewer cases of measles and whooping-cough. There were 541 cases of infectious diseases in the corporation, including seven cases of small-pox. As Liverpool is probably the best vaccinated city in the kingdom there need be no cause for alarm on account of the occurrence of those cases.

Appointments at Chester Infirmary.

At a meeting of the election committee of the infirmary held last week Dr. E. Cyril Dobie was appointed honorary assistant surgeon and Dr. A. Douglas Hamilton, honorary assistant physician.

May 14th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

A Proposed Joint Appointment of Medical Officer of Health in Monmouthshire.

A CONFERENCE has been called of representatives from the urban district councils of Abercarn, Abertillery, Bedwellty, Ebbw Vale, Nantyglo and Blaina, Tredegar, and Risca in Monmouthshire, and of Brynmawr in Breconshire to consider the practicability of appointing a medical officer of health who should act jointly for these districts which adjoin each other and are situated on the western boundary of Monmouthshire and in Breconshire. The population of these districts at the last census was 114,000 and it is now about 140,000. The area is 46,000 acres. The combined salaries of the present medical officers of health amount to just over £400 a year. They are all in private practice. In the event of a combination being effected it is to be hoped that the Local Government Board will not sanction the payment of a commencing annual salary of less than £600, and that an adequate sum will be given for expenses caused by travelling about the district.

Sanitary Inspection in Bridgend.

It was not until the ravages of the typhoid fever epidemic in 1905 had emphasised the necessity that the Bridgend urban district council acted upon the advice of its medical officer of health, Mr. Wyndham Randall, and appointed an assistant inspector of nuisances, who was instructed to make systematic examinations of house drains. The justification for his appointment is seen in the fact that out of 605 houses inspected notices were served with respect to unsatisfactory drainage in 505. The district council will be well advised if it makes this appointment a permanent one. It ought not to be lulled into a sense of false security owing to the very favourable records for the year 1906. In that year there were only four cases of typhoid fever, and these were all non-fatal, compared with 117 and 16 deaths in 1905. Bridgend has a population of about 7000 persons.

Unqualified Dental Practice in Cardiff.

Cardiff can hardly be described as a happy hunting-ground for unqualified dentists. A few months ago one of these gentlemen was fined by the stipendiary magistrate for holding himself out as a qualified practitioner. The magistrate held that as the defendant in the case advertised that he extracted teeth painlessly he therefore ascribed to himself very special skill and the general public would consider him to be regularly qualified to practise. Quite recently another unqualified practitioner was sued in the county court for damages. The patient who brought the action asserted that several of her teeth had been so unskilfully extracted that she had not only already suffered great pain and inconvenience but would probably continue to do so for some time. The county court judge gave her damages to the amount of £25. A very unsatisfactory feature in this case was the admission by a young woman that she was a paid tout and had introduced the patient to the defendant.

Sewage of Bath.

The Bath corporation has very prudently decided to admit that the sewage of the city enters the river Avon and to consider the best method of dealing with the sewage in order to prevent the pollution of the river. The threatened proceedings of the county council under the Rivers Pollution Act will therefore be postponed indefinitely.

Insanity in Herefordshire.

The spring meeting of the south-western division of the Medico-Psychological Association was held at the Hereford County Asylum, when the medical superintendent of that institution, Mr. C. S. Morrison, read a most instructive paper upon the increase of insanity in agricultural districts, with special reference to the county of Hereford. After commenting upon the large amount of migration from the county, leaving as stay-at homes persons characterised by inertia, apathy, and but little capacity for sustained effort, he pointed out that Herefordshire held a unique position as regards the marriage-rate, for in 30 years this rate had remained stationary, whereas in all the counties of England and Wales except four it had fallen. In England and Wales the legitimate birth-rate had fallen from 292 per 1000 married women at conceptive ages in 1870 to 223 per 1000 in 1905. In Herefordshire during the same periods the legitimate birth-rate had fallen from 285 per 1000 to 223 per 1000, showing in conjunction with the unaltered marriage-rate that the fertility-rate in Herefordshire was considerably below that in other parts of the country. Reference was also made by Mr. Morrison to the low rate of infantile mortality in Herefordshire, which had fallen from 131 per 1000 births in 1870 to 85 per 1000 in 1905, and he stated that the Commissioners in Lunacy for Scotland had found by an analysis of the figures for the census year 1901 that the greatest number of congenitally deficient persons received into the district asylums of Scotland came from rural areas with the lowest infantile death-rate. The same condition has been found in Herefordshire, where the proportion of persons of unsound mind has risen from 35 per 10,000 of the population in 1871 to 55 per 10,000 in 1905. In England and Wales during the same period there was a rise from 21 per 10,000 to 32 per 10,000.

Royal United Hospital, Bath.

At a meeting of the committee of the Royal United Hospital held on May 6th it was stated that the late Dr. Thomas Jarvis Bennett, formerly of Tunbridge Wells, had most numerously attended for many years past owing to the removal of the five days' preliminary observation of Indian pilgrims before sailing from Bombay. It is possible, therefore, that this total may be slightly exceeded; in that event, the excess number of pilgrims will have to be placed under tents.

(To be continued.)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

SEVERAL valuable gifts and offers which have recently been made to the University were notified and accepted at a recent meeting of the council. The botanical museum has been enriched by the collection of fungi made by Dr. Charles B. Plowright of King's Lynn, which comprises between 4000 and 5000 species. This gift was offered by some "Friends of the University." The Rev. C. Owen Pickard, Cambridge, has presented a valuable collection of British spiders to the zoological museum. The collection includes 300 species of true spiders and a number of other arachnids. The zoological museum has also received from Mr. George Copely a collection of corals and shells from the Philippine Islands. This collection contains a large number of important, valuable, and rare specimens. Sir John Holder has offered £1000 to be used for the purpose of filling in, with stained glass, the fine window at the south end of the great hall in the new buildings; and the contractor for the Bournbrook Buildings, Mr. Thomas Rowbotham, has offered to provide a clock and chimes for the great tower which is in the process of erection. It is probable that the clock and chimes will cost about £2000.

The Ingleby Lectures.

Dr. Thomas Wilson, who has been appointed Ingleby lecturer for the year, delivered the first of his lectures on May 9th. He pointed out that the lectures were established in 1876 in connexion with the Queen's College and were intended to promote the advance of obstetric surgery and medicine, which were the branches of medical science with which Dr. Ingleby was intimately associated. He drew attention to the sound judgment and close personal observations shown in Dr. Ingleby's writings and pointed out that he was the first medical man to practise obstetric surgery in Birmingham. Dr. Wilson chose as the subject of his lectures Inflammations of the Uterine Appendages and he dealt with them mainly from the point of view of his personal experience at the General Hospital and in private practice. He classified the inflammatory affections of the organs mentioned in two groups, the catarrhal and the purulent, and he laid stress on the insidious nature of the onset in many cases, and more especially when it was associated with scarlet fever infection. He also drew attention to the long periods of quiescence not uncommonly associated with collections of pus in the female generative appendages, and he pointed out that the pus in these quiescent conditions was usually sterile. In his second lecture he is to deal with diagnosis and treatment.

Queen's College.

Queen's College, which has passed through many vicissitudes, is to be closed as an educational institution, at all events for a time. This is much to be regretted, for the institution has had a long career and it has been the means by which much good work has been done. It was initiated by a Birmingham surgeon, Mr. William Sands Cox, who induced his medical friends to establish a medical school. This was first housed in Temple-row and afterwards in Snow-hill, and by the efforts of the Rev. Dr. Warneford a theological faculty was established. In 1843 the foundation-stone of a new home in Paradise-street was laid and in 1845 a Royal Charter was granted to the institution under its present name. Its fortunes varied, and in 1892 the medical school was removed to Mason's College whilst Queen's College became a purely theological institution. A few years ago it was decided to reconstruct the college at a considerable cost and the present building was opened about two years ago. When the reconstruction was carried out it was hoped that the rents of the various sets of rooms and offices would form a valuable source of income; unfortunately, this hope has been delusive; and as the income has proved to be insufficient it is stated that the council has decided to close the educational portion of the college, and it is suggested that a considerable portion of the building should be let to the University as a residential hostel for students. This will probably be done and the University will thus have the opportunity of gaining experience in the management of a hostel for men before it decides to erect a building specially for the purpose.

The Open Spaces Association.

This association, which has already done much excellent work in securing air spaces for our somewhat crowded city, is now making an attempt to acquire 20 acres of the well-known "black patch" which lies on the boundaries of Birmingham and Smethwick. If the land is not secured now there is no doubt that it will fall into the hands of the builder and be covered with as many houses as the local by-laws will allow. It is to be hoped, therefore, that the association will be able to obtain the money that it requires, which appears to be a sum of £9000, for it is said that the owners, Messrs. Tangye and Messrs. Pilkington, will sell the land which the association wants for £10,000 and that each firm will give £500 towards the fund for purchase. If the association succeeds in acquiring the land it is probable that part of it will be used as a park, part as a playground, and some portion may be used for allotments.

Annual Report of the Public Analyst.

On the whole the report of Mr. Liverseege for the year 1906 cannot be considered satisfactory, for it appears that adulteration increased as compared with the previous year. The number of samples examined under the Sale of Food and Drugs Act was 1480 and of these 2·3 per cent. were adulterated with preservatives only, and 11 per cent. in other ways. The increasing use of adulterants affected milk as well as other foods, and of the samples taken 5 per cent. were found to be adulterated with preservatives, as compared with 3 per cent. in the previous year, the preservatives used being boric acid and formic aldehyde. It is possible that the new system of taking repeated samples has had something to do with the discovery of a larger percentage of cases of adulteration, for it is stated that in some shops the stranger purchasing butter receives butter, whilst margarine is given to the regular customers.

Bequests to Medical Charities.

By the will of the late Miss Sarah Maria Stokes of The Hawthorns, Edgbaston, £7450 are devoted to medical charities in Birmingham. Four hospitals are to receive £1000 each—i.e., the General, the Queen's, the General Institution for the Blind, and the Ear and Throat Hospital. Six will receive £500 each—the Children's Hospital, the Women's Hospital, the Eye Hospital, the Orthopædic Hospital, the General Dispensary, and the Birmingham and Midland Counties Idiot Asylum. The Royal Institution for the Deaf and Dumb is bequeathed £250 and the Skin and Lock Hospital £200. The General Hospital, the Queen's Hospital, and the Children's Hospital also benefit by the will of the late Mr. Alfred Hill of Hagley-road, under which they receive £50 each.

May 14th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Sanatorium for Tuberculosis at Heswall; Sceptical Guardians; the Paupers' Tobacco.

THE select vestry of the parish of Liverpool, at its meeting on May 7th, appointed four representatives upon the committee of the Liverpool, West Derby, and Toxteth Park joint hospital for tuberculous patients at Heswall. It appears that a number of the members of the vestry are sceptical as to the value of the benefits of the hospital. They affirm, and not without reason, that many of the patients are in the last stages of the disease before seeking admission to the institution. The experiment is a decidedly costly one and is a charge on the parishes to the tune of £2 8*s*. 3½*d*. per head per week. If the patients cannot be induced to enter the sanatorium in the early stage of the disease it seems obvious that it is a waste of the rate-payers' money to maintain an institution which hitherto has not been an unqualified success. The work might probably be of a more hopeful character if the sufferers applied for admission at a comparatively early stage of the disease. In upon Dr. Windle, President of the Queen's College, Cork, and upon the Right Rev. Monsignor Mannix, President of St. Patrick's College, Maynooth

Limerick District Lunatic Asylum.

At a meeting of the board of the Limerick Lunatic Asylum held on May 8th, Mr. E. D. O'Neill, resident medical superintendent, furnished his report of the working of the institution to the close of last year. There had been an increase in the number of patients, the highest number having reached 670, while the accommodation was intended for 550. He considered the increase largely due to intemperance and to the condition of the houses of the working population. It was unanimously agreed to have the report printed and circulated.

Royal College of Physicians of Ireland.

The annual presidential dinner of the Royal College of Physicians was held on May 9th, Dr. Joseph M. Redmond, the President, being in the chair. The Lord Lieutenant was present with many other distinguished guests, and the toast of "The Guests" was responded to by the Master of the Rolls and the Rev. William Delany, S.J.

House Sanitation in Belfast.

The deplorable condition of many houses in Belfast, as demonstrated in evidence submitted to the Health Commission now sitting as well as by the personal observations made by the members of that inquiry, has at last roused the public health committee, and at the weekly meeting of the latter body on May 9th it was decided, after hearing a report on the matter from the medical officer of health and from the chief officer of the house-cleansing department, to appoint a subcommittee to take into consideration the desirability of adopting the cleansing of houses fortnightly and to prepare by-laws and to advise as to the provision of ashbins and other matters associated therewith. Lord Shaftesbury (the Lord Mayor) raised the question as to the state of many of the back passages and said, in his opinion, it was most important that these should be seen to and put into such a condition as would enable them to be not only thoroughly cleansed but flushed regularly with a hose-pipe. This recommendation was then added to the resolution. It is deplorable to think that in Belfast it was not until 1902 that the systematic removal of refuse began. Previously to that the householders had actually to pay 1s. per load to have this done, and there can be no doubt that the very existence of ashpits (not frequently enough cleaned out), dirty back passages, and houses not properly cut off from the ground air and moisture has in the past been an immense cause of disease. By placing these facts clearly before the public the Health Commission has done immense good and has galvanised the health committee into facing problems which have been settled long ago in English and Scotch towns but which otherwise would never have been touched in Belfast.

Belfast Health Commission.

The Health Commission resumed its sittings in Belfast on May 13th when the assistant city surveyor and the executive sanitary officer were examined. The evidence of the latter showed how deplorable is the knowledge of the public health authorities as to insanitary houses in Belfast, for when the chairman of the Health Commission asked questions in reference to such dwellings actually inspected by members of the Commission the witness said that he had no knowledge of them or they had not been reported, whereupon the chairman said: "I want to impress upon you that there is no chance of remedying these evils if you have no knowledge of them, and if you have no knowledge of them how can the public health committee have knowledge of them? It seems to me that the whole organisation of your department requires reconsideration." Witness also said—in reply to the question, "What duties are there in which you do not regard yourself as subordinate to the medical superintendent officer of health?"—"In the laying of drains or describing how that work should be done I would not consult the medical superintendent officer of health," and he also said that there were some matters connected with public health in which he thought he was better informed than the medical superintendent officer of health. He gave the opinion that the medical officer of health should have his time more taken up with the stamping out of infectious disease, whereupon one of the Commissioners asked, "Is not one of the ways to stamp out infectious disease to keep the houses healthy?" to which he was obliged to answer in the affirmative. Such evidence clearly shows the value of one of the resolutions passed by the Ulster Medical Society, "That the medical officer of health should be sole head of a department in charge of the health of the city in all its branches."

The Tuberculosis Problem in Belfast.

In a new city like Belfast, where, as reported to the Health Commission, from 1895 to 1906 (that is, during 12 years) 12,562 people died from pulmonary tuberculosis, making a total of over 17,000 deaths from tuberculosis when added to those caused by the other forms of the disease, it is of the utmost importance that a clearly defined and well-thought-out plan for dealing with the question should be brought before the public, and one of the objects of the commission of experts at present sitting in Belfast is to suggest measures in order to solve this most pressing problem. Instead, however, of waiting a few months until the Commission issues its report, it appears that the public health committee of Belfast, entirely on its own initiative, is about to rush on a scheme, for at a meeting of the city corporation held on May 1st it was announced that a subcommittee of the public health committee recommended the taking of a house in Great Victoria-street for the purpose of a tuberculosis dispensary—in other words, the establishment of a central dispensary in Belfast with a medical officer whose duties would be to deal solely with consumptive patients. Now, as pointed out by a correspondent ("Watchman") in the Belfast papers, a dispensary is only one element in the solution of the tuberculosis problem and by itself is of very little use unless some measures are taken to deal with the patients who will go there anxious to have hospital treatment. Up to the present, though frequently pressed by the Irish Local Government Board, the Belfast public health committee has not erected a sanatorium and the negotiations which were going on between the committee and the Forster Green Hospital for Consumption have so far ended in nothing, so that to open a tuberculosis dispensary without arranging beforehand what will be done with the early and with the advanced cases is "futile" (as stated by a writer in the Belfast daily press), "as much so as was the adoption of the Act for notifying infectious diseases without having first built a fever hospital." But, further, the public health committee has never even settled the question as to whether pulmonary tuberculosis should be made a notifiable disease (voluntary or compulsory), and it has never thought it worth its while to consult the members of the medical societies who would try to guide the committee and keep it right in a matter of such great public importance to the city. The fact of the matter is, no harm can accrue if the public health authorities will only wait a few months until the Commission at present sitting in Belfast—which has had such revelations brought before it in part by evidence and in part also by its own personal investigations—has made its report on this and other problems. To attempt to rush things now before this Commission has had time to report will only complicate matters afterwards, will arouse the suspicion of the public, and will still more alienate the medical profession who have so little confidence in the present administrative capacity or specialised knowledge of the public health authorities of the city. It is to be hoped that the Local Government Board will refuse to sanction any plan put forward by the Belfast public health committee until it is shown that it is one which will grapple with all sides of a confessedly difficult problem, as well as conform to its suggestion that the public health authorities should have an advisory committee to guide them in trying to solve the problem of tuberculosis.

May 13th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Cost of Maintenance of the Anti-tuberculous Department founded by Dr. Albert Robin at the Beaujon Hospital.

Dr. Robin has kindly supplied some supplementary information concerning the expense of his anti-tuberculous scheme, an account of which recently appeared in THE LANCET. In 1905 the cost of drugs, including gelatin, had risen to 693 francs for 4133 attendances, or 0·167 franc for each attendance; in 1906 it reached 9775 francs for 5371 bequeathed the whole of his estate, subject to certain legacies and the life interest of his wife, to the institution. The chairman stated that this would amount to £20,000, and Dr. Bennett directed that the legacy should be devoted to the augmentation of the permanent endowment of the hospital. It was mentioned that this gift will in no way affect the effort now being made by the Mayor of Bath to extinguish the present debt of £6000 owed by the institution.

The Workmen's Compensation Act.

At the Frome (Somerset) county court, before his honour Judge Gwynne James, sitting as arbitrator, a pork butcher's assistant recently made a claim against his employer under the Workmen's Compensation Act. Evidence showed that in October, 1906, the applicant sustained a strain while lifting a heavy ham, and that in consequence of this he obtained medical advice and shortly afterwards was admitted as an in-patient to the Frome Hospital. Medical evidence showed that when the applicant was at that institution the diagnosis was made that it was a doubtful case of traumatic subclavian aneurysm. Evidence was also given by the medical witnesses who examined the applicant on April 24th and formed the opinion that he had no aneurysm but was suffering from nervous debility. After a hearing which lasted four hours his honour decided in favour of the applicant.

Bristol General Hospital.

A public meeting was held at the Bristol Guildhall on May 7th, under the presidency of the Lord Mayor, for the purpose of raising £18,000 for the greatly needed improvements which are being made at the Bristol General Hospital. It was announced that £13,116 have been already promised and it is hoped that the remainder, about £5000, will be obtained shortly.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Scottish Association of Medical Women.

A SPECIAL meeting of the Scottish Association of Medical Women was held in Edinburgh on May 11th, when a discussion took place on the remuneration of posts held by medical women. In the course of the discussion various cases were cited in which medical women were holding posts at insufficient salaries, and it was pointed out that there was a tendency on the part of public bodies as well as among private practitioners when opening posts to medical women to fix the rate of remuneration at a lower level than would be considered sufficient in the case of medical men. After considerable discussion a motion was carried to the effect that in the opinion of the association it was undesirable that women should accept posts at a lower salary than that offered to men previously holding the same, and that in the case of new posts the association considered it detrimental to the interests of the profession that such posts should be taken by medical women at salaries which would not be accepted by men. A discussion also took place on the desirability of forming a central information bureau for the benefit of women graduates in medicine and it was decided to appoint a committee to consider whether such a scheme was practicable.

Memorial to Principal Story.

At a meeting of the subscribers to the memorial to the late Principal Story held last week it was reported that the fund amounted to £10,000. It was recommended that in accordance with the strongly expressed wish of the relatives a memorial window should be erected in the Bute Hall at the University of Glasgow. The recommendation was approved by the meeting and it was agreed that the balance of the subscriptions should be handed to Mrs. Story and the Misses Story.

An Interesting Case of Anthrax.

A case of anthrax has occurred at Tulliallan which is giving arise to much interest in veterinary and medical circles. The animal involved was a cow which was found on post-mortem examination to have died from anthrax. As the cow was suckling a calf the effect of the mother's milk on the youngster is to be watched closely, in the hope of ascertaining the effect of an anthrax-infected cow's milk.

Cerebro-spinal Fever.

Two cases of suspected "spotted fever" have occurred at New Elgin. The patients are two young girls, aged ten and 17 years respectively. A case has occurred at Perth Barracks, the patient being a young man who only five weeks ago joined the army. The soldier, who belongs to Montrose, has been removed to the fever hospital, where he lies in a critical condition. A fresh outbreak has occurred at Forfar, two cases and one suspected case having been notified to the authorities. One of these, a young lad of 14 years, has since died in the County Hospital. On May 10th a boy from Cellardyke was admitted into the district infectious diseases hospital at Overstone, East Fife, suffering from "spotted fever." This is the first case that has happened in this district. Three deaths from cerebro-spinal fever have occurred in Dundee Royal Infirmary. The first case was that of a young ploughman hailing from Forfar. This patient had been attending at the out-department for some time, and towards the end of last week reported himself as usual. He then proceeded to visit a relative in Broughty Ferry where he was seized with illness and developed the symptoms of the disease. In the other two cases the victims were children. The distinctive organisms of the disease were found in all three cases.

Aberdeen Infirmary: Handsome Gift from Lord Mountstephen.

The Aberdeen Infirmary has again benefited by the generosity of Lord Mountstephen to the extent of £10,000. In 1902 he gave securities yielding £1000 annually, and to that this gift is supplementary in so far as an opportunity having arisen of extending that investment on favourable terms he has most generously provided the necessary funds. The managers are thus enabled to take advantage of the situation and the thanks of the community are due to the kindly benefactor of this useful institution.

A Remarkable Outbreak of Tuberculous Disease in a Highland Family.

Dr. John Macdonald, county medical officer of health of Inverness-shire, in his annual report draws attention to a remarkable outbreak of tuberculous disease which took place in the family of a crofter at Tarbert, Morar. This man had lived in the same house for 21 years. His household consisted of himself, his wife, and 12 children, whose ages ranged from two to 21 years. In April, 1906, the eldest girl, aged 21 years, came home from service with a suppurating finger, developed pulmonary symptoms, and died on May 26th from tuberculous meningitis. In November of last year, another daughter, aged 14 years, was found to be suffering from pulmonary tuberculosis. She died on Jan. 8th of this year. During the time that this girl was ill it was found that the father was suffering from suspicious lung trouble, that the mother was suffering from tuberculous disease of the ankle-joint and possibly of tuberculous disease of the abdomen, and that two other daughters, aged 20 and 10 years respectfully, and the baby had distinct signs of pulmonary tuberculosis. The baby died on Jan. 3rd, and the daughter aged ten years died on Jan. 10th, after an illness of three weeks. The mother was removed to the Western Infirmary, Glasgow, where she died. The father died at the end of February. Two other members of the family have developed pulmonary tuberculosis. There was no family history of consumption, no ill-health had occurred previously to April, 1906, and there was very little expectoration in any of the cases. The house consisted of two apartments, with stone walls, thatched roof, and clay floors; it was very damp but was kept in excellent condition.

May 14th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal University of Ireland.

THE Senate of the Royal University met on May 9th when the warrant under the Royal Sign Manual was read appointing Mr. Michael Finucane, M.A., C.S.I., to be a member of the Senate. On the motion of Dr. B. C. A. Windle, seconded by Dr. R. W. Leslie, it was unanimously agreed to re-elect Sir Christopher Nixon, Bart., as the representative of the University on the General Medical Council. On the unanimous recommendation of the standing committee it was resolved to confer the degree of LL.D. *honoris causa* racheotomies with a mortality of 46 per cent. The high figures for the tracheotomy mortality illustrated well the bad condition of the children who had to be operated upon. Among those classified as dangerously ill 287 children (44 per cent.) showed grave symptoms of stenosis of the upper air passages and were treated only with the serum and the steam chamber. The latter was a room into which all the intubated children were also taken, for the high percentage of moisture in the air was very beneficial in keeping the expectoration liquid and preventing the formation of dry masses in the trachea. Not a single case of so-called septic diphtheria made its appearance when the serum was employed. This very grave condition used formerly to be observed in 3 per cent. of all cases. As regards the diagnosis, it was better not to wait in doubtful cases until the result of the microscopic examination was obtainable, but to inject prophylactically. Furthermore, it must be kept in mind that there were plenty of instances known in which numerous Löffler bacilli were present without any clinical symptoms of diphtheria, whilst, on the other hand, negative results of the bacteriological examination were compatible with urgent symptoms of diphtheria. The rash after injection appeared mostly on the tenth day and was generally quite harmless; sometimes there was general malaise which soon passed away. As a rule 1500 units of antitoxin were sufficient the first time, but in very urgent cases from 2500 to 3000 units might be used. Paresis after injection was due not to the serum but to the diphtheritic toxin, and there was no case on record where death could be actually traced to the serum. As regards prophylactic injections Dr. Bittner has found that it was necessary that the friends of the little patients, their family, and all other children coming into close contact with them should receive injections, otherwise the patients might spread the disease, even after discharge from the hospital. For this reason 246 children were injected prophylactically during five years without a single case of infection occurring amongst them. A control experiment was made with three boys belonging to different families. These three boys had seven brothers and sisters who were not injected prophylactically and the result was that after the discharge of the patients all the other seven children contracted diphtheria within a short time. Furthermore, Dr. Bittner has made it a routine practice to inject a prophylactic dose in every case of operation for enlarged tonsils or for adenoids, since he has found that the reaction after the operation is markedly lessened and the after-effects of the operation, such as pyrexia and loss of flesh, are prevented. He thought that often in children the reaction after the operation was really due to a mild attack of diphtheria.

Death of Professor von Mosetig-Moorhof.

Professor von Mosetig-Moorhof, the distinguished surgeon, whose name became known all over the world by his introduction of iodoform for the treatment of wounds, met with his death in tragic circumstances a short time ago. He had of late been troubled by attacks of heart spasm and giddiness, and was in the habit of walking on the banks of the Danube, where the cool air and the stillness seem to have had a soothing effect on his nerves. The fatal accident appears to have occurred during one of his attacks of giddiness. He was seen to go down to the margin of the river where he wetted his forehead with water and then suddenly disappeared in the current. At that spot the river is over 500 yards wide and the current is strong. Several endeavours were made to save him but without success and his body has not yet been recovered. Although 69 years of age he was in fairly good health and his unexpected death came as a shock to his numerous friends and pupils. Of recent years his name was much mentioned on account of the "iodoform-plombe," as he called it—namely, a method of filling cavities in bones with iodoform, especially in cases of tuberculous disease; it has often given successful results and has been employed by rhinologists and other surgeons for disease of the antrum of Highmore. Professor von Mosetig-Moorhof had served in three wars as chief surgeon. He had, therefore, very large experience of this branch of practice and military surgery was with him a favourite subject upon which to lecture. The honorary posts held by the deceased were very numerous and his contributions to medical literature were highly esteemed. Apart from his professional work in the hospital, he was a very successful surgeon whose services were in much request.

Paying Wards in the General Hospitals.

The managing board of the Vienna hospitals, in the hope of replenishing the funds of these institutions, has devised a new scheme which from its nature is strenuously opposed by nearly 90 per cent. of the practitioners of the city. Judging, however, from other precedents it is to be expected that this opposition will only serve to confirm the board in its opinion. The intention is that a portion of the present general wards should be set apart for paying patients, to whom a charge would be made of probably from 5*s.* to 8*s.* a day. So far nobody would find any fault with the scheme. But the general practitioner originally in attendance is to be excluded from continuing to act as the medical adviser of the patient once the latter has obtained admission to one of these paying wards. This would mean a further diminution of the practitioner's source of income and would only serve to improve the position of the professors or directors of the clinic, who would alone be entitled to visit this class of patients in the hospital wards. A firm stand has been made by the Medical Council and all medical corporations on this point and vigorous protests have been sent to the managing board. Up to the present time, however, no result is visible.

Marmorek's Serum in Pulmonary Tuberculosis.

Dr. Fischer has used Marmorek's serum, administered per rectum in doses of from 5 to 10 cubic centimetres, for the treatment of 15 patients suffering from pulmonary tuberculosis. The result, as he said, when reading a paper on the subject before the Aerztlicher Verein, was not very encouraging. One patient became decidedly worse after one week, so that the treatment had to be stopped. The other 14 showed no ill effects due to the serum and, in fact, they improved to some extent as regards their weight and general condition, but the fever, cough, expectoration, and sweating were not influenced in any marked degree. All the patients were in the second stage of pulmonary tuberculosis, having infiltration of the lungs down to the second rib, moist râles, hectic fever, and loss of flesh and appetite. The favourable influence on the weight was explained by Dr. Fischer as being due to the improved hygienic conditions under which the patients were kept when in hospital. No subcutaneous injections were given, as has been recommended lately, nor were opsonic observations made. When Dr. Fischer found that even mild cases were not much benefited by a course of treatment lasting for three months he was not disposed to continue it.

(FROM OUR OWN CORRESPONDENT.)

The Marriage of Consumptives.

SOME ethical questions connected with tuberculous disease have recently given rise to considerable discussion in Hungary. Many medical men in this country ridicule the excessive anxiety of the public concerning the infectiousness of pulmonary tuberculosis and certainly the views expressed in the newspapers with regard to it are sometimes peculiar. A writer in a leading newspaper is at present urging that legislation should forbid the marriage of tuberculous persons, although he himself admits that this would be a very arbitrary proceeding and one likely to be opposed by public opinion. The medical press discountenances this proposal, though acknowledging that the mingling of tuberculous persons with the general population favours the extension of the disease. In regard to the question of the marriage of tuberculous persons the medical man is often placed in a difficult position and asked to undertake a very delicate task, but in spite of recent optimistic views respecting the inheritance of either tubercle or a liability to infection there can be no doubt that marriage of tuberculous persons or of those with marked constitutional predisposition to the disease should be discouraged.

An Unusual Case of Barlow's Disease.

At a recent meeting of the Royal Society of Physicians Dr. Grosz Gyula showed a case of Barlow's disease. The patient, who was a girl, aged 15 months, was fed from birth to the age of 12 months simply on boiled milk and afterwards she was given a mixed diet, consisting of soup, eggs, and meat. On this *régime* the child, it is stated, developed very well. Her first tooth came in her tenth month and she began to walk in her twelfth month. About six weeks previously her limbs began to be the seat of pain and to become swollen. On the two following days she suffered from attendances, or 0·181 franc per attendance. If general expenses be taken into account the total cost for 4138 attendances of 935 patients in 1905 was 6803·94 francs, or 1·64 francs per attendance; in 1906, for 5871 attendances of 1286 patients, the cost worked out at 9551·35 francs, or 1·85 francs per attendance. These figures include everything, not only drugs, gifts of food, and spittoons, but also the general working expenses of the department. This method of stating the cost is more trustworthy than that of reckoning the cost per patient, since only a certain number attend regularly; others come once only or very irregularly, not returning after receiving treatment which seems to have made them sufficiently well to return to work, whilst some others die. It is consequently impossible to make an accurate calculation on the basis of the number of patients treated.

A Spirochætal Disease Pathogenic to Man in Colombia.

At the Academy of Medicine on April 30th M. Blanchard described a recurrent febrile disease observed at Bogota at an altitude of 2800 metres; it resembled clinically the relapsing typhus fever of tropical Africa. It is not a fatal malady but clears up after three or four relapses. In the blood are found spirochætæ in very small numbers, resembling those found in the disease aforesaid. The specific nature of the disease is not yet determined, as inoculation of monkeys was not successful. It is not certain whether this parasite is to be identified with the spirochæta of relapsing fever or the spirochæta Duttoni of tick fever. In any case the disease, like the latter, is transmitted by an ornithodorus which attacks people in bed in the same way as the bed-bug. The existence of this disease at Bogota tends to prove the universal distribution of maladies due to spirochætæ throughout the tropical zone and also sheds further light on the pathogenic rôle of the ticks and large acarides of the genus Ixodes. It also explains the unpleasant experience of many travellers in different lands, especially in the north of Persia; in that country the Argas Persicus and Ornithodorus Tholozani cause amongst travellers a severe febrile infection of variable severity, which may be fatal, and which may be grouped amongst the spirochætal diseases; natives are not attacked on account of hereditary or acquired immunity. The disease reported from Colombia shows quite similar features.

The Influence of Vaccination on Whooping-cough.

At the Therapeutical Society on April 23rd M. Amat presented a study of this question. In his first case, an unvaccinated nursling suffering from whooping-cough, he found no good effect from vaccination, although six scars were obtained. Recently, however, M. Amat revaccinated two patients suffering from whooping-cough and they so notably improved that he has become very favourably inclined to this method of treating the disease.

Rectal Blennorrhagia and its Complications.

At the Academy of Medicine on April 30th Professor Fournier read a paper by Dr. Bronsurg-le-Bihan on this subject based on a comparatively large number of cases. In the first place, suppurative proctitis is not an obvious disease, as is often said; neither inflammation of the surrounding skin nor purulent discharge, as in gonorrhœa, is found; the pus is concealed and has to be looked for; it is of a brown colour and contains a rich bacterial flora. Three complications may be described—viz., acute periproctitis, which may lead to ischio-rectal abscess; chronic periproctitis, analogous to periurethritis; and rectal stenosis, which is generally mistaken for a syphilitic contracture.

Adulterated Flour.

A gross fraud carried out by dealers in flour in the South of France has recently been brought to light in the shape of the addition of talc to the flour to gain a greater profit. The excuse is given that the addition of talc increases the whiteness of the flour—a quality which the public demands even in the case of low-priced flours. The presence of talc, however, gives rise to various gastric troubles in those who partake of this adulterated flour. No fatal results have followed as yet, but a far-reaching inquiry is being undertaken into the matter. The practice seems to have attained considerable proportions among the flour dealers of Toulouse and of Poictiers.

The Operative Treatment of Cancer of the Stomach.

IN the *Korrespondenzblatt für Schweizer Aerzte* of May 1st Professor Kocher of Bern reports the results of 122 partial resections of the stomach followed by gastrostomy. He now performs very few palliative operations as the results proved unsatisfactory. In the 17 years from 1881 to 1898 he performed gastrostomy 52 times, Dr. Broquet reporting on these cases; in the next eight years there were 45 operations performed, the results of which Dr. Matti published; and Professor Kocher now adds 25 cases operated on during the last two and a half years. The mortality has decreased from 34·6 per cent. (Broquet) to 17·7 per cent. (Matti). Of the last 25 cases only four succumbed (16 per cent.). These four cases, however, had either been operated on previously or had severe complications. 19 simple and uncomplicated cases all recovered; this speaks well for the latest technique of operation. The importance of early diagnosis is obvious. The fate of such patients, says Professor Kocher, thus lies in the hands of the general practitioner. Where there is a suspicion of tumour in the gastric region a thorough examination under a general anæsthetic should be made. Inflation of the stomach should also be practised for diagnostic purposes and the contents of the stomach should be examined after a test meal. Sometimes it is desirable to apply the Glutzinsky method of emptying the stomach several times a day after meals. A decreasing amount of hydrochloric acid in the contents obtained points to the presence of cancer. Slight concealed hæmorrhages are of the greatest significance. Dr. Taworsky and Dr. Korolewicz recommended in a paper published in 1906 in the *Wiener Klinische Wochenschrift* (No. 38) that in all suspicious cases the fæces should be examined to see whether they contained blood. Dr. Boas of Berlin published a paper on the subject in 1905 (*Klinische Vorträge*). Hæmorrhages from a simple ulcer stop after a few days of rest in bed and careful dieting, but hæmorrhages due to cancer do not cease. Dr. Boas found blood in the stomach or fæces in 107 out of 124 cases of cancer of the stomach. Continuous decrease of appetite and increase of anæmia, together with symptoms of chronic gastritis without any persistent chronic irritation, as, for instance, from dietetic irregularities, gout, or the excessive use of alcohol, tea, tobacco, &c., are very suspicious. Lactic acid is only found in old-standing cases of ulcerating cancer with hyperacidity. Quite a number of publications on resection of the stomach for cancer have already appeared. Leriche (Lyon) collected 1366 cases operated on with a mortality of 25 per cent. Of Professor Kocher's 95 cases, all operated on at least three years ago, 13 are perfectly well and 18 died from other diseases without any return of cancer. The method of operation seems to be of importance as regards direct results. Guinard reports a mortality of 35·3 per cent. in 291 cases operated on by the Rhydygier-Billroth method. Professor Kocher has had a mortality of only 15·2 per cent. in 92 cases. He performs resection with consecutive gastro-duodenostomy and refers for the details of the operation to the latest edition of his book on operative surgery.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Serum Treatment of Diphtheria.

AN interesting paper on the value of anti-diphtheritic serum was read by Dr. Bittner at a recent meeting of the Brünner Medical Society. It was based upon observations made by him on 1515 children in the Children's Hospital. Of these 26 were taken into the hospital in a moribund condition and in 109 other cases the disease proved fatal, giving a mortality of a little over 7 per cent. It must be kept in mind that all these patients went to the hospital not on the first day of the disease but mostly on the third or fourth day and very often with grave complications. Surgical interference was necessary in 357 cases, including 249 intubations with a mortality of 14 per cent., 95 secondary tracheotomies with a mortality of 36 per cent., and 13 primary profession did not prevent him from pursuing medical studies. During his apprenticeship days he entered as a student at the Leeds School of Medicine, at that time and for long afterwards the most important provincial school in the country. He was dresser to the late Mr. Pridgin Teale, father of the present Mr. T. Pridgin Teale. Before the railway was opened he used to make the double journey from Dudley Hill to Leeds and back on foot. Five shillings a week indoors was the extent of his remuneration at the commencement of his apprenticeship and many of the duties about the surgery which are now considered menial formed part of his daily work. The amount of work which fell to the lot of the apprentice at that day was very great. To dispense for perhaps 100 patients a day, including the making of pills and powders by hand, keeping made up a large number of stock medicines ready for all eventualities, responding to urgent calls in the absence of the principal, and attending to the lion's share of some 300 midwifery cases a year, besides keeping the books, formed the daily and nightly routine of medical students. The only wonder is, how any time could be set apart for medical study. Professional examinations in those days, however, were directed to the discovery of whether candidates for qualification had practical knowledge of how things were done rather than into their knowledge of the more abstruse theories which might underlie practice. Even before he became qualified Mr. Lodge assisted his principal, then an old man, in a post-mortem examination which became classic, as it formed the starting-point of those investigations which, through the labours of the late Dr. J. H. Bell and others, have placed anthrax, or what was then called wool-sorters' disease, on the scientific basis where it now rests. Mr. Lodge wrote the account of the post-mortem examination of that case in the year 1854. In 1859 he took the diplomas of L.R.C.P. Edin. and M.R.C.S. Eng. He was a prompt, energetic, and self-reliant practitioner who was at all times ready to act as circumstances might require. The writer of this little memoir has himself entered a cottage home in company with Mr. Lodge and has seen him there and then cut down on a strangulated umbilical hernia, relieving the stricture by means of a pocket scalpel opening on the principle of a penknife. The patient made an excellent recovery without suppuration, although no special antiseptic precautions were taken. This was about the time when a distinguished student of a Scottish university was "sent back" by the Royal College of Surgeons of England, it was generally believed, because he had advocated in his examination more care for asepticism than was then considered necessary by the College authorities. So wide has been the change in medical opinion and in surgical practice. Some distinguished practitioners of medicine, if unknown to general fame—notably the late Mathew Lee, a very prompt, resourceful, and brilliant surgeon—were trained by Mr. Lodge. Although in some respects the present generation of medical practitioners is better educated than those who are rapidly passing away the older men in their time set a good example of courage, resource, probity, honour, and humanity. *Requiescant in pace.*

THE ROYAL SANITARY INSTITUTE: ANNUAL DINNER.

THE annual dinner of the Royal Sanitary Institute was held in the Langham Hotel, Portland-place, on Wednesday, May 15th, the Duke of Northumberland, the President of the Institute, occupying the chair. On the chairman's right were Major-General Right Hon. Lord Cheylesmore, Major-General Sir Thomas Fraser, Sir Lauder Brunton, Surgeon-General Sir Alfred H. Keogh, Sir John McFadyean, Surgeon-General A. M. Branfoot, Mr. S. Pollitzer, and Sir Alexander Binnie. To the left of the chair were Mr. H. D. Searles-Wood, Chairman of Council; Sir Francis Powell, Colonel Sir Charles M. Watson, Sir Aston Webb, Canon Barker, Sir James Crichton-Browne, Sir Thomas Brooke-Hitching, Sir Shirley F. Murphy, Dr. H. Gervis, Mayor of Brighton, and Dr. E. B. Forman.

After the usual loyal toasts had been proposed and honoured, Sir JOHN MCFADYEAN proposed the toast of "The Navy, the Army, and the Auxiliary Forces." He confessed to some amount of ignorance in regard to naval and military affairs, but expressed an admiration for both services. He thought that the Royal Army Medical Corps was in a high state of efficiency and it was a source of great satisfaction that it included a great many supporters of the institute. In reply to this toast Major-General Sir THOMAS FRASER referred to the importance of maintaining the strength of our forces on land and on sea.

The toast, "The Houses of Parliament," was proposed by Sir THOMAS BROOKE-HITCHING, who said that they owed much to Parliament in regard to sanitation. Major-General the Right Hon. Lord CHEYLESMORE replied for the House of Lords and Sir FRANCIS POWELL for the House of Commons. The latter paid great tribute to the zeal of Mr. John Burns in his efforts to secure sanitary conditions for the people. He was, he said, devoted heart and soul to the physical well-being and health of the people. He referred also to the attempts of the Government to insure a purer food supply. He thought that something had been gained when the public showed, though it might be incomplete, yet some knowledge of the laws of health. In conclusion he congratulated the Sanitary Institute on the excellent work which it was doing.

In proposing the toast of "The Royal Sanitary Institute" the Duke of NORTHUMBERLAND said that the progress of the institute was most satisfactory. The Secretary of State for War had recently complimented them on the standard of their examinations. The institute was in a sound financial position and he thought it a very excellent fact that they were spending their money in doing just that work for which the institute was established. Mr. SEARLES-WOOD, replying to this toast, gave some statistics as to the annual number of candidates examined on whom they looked as sanitary missionaries.

Sir ASTON WEBB, in proposing the toast of "The Visitors," said he should like to see legislative measures introduced providing for the regulation of the development of towns and cities, for open spaces, and for broad streets and avenues which would admit plenty of sunshine and air. Overcrowding was a terrible evil, engendering squalor and misery and a menace to the health of the bread-winner. Colonel Sir CHARLES WATSON replied and referred to the excellent work of the War Office in advancing sanitation.

The dinner was excellent and well served, and the organising committee and its secretary may be congratulated on the distinct success which attended the occasion.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—The Council of the Royal College of Surgeons of England on May 9th conferred diplomas of M.R.C.S. upon the undermentioned gentlemen who have completed the Final Examination in Medicine, Surgery, and Midwifery of the Examining Board in England, the Royal College of Physicians of London having conferred its licence upon the same candidates on April 25th last:—

George Henry Adam, King's College and St. Bartholomew's Hospital; Frederick Octavius Arnold, B.A. Cantab., Cambridge and Manchester Universities and St. Thomas's Hospital; Hugh Tuke Ashby, B.A. Cantab., Cambridge and Manchester Universities; Philip Heinrich Bahr, B.A. Cantab., Cambridge University and London Hospital; Harold Josiah Beddow, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Richard Charles Palmer Berryman, St. Bartholomew's Hospital; John Birch, Manchester University; Robert Edward Brayne, Guy's Hospital; Josiah Browne, King's College Hospital; Charles Walter Gordon Bryan, St. Mary's Hospital; Martin Binns Studer Button, L.S.A., London Hospital; Harry Vivian Bratt Bratt, B.A. Cantab., Cambridge University and London Hospital; William James Chapman, M.D., C.M., Toronto University and Middlesex Hospital; Percy John Chissell, Middlesex Hospital; Spencer Churchill, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Edward Bellis Clayton, B.A. Cantab., Cambridge University and King's College Hospital; Horace Charles Colyer, L.D.S., Charing Cross and University College Hospitals; Percival Sandys Connellan, University College, Bristol; Paul Alfred Creux, Lausanne University and London Hospital; Timothy Howell Davies, Middlesex Hospital; Arthur Hubert Treby Davis, St. George's Hospital; Herbert Edwin Tonge Dawes, B.A. Cantab., Cambridge University and St. Thomas's Hospital; George Denholm, M.B., B.S. Durh., Durham University; Arnold Thomas Densham, Cambridge University and Guy's Hospital; Horace Dimock, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Maurice Nason Dyde, Guy's Hospital; Howard Rollinson Elliott, Sheffield University; Carlton Atkinson Ellis, London Hospital; William Aiken Fairclough, M.B., Ch.B. New Zealand, New Zealand University; John Henry Farbstein, University College Hospital; Marmaduke Fawkes, St.

bleeding from her mouth and the stools were blood-stained. At the end of January her scalp suddenly became swollen, as did also her eyelids. In this condition she was taken to the surgical section of a hospital, where she was kept under observation until Feb. 12th. The diagnosis was hæmatoma capitis. The swelling diminished visibly after the application of wet compresses, so that at the time of her discharge from the hospital no tumour could be felt. On Feb. 25th she was again taken to the hospital. She then looked delicate and was very ill developed, but there were no characteristic signs of rachitis. The shafts of the left thigh-bone and the left tibia were enlarged and on palpation hard, irregular swellings could be felt. Over both parietal regions of the skull there was a swelling, through which, on deep pressure, the sparsely covered bone could be felt. Both the upper and the lower eyelids were generally of a bluish-red colour. From these symptoms the diagnosis of Barlow's disease was established. The following symptoms were especially characteristic: rapid development, pains in the limbs, subperiosteal hæmorrhages over the long bones and the bones of the skull, and hæmorrhages from the mouth and the bowel.

The Ears of School Children.

At a recent meeting of the medical society of a considerable country town in Hungary a school medical officer presented an interesting report on the examination of the ears of 1000 school children. The investigation was undertaken with the objects of ascertaining the amount of ear disease in children of the poorest class, and if necessary of drawing attention to the subject. For the purpose of this inspection ears were considered to be normal when the membranes presented the usual appearance and the whispered voice could be heard at a distance of from eight to 12 metres. Inability to pass this test with one or both ears was present in 634 out of 1000 children. Foreign bodies were found in the ears of 16 children, of whom 13 were girls. Of 107 cases of deafness there were adenoids in 91; 270 of the total number of children had a discharge from one or both ears and in 74 cases the discharge was suppurative. The number who had previously suffered from middle ear discharge was 219 and of these 183 had adenoids, and perforation existed in 49, while adenoids occurred in 416 children, of whom 387 presented some aural troubles.

A New Method of Percussion.

It is well known that among men similarly trained some are more expert than others in the use of percussion as a means of diagnosis. This shows that even in such a simple matter there is room for the exercise of skill. A common error in employing percussion is for the hand to be laid flat upon the surface to be examined; this has the effect of diminishing the resonance, and the proper method is to place only the extremity of the "anvil finger" on the surface to be examined. An improvement has been suggested by Dr. Janos Plesch, a Budapest practitioner. Instead of placing the hand on the surface in the manner just described he flexes the middle finger of the right hand at a right angle at the joint between the first and second phalanges, only the pulp of the finger being brought into contact with the surface, by forcibly extending the joint between the second and third phalanges. Percussion is then practised on the lower epiphysis of the first phalanx. This it is claimed gives a clearer resonance and has the advantage of enabling the observer to limit his investigation to a smaller area of the surface. In abdominal percussion this method is less disturbing to the patient than when the flat of the hand is applied to the surface.

May 13th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Appalling Mortality from Plague.

BESIDES the appalling mortality from plague there is little of medical interest to record. For the week ending April 13th 87,561 cases with 75,472 deaths were reported. This is an increase of some 14,000 cases and 12,000 deaths over the previous week. The Punjab heads the list with 45,296 cases and 39,084 deaths; then following are: United Provinces, 27,236 cases and 23,948 deaths; Bengal, 7915 cases and 7092 deaths; Bombay, 4092 cases and 2981 deaths; Central Provinces, 1218 deaths; and Rajputana, 348 deaths. Besides these weekly returns it is of interest to calculate the recorded mortality from the present epidemic of plague since its commencement. From October, 1896, to Dec. 31st, 1906, the total deaths reported have been 4,411,242, and during the first three months of the present year no less than 495,000 deaths have been known to occur. The mortality has fluctuated greatly:—

In 1901	there were	reported	274,000	deaths.
,, 1902	,,	,,	577,000	,,
,, 1903	,,	,,	851,000	,,
,, 1904	,,	,,	1,022,000	,,
,, 1905	,,	,,	951,000	,,
,, 1906	,,	,,	332,000	,,

With the intensely severe recrudescence which has occurred during the present year, especially in the north-west portion of India, even the highest of these figures may be exceeded. It will be noticed that the Bombay Presidency now takes a much better place than formerly and it would almost seem as if the disease were dying out gradually in that province. On the other hand, it must not be supposed that the official figures are accurate. The returns of plague in many places do not account for the whole of the increased mortality, and if that can be clearly shown for places where the registration of deaths is fairly correct it is reasonable to assume that plague carries off many more victims than the above figures show. In addition to plague there has been an increased mortality from all other causes. The death-rate for the whole of India has increased steadily during the past five years—viz., from 29 per 1000 in 1901 to 38 per 1000 in 1905 When it is found, however, that Madras recorded the low rate of 21·4 during 1905 one looks with suspicion upon the returns, notwithstanding that this province is practically free from plague. Amidst these unsatisfactory returns Calcutta takes a comparatively enviable position. The plague returns from this city, which has now been infected for over nine years, are very small compared with other places. It is true that over 50,000 people have died in the city, but this is a small number in all the circumstances. Last year there were only 2600 deaths and the recrudescence this year, though somewhat more severe than that of 1906, is less than half the severity of that of 1905. It has been noticed during the present outbreak that the average duration of each fatal case is about five days.

The Plague Department in Calcutta.

The question of the amalgamation of the plague department in Calcutta with that of the health department of the corporation is again up for discussion. Up to the present the plague department has been under the Bengal Government and has been worked smoothly and satisfactorily. Motives of economy occasionally sway the corporation and it is supposed that by taking over the subordinate staff of the plague department all the previous work of the two departments can be accomplished by the health department. The opportunity is being taken also of improving the status of the district health officers and of introducing new men. In the long run very little expense will be saved but if the new health officers and the new district officers are suitable men the transference of the plague department may be successful. It is the general opinion that the change if made with the existing staff would be disastrous.

April 26th.

Obituary.

SAMUEL LODGE, L.R.C.P. EDIN., M.R.C.S. ENG.

Mr. Samuel Lodge of Bradford, Yorkshire, died at his residence in that city on May 9th at the age of 83 years, during 25 of which he had held the position of police surgeon. He had been for a much longer time one of the poor-law medical officers and had been in receipt of a retiring allowance in that capacity for several years before his death. Mr. Lodge was the oldest medical practitioner in the city and with his departure the chief representative of what may be called the old school medical practitioner has disappeared. Sprung from substantial yeomen parents in Witney, Oxfordshire, and the eldest of a family of 11, all of whom predeceased him, he obtained the beginning of his medical education under the old system of apprenticeship as an articled pupil of Dr. W. Field. Before that time Mr. Lodge had been a schoolmaster, but the teaching profession did not prevent him from pursuing medical studies. During his apprenticeship days he entered as a student at the Leeds School of Medicine, at that time and for long afterwards the most important provincial school in the country. He was dresser to the late Mr. Pridgin Teale, father of the present Mr. T. Pridgin Teale. Before the railway was opened he used to make the double journey from Dudley Hill to Leeds and back on foot. Five shillings a week indoors was the extent of his remuneration at the commencement of his apprenticeship and many of the duties about the surgery which are now considered menial formed part of his daily work. The amount of work which fell to the lot of the apprentice at that day was very great. To dispense for perhaps 100 patients a day, including the making of pills and powders by hand, keeping made up a large number of stock medicines ready for all eventualities, responding to urgent calls in the absence of the principal, and attending to the lion's share of some 300 midwifery cases a year, besides keeping the books, formed the daily and nightly routine of medical students. The only wonder is, how any time could be set apart for medical study. Professional examinations in those days, however, were directed to the discovery of whether candidates for qualification had practical knowledge of how things were done rather than into their knowledge of the more abstruse theories which might underlie practice. Even before he became qualified Mr. Lodge assisted his principal, then an old man, in a post-mortem examination which became classic, as it formed the starting-point of those investigations which, through the labours of the late Dr. J. H. Bell and others, have placed anthrax, or what was then called wool-sorters' disease, on the scientific basis where it now rests. Mr. Lodge wrote the account of the *post-mortem* examination of that case in the year 1854. In 1859 he took the diplomas of L.R.C.P. Edin. and M.R.C.S. Eng. He was a prompt, energetic, and self-reliant practitioner who was at all times ready to act as circumstances might require. The writer of this little memoir has himself entered a cottage home in company with Mr. Lodge and has seen him there and then cut down on a strangulated umbilical hernia, relieving the stricture by means of a pocket scalpel opening on the principle of a penknife. The patient made an excellent recovery without suppuration, although no special antiseptic precautions were taken. This was about the time when a distinguished student of a Scottish university was "sent back" by the Royal College of Surgeons of England, it was generally believed, because he had advocated in his examination more care for asepticism than was then considered necessary by the College authorities. So wide has been the change in medical opinion and in surgical practice. Some distinguished practitioners of medicine, if unknown to general fame—notably the late Mathew Lee, a very prompt, resourceful, and brilliant surgeon—were trained by Mr. Lodge. Although in some respects the present generation of medical practitioners is better educated than those who are rapidly passing away the older men in their time set a good example of courage, resource, probity, honour, and humanity. *Requiescat in pace.*

THE ROYAL SANITARY INSTITUTE: ANNUAL DINNER.

THE annual dinner of the Royal Sanitary Institute was held in the Langham Hotel, Portland-place, on Wednesday, May 15th, the Duke of Northumberland, the President of the Institute, occupying the chair. On the chairman's right were Major-General Right Hon. Lord Cheylesmore, Major-General Sir Thomas Fraser, Sir Lauder Brunton, Surgeon-General Sir Alfred H. Keogh, Sir John McFadyean, Surgeon-General A. M. Branfoot, Mr. S. Pollitzer, and Sir Alexander Binnie. To the left of the chair were Mr. H. D. Searles-Wood, Chairman of Council; Sir Francis Powell, Colonel Sir Charles M. Watson, Sir Aston Webb, Canon Barker, Sir James Crichton-Browne, Sir Thomas Brooke-Hitching, Sir Shirley F. Murphy, Dr. H. Gervis, Mayor of Brighton, and Dr. E. B. Forman.

After the usual loyal toasts had been proposed and honoured, Sir JOHN MCFADYEAN proposed the toast of "The Navy, the Army, and the Auxiliary Forces." He confessed to some amount of ignorance in regard to naval and military affairs, but expressed an admiration for both services. He thought that the Royal Army Medical Corps was in a high state of efficiency and it was a source of great satisfaction that it included a great many supporters of the institute. In reply to this toast Major-General Sir THOMAS FRASER referred to the importance of maintaining the strength of our forces on land and on sea.

The toast, "The Houses of Parliament," was proposed by Sir THOMAS BROOKE-HITCHING, who said that they owed much to Parliament in regard to sanitation. Major-General the Right Hon. Lord CHEYLESMORE replied for the House of Lords and Sir FRANCIS POWELL for the House of Commons. The latter paid great tribute to the zeal of Mr. John Burns in his efforts to secure sanitary conditions for the people. He was, he said, devoted heart and soul to the physical well-being and health of the people. He referred also to the attempts of the Government to insure a purer food supply. He thought that something had been gained when the public showed, though it might be incomplete, yet some knowledge of the laws of health. In conclusion he congratulated the Sanitary Institute on the excellent work which it was doing.

In proposing the toast of "The Royal Sanitary Institute" the Duke of NORTHUMBERLAND said that the progress of the institute was most satisfactory. The Secretary of State for War had recently complimented them on the standard of their examinations. The Institute was in a sound financial position and he thought it a very excellent fact that they were spending their money in doing just that work for which the institute was established. Mr. SEARLES-WOOD, replying to this toast, gave some statistics as to the annual number of candidates examined on whom they looked as sanitary missionaries.

Sir ASTON WEBB, in proposing the toast of "The Visitors," said he should like to see legislative measures introduced providing for the regulation of the development of towns and cities, for open spaces, and for broad streets and avenues which would admit plenty of sunshine and air. Overcrowding was a terrible evil, engendering squalor and misery and a menace to the health of the bread-winner. Colonel Sir CHARLES WATSON replied and referred to the excellent work of the War Office in advancing sanitation.

The dinner was excellent and well served, and the organising committee and its secretary may be congratulated on the distinct success which attended the occasion.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—The Council of the Royal College of Surgeons of England on May 9th conferred diplomas of M.R.C.S. upon the undermentioned gentlemen who have completed the Final Examination in Medicine, Surgery, and Midwifery of the Examining Board in England, the Royal College of Physicians of London having conferred its licence upon the same candidates on April 25th last:—

George Henry Adam, King's College and St. Bartholomew's Hospital, Frederick Octavius Arnold, B.A. Cantab., Cambridge and Manchester Universities and St. Thomas's Hospital; Hugh Tuke Ashby, B.A. Cantab., Cambridge and Manchester Universities; Philip Heinrich Bahr, B.A. Cantab., Cambridge University and London Hospital; Harold Josiah Beddow, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Richard Charles Palmer Berryman, St. Bartholomew's Hospital; John Birch, Manchester University; Robert Edward Brayne, Guy's Hospital; Josiah Browne, King's College Hospital; Charles Walter Gordon Bryan, St. Mary's Hospital; Martin Binns Studer Burton, L.S.A., London Hospital; Harry Vivian Bratt Pratt, B.A. Cantab., Cambridge University and London Hospital; William James Chapman, M.D., C.M., Toronto University and Middlesex Hospital; Percy John Chisell, Middlesex Hospital; Spencer Churchill, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Edward Bellis Clayton, B.A. Cantab., Cambridge University and King's College Hospital; Horace Charles Colyer, L.D.S., Charing Cross and University College Hospitals; Percival Sandys Connellan, University College, Bristol; Paul Alfred Creux, Lausanne University and London Hospital; Timothy Howell Davies, Middlesex Hospital; Arthur Hubert Treby Davis, St. George's Hospital; Herbert Edwin Yonge Dawes, B.A. Cantab., Cambridge University and St. Thomas's Hospital; George Denholm, M.B., B.S. Durh., Durham University; Arnold Thomas Denham, Cambridge University and Guy's Hospital; Horace Dimock, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Maurice Mason Earle, Guy's Hospital; Howard Robinson Elliott, Sheffield University; Carlton Atkinson Ellis, London Hospital; William Aiken Fairclough, M.B., Ch.B. New Zealand, New Zealand University; John Henry Farbstein, University College Hospital; Marmaduke Fawkes, St.

Bartholomew's Hospital; Norman Flower, B.A. Oxon., Oxford University and Guy's Hospital; William Edward Lindsey Fowler, St. Bartholomew's Hospital; Claude Howard Stanley Frankau, St. George's Hospital; William Douglas Frew, L.D.S. Eng., Middlesex Hospital; Percy Charles Garrett, Manchester University; Harold Gibson, London Hospital; William Stonier Gibson, L.S.A., Middlesex and Manchester University; Alexander Savill Graham, Charing Cross Hospital; George Graham, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; William Robert Greening, Guy's Hospital; Frederic William Wandby Griffin, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Robert Eugene Vaughan Hale, B.A. Cantab., Cambridge and St. Andrews Universities, and St. George's Hospital; Hother McCormick Hanschell, St. Bartholomew's Hospital; Robert Norman Hartley, Manchester University; Lionel Chattock Hayes, Birmingham University; Arthur William Hayward, Cambridge University and Westminster Hospital; Charles Edward Kynaston Herapath, University College, Bristol; George Alexander Frederick Heyworth, B.A. Cantab., Cambridge University and London Hospital; Walter de Marchot Hill, St. Bartholomew's Hospital; Hendrik Houwink, London Hospital; Richard de Silva Illesinghe, L.M. & S. Ceylon, Ceylon Medical College and University College Hospital; Charles George Jarvis, M.D. Paris, Paris University; Richard Sydney Jenkins, Cambridge University and London Hospital; William Griffith Jones, L.D.S. Edin., Cardiff and Manchester University; Alexander John Kendrew, St. Bartholomew's Hospital; Solomon Krestin, M.D., B.Sc. Geneva University, University of Geneva; Malcolm Leckie, Guy's Hospital; Harold Howard Leeson, St. George's Hospital; William Samuel Leicester, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Richard Leonard Ley, B.A. Cantab., Cambridge University and St. Mary's Hospital; Conrad Loddiges, St. Bartholomew's Hospital; William Lovell, L.S.A., St. Mary's Hospital; Frederic Boulton Lowe, M.R.C.V.S., Guy's Hospital; James Barlow Macalpine, M.B., Ch.B. Man., Manchester University; Colin Francis Frederick McDowall, M.B., B.S. Durh., Durham University; Eric Lachlan Marchant, M.B., Ch.B. New Zealand, New Zealand University and London Hospital; William Beare Martin, Manchester University; John Harry Mayston, Guy's Hospital; Brian Bentley Metcalfe, Guy's Hospital; Henry Lewis Morgan, London Hospital; Edgar Lionel Robert Norton, Guy's Hospital; Henry Sandford Ollerhead, St. Mary's Hospital; Arthur O'Neill, St. Bartholomew's Hospital; Gerard Lyne Parsons, Westminster Hospital; Basil Thomas Parsons-Smith, St. Thomas's Hospital; Walter Patey, St. Thomas's Hospital; Stanley Paulin, M.B. Tor., Toronto University and London Hospital; Charles Arnold Pemberton, New Zealand University and Middlesex Hospital; Edward Campbell Pope, St. Mary's Hospital; Otto Carl Willy Prausnitz, M.D. Breslau, Breslau University; Geoffrey Price, St. Thomas's Hospital; John Lawson Rankine, Guy's Hospital; John Allister Renshaw, St. Bartholomew's Hospital; Kenneth Robinson, Manchester University; Cecil Frank Rumsey, L.D.S. Eng., Charing Cross Hospital and Cambridge University; Alfred Ludovicus Sachs, M.A. Cantab., Cambridge University and St. Thomas's Hospital; Leslie St. Vincent-Welch, St. Bartholomew's Hospital; John Selfe, St. George's Hospital; Edgar Arthur Shirvell, London Hospital; Arthur Leonard Singer, Cambridge University and London Hospital; William Fretson Skinner, L.S.A., Sheffield University and University College Hospital; Francis George Snoad, Birmingham University and St. Mary's Hospital; Edward Cyril Sparrow, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Lionel Duncan Stamp, Guy's Hospital; Frank Standish, London Hospital; George Stone, London Hospital; Arthur Arbuthnot Straton, St. Mary's Hospital; Joseph Roderick Sutherland, M.B., Ch.B. Glasg., Glasgow University; Ronald Ernest Todd, St. Thomas's Hospital; Sohrab Shapoorji Vazifdar, L.M. & S. Bombay, Bombay University; John Leeming Walker, M.D., C.M. McGill, McGill University, Montreal; Norman Hamilton Walker, St. Bartholomew's Hospital; Ronald Ralph Walker, B.A. Cantab., Cambridge University and Guy's Hospital; Harry Gordon Webb, St. George's Hospital; Henry Bright Weir, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Harrie Bruce Wickham, Liverpool University; Joseph William James Willcox, University College, Bristol; Cecil Lennox Williamson, Liverpool University; and Lorton Alexander Wilson, Manchester University.

The Royal College of Physicians also conferred its licence upon the following gentlemen who have already received their M.R.C.S. diploma:—

Robert Dixon Brown, St. Thomas's Hospital; Henry Orton Howitt, McGill University; Charles Grange McGreer, Queen's University, Kingston, and Middlesex Hospital; and Charles Edward Waldron, London Hospital.

Royal College of Surgeons of England.—At the half-yearly Primary Examination for the Fellowship of the above College, held on May 2nd, 3rd, 7th, 8th, 9th, and 10th, 113 candidates presented themselves for examination, of whom 33 per cent. were approved and 66 per cent. were rejected. The following are the names of the successful candidates:—

George Cuthbert Adeney, M.B., B.S. Lond., M.R.C.S., L.R.C.P. St. Thomas's Hospital; William Appleyard, M.B., B.S. Lond., M.R.C.S., L.R.C.P., University College Hospital; Arthur Laurence Candler, St. Bartholomew's Hospital; Hubert Chitty, M.B., B.S. Lond., M.R.C.S., L.R.C.P., University College Hospital; George Herbert Colt, M.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and St. Bartholomew's Hospital; Percival Templeton Crymble, M.B., B.Ch., B.A.O. R.U.I., Queen's College, Belfast; Edmund Arthur Dorrell, M.R.C.S., L.R.C.P., D.P.H., University College, Bristol, and St. Bartholomew's Hospital; Augustin Pownall Fry, St. Bartholomew's Hospital; Wilfred Watkinson Holtzmann, M.A., M.B., B.C. Cantab., London Hospital; Charles William Menelaus Hope, M.B., B.S. Lond., M.R.C.S., L.R.C.P., King's College; William Johnson, Guy's Hospital; John Lawrence Johnston, Guy's Hospital; Hugh Braund Kent, Guy's Hospital; Alexander Kinder, M.B., B.Ch., B.Sc. New Zealand, M.R.C.S., L.R.C.P., New Zealand University and London Hospital; John Christopher Lyth, Leeds University; John Alexander McCollum, M.B. Toronto, M.R.C.S., L.R.C.P., Toronto University and King's College; Michael McCann, M.B., B.Ch. R.U.I., King's College and Queen's College, Belfast; Francis Edmund McKenty, M.D., C.M. McGill, M.R.C.S., L.R.C.P., McGill University; Reginald Hawksworth Mawhood, B.A. Cantab., St. Bartholomew's Hospital; Richard Drummond Maxwell, M.D. Lond., M.R.C.S., L.R.C.P., London Hospital; Edwin Bertram Morley, London Hospital; Krishna Moreshwar Pardhy, M.R.C.S., L.R.C.P., King's College and Birmingham University; George Henry Pooley, F.R.C.S. Edin., Cambridge University and St. George's Hospital; John Wardell Power, M.B., C.M., Sydney University; Frederick Charles Pybus, M.B., B.S. Durh., Durham University; Paul Bernard Roth, M.B., Ch.B. Aberd., Aberdeen University and London Hospital; Henry Charles Gustavus Semon, M.A., M.B., B.Ch. Oxon., M.R.C.S., L.R.C.P., Oxford University, University College and King's College; George Charles Edward Simpson, B.A., M.B., B.C. Cantab., B.Sc. Lond., Cambridge University and St. Bartholomew's Hospital; Henry Sessions Souttar, M.A., M.B., B.Ch. Oxon., M.R.C.S., L.R.C.P., Oxford University and London Hospital; Joseph Collingwood Stewart, M.B., M.S. Durh., Durham University and King's College; Eward Philip Stibbe, Charing Cross Hospital; Harvey Sutton, M.D., Ch.B. Melb., Melbourne University and Oxford University; Harold Lindley Tasker, University College; Henry Ashbourne Treadgold, B.A. Cantab., Cambridge University; Wilfrid Warwick Treves, B.A. Cantab., Cambridge University and London Hospital; Cranston Walker, Birmingham University; and George Ewart Wilson, M.B. Toronto, Toronto University and London Hospital.

University of Edinburgh.—The following is the official list of passes at the recent professional examinations for degrees in Medicine and Surgery:—

First Professional Examination.—J. A. Andrews, P. W. Bedford, B. J. W. Bennetts, Prem Nath Berry, Charlotte M. Birnie, J. R. Boyd, U. F. F. Brown, C. E. H. Browne, H. M. Buchanan, F. D. Cairns (with distinction), E. H. Cameron, William Campbell (with distinction), E. R. Carlos, Tapeshurnath Caul, Anna Chase, G. J. Cillie, Andrew Cochrane, Lilian Cook, D. H. D. Cran, May F. F. Davidson, Robert Dow, W. E. Fitzgerald, H. H. C. Fuller, Alexander Galletly, K. A. Gilchrist, J. P. Glyn, C. W. Graham, A. C. Heard, Jack Hewat, Samuel Hodkinson, N. J. Hofmeyr, B.A., John Honeyford, J. L. Huggan, W. H. Irving, Abraham Jasinowsky, H. A. Khin, Archibald Langwill, J. J. Levin, Thomas Lindsay, R. B. Llewellyn, F. M. Low, Eva M. Lyon, E. F. G. M'Auliffe, G. N. M'Diarmid (with distinction), E. C. Mackay, Robert M'Laren, N. G. M'Lean, Peter M'Nab (with distinction), D. F. Macrae, W. C. B. Meyer, Lucy M. Muir, F. D. Pascoe, L. T. Poole, S. H. Pugh, K. Ahobala Rao, A. B. Robertson, W. H. Robinson, H. A. Von Ronn, C. M. Rout, E. St. J. Scally, T. M. Sellar, Robert G. Shaw, S. F. Silberbauer, W. F. W. Sim, W. D. D. Small, B. H. H. Spence, H. H. Stewart, R. M. Stewart, James Taylor, J. H. Tennent, C. M. R. Thatcher, P. H. du Toit, F. L. Tulloch, Mary B. Walker, S. J. A. Hall Walsh, F. H. C. Watson, John Watson, J. H. Watson, T. C. Welsh, L. S. Willox, and N. C. Young.

Second Professional Examination.—D. C. Adam, T. A. Adams, David Aiken, R. J. Allsopp, Alexander Archibald, Alice E. M. Babington, T. H. Balfour, Eveline R. Benjamin, W. M. Biden, T. C. Borthwick, F. A. J. Brodziak, G. S. Brown, A. Ninian Bruce, B.Sc., W. F. Buist, W. L. Burgess (with distinction), B. N. Burjorjee, A. W. Burton (with distinction), Sarah E. Boyers, J. A. Campbell (with distinction), Louis Cassidy, John Cathcart, G. L. Cawkwell, R. B. Chamberlain, P. H. Chauvin, B. R. Chopra, F. M. Chrystal, N. A. Coward, James Crocket, Lucy E. Davies, J. K. M. Dickie, Adelaide A. Dreaper, J. W. C. Drever, F. A. Duffield, A. M. Elliott (with distinction), W. C. Fragoso, E. L. Galletly, Cromwell Gamble, Mary M. Gardner, G. H. Garnett, A. W. Gill, T. J. Gilmore, D. M'D. Grant, R. D. Latimer Greene, S. C. Sen Gupta, A. G. Hamilton, E. S. B. Hamilton, H. F. Hamilton, R. C. Harkness (with distinction), J. B. Haycraft, John Henderson, G. R. Inglis, Flora Innes, W. C. Jardine, A. M. Jones, G. E. King (with distinction), J. H. Lawry, D. O. Lee, L. A. Lewis, Harry Lipetz, W. R. Logan, H. A. V. Loots, C. L. Low, Mary Low, M.A., H. F. Lumsden, Alexandra B. MacCallum, David M'Carrol, A. J. M'Connell, William Macdonald, G. H. G. Mackay, John Cosserat Mackenzie, Duncan Mackinnon, A. G. MacLeod, Donald M'Phail, R. C. MacQueen, John Malloch, T. H. B. Mathewson, W. M. Menzies, William Messer, E. L. Middleton, L. M. V. Mitchell, John Montgomery, S. P. Moore, J. A. Mortimer, J. M. Moyes, C. C. Murray, Kishanlal Nehru, J. G. Nicholson, M.A., F. H. Noronha, James Oag, M.A., J. B. T. Oxley, J. J. Pace, S. P. P. Proctor, John Renwick, D. G. Robertson (with distinction), W. S. Robertson, D. M. Thomson (with distinction), R. W. Lang Todd, B.Sc., Raymond Verel (with distinction), F. H. de Villiers, A. A. Walbrugh, E. A. Walker, W. Oliphant Walker, H. S. Wallace, L. E. B. Ward, John Ware, F. K. te Water, F. W. Waterworth (with distinction), A. Pirie Watson, M.A., H. Ballingall Watson, M.A., H. L. Watson Wemyss, Adam White, D. J. Williamson, E. D. Wilmot, G. G. Wray, A. G. Yates, M.A., and W. A. Young.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Hermann Schröder of Greifswald has been appointed Extraordinary Professor of Odontology.—*Halle:* Dr. Ernst Adolf Schmidt of Dresden, formerly of Bonn, has been appointed Professor of Medicine.—*Kiel:* Dr. Ernst W. Baum has been recognised as *privat-docent* of Surgery.—*Pavia:* Dr. Francesco Turpura has been recognised as *privat-docent* of External Pathology.—*Pisa:* Dr. Ferdinando Fontana has been recognised as *privat-docent* of Operative Medicine.—*Prague (German University):* Dr. A. Elschnig of Vienna has been appointed Professor of Ophthalmology, in succession to the late Dr. Czermak. Two new professorships of Laryngology and Experimental Morphology are about to be established.—*Strasburg:* Dr. Wilhelm Schumburg has been recognised as *privat-docent* of Hygiene.—*Turin:* Dr. Giuseppe Vicarelli has been appointed Extraordinary Professor of Midwifery.—*Vienna:* Dr. O. Löwi, *privat-docent* of Pharmacology, and Dr. O. von Fürth, *privat-docent* of Medical Chemistry, have been promoted to Extraordinary Professorships.

LONDON TEMPERANCE HOSPITAL.—On Tuesday, May 14th, the new out-patient hall of this hospital was formally opened by H.R.H. Princess Louise, Duchess of Argyll, in the presence of a large number of supporters of the institution. An out-patient department has been in active operation since the establishment of the hospital in 1873 and during last year 25,216 persons were treated as out-patients, but the buildings formerly used for this purpose had long been recognised as unsuitable and inadequate, and the council of King Edward's Hospital Fund for London initiated the new scheme and made generous contributions towards the cost which has amounted to £11,000, but of this sum £3,800 have yet to be raised before the structure is fully paid for. The new building has waiting-room accommodation for 200 patients and possesses convenient consulting rooms, operating theatre, dispensary, and other advantages. It has been erected according to the designs of Mr. Rowland Plumbe, F.R I.B.A. The board pleads for numerous and liberal remittances to meet the financial liability and to leave the new work unhampered in this respect.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the President, Vice-President, and Council held on May 7th the following examiners were elected for the ensuing year. Court "A," for Conjoint Licence, Diploma in Public Health, and Preliminary. Anatomy: Mr. Alexander Fraser and Dr. Bertram C. A. Windle. Surgery: Mr. Charles A. K. Ball, Mr. Alexander Blaney, Mr. F. Conway-Dwyer, and Mr. G. Jameson Johnston. Physiology and Histology: Dr. Denis J. Coffey and Mr. E. L'Estrange Ledwich. Pathology and Bacteriology: Mr. Arthur Hamilton White. Midwifery and Gynæcology: Mr. Frederick W. Kidd. Biology: Mr. John J. Burgess. Ophthalmology: Mr. Arthur H. Benson and Mr. Patrick W. Maxwell. Sanitary Law and Vital Statistics: Mr. Edward Francis Stephenson. Engineering and Architecture: Mr. Caleb J. Powell. Languages: Mr. L. J. Woodroffe. Mathematics, Physics, Dictation, and English Essay: Mr. J. W. Tristram. Dutch: Mr. John C. Pretorius. Court "B," for Fellowship, Licence in Surgery (for registered practitioners), Licence in Midwifery (for registered practitioners), and Licence in Dental Surgery. Anatomy: Mr. Patrick Joseph Fagan and Mr. Alexander Fraser. Surgery: Mr. Alexander Blaney, Mr. F. Conway-Dwyer, Mr. G. Jameson Johnston, and Mr. Richard Lane Joynt. Physiology and Histology: Dr. Denis J. Coffey and Mr. E. L'Estrange Ledwich. Pathology and Bacteriology: Dr. Arthur E. Moore and Mr. Arthur Hamilton White. Midwifery and Gynæcology: Mr. Frederick W. Kidd. Chemistry and Physics: Mr. Edwin Lapper and Mr. Robert J. Montgomery. Dental Surgery and Pathology: Mr. George M. P. Murray and Mr. William G. Story. Mechanical Dentistry: Mr. Daniel L. Rogers and Mr. Thomas F. Studley.

UNIVERSITY OF OXFORD.—In a Congregation held on May 7th the forms of statutes establishing a professorship in human anatomy and a professorship in pathology were promulgated and the preambles thereof approved (*nemine contradicente*).—The Board of the Faculty of Medicine will in and after Trinity Term, 1908, require from candidates for the Final B.M. examination, in addition to the certificates already required, a certificate showing attendance on a course of practical instruction in the administration of anæsthetics in a hospital approved by the Board.

LITERARY INTELLIGENCE.—"Crutches to Help Cripple Children" is a publication to be issued by Messrs. Bemrose and Sons on June 5th on behalf of the Lord Mayor's Cripples' Fund, and Sir William Treloar's charitable work ought to be assisted by considerable sales. Sir Douglas Straight is acting as editor of the literary section and Sir James D. Linton is responsible for the art section, each, of course, giving his services. Many well-known authors and artists have made gratuitous contributions, so that the result bids fair to be a literary and artistic success. The entire profits on the book are to be devoted to the fund now being raised by the Lord Mayor for the provision of homes to treat the tuberculous cripples of the poor, for which purpose a sum of £60,000 is required.

UNIVERSITY OF CAMBRIDGE.—Professor Nuttall will deliver his inaugural lecture in the anatomy theatre on May 22nd at 4.30 P.M.—The syndicate appointed for the purpose has submitted plans for a large extension of the chemical laboratory adjoining the new medical school. The cost is estimated at £13,500. The number of students in attendance at the beginning of the academical year was 384, and the pressure on the accommodation of the laboratory is very great.—The matriculations during the present term have brought the entry of freshmen for the year up to 1083, which is the largest on record.—The honorary degree of D.Sc. is to be conferred on Sir Thomas Fraser, F.R.S., professor of materia medica in the University of Edinburgh.—Mr. W. Bateson, F.R.S., St. John's, is again appointed deputy for the professor of zoology and comparative anatomy.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The annual general meeting of this society was held on May 9th, Dr. G. F. Blandford, the President, being in the chair. 14 members were present. One vice-president and six directors were elected to fill the vacancies in the court. A cordial vote of thanks was passed to the editors of the medical journals for their courtesy in publishing the reports of the meetings of the society and endeavouring to make it better known to the members of the medical profession. The report for 1906 was adopted, and the following is a brief *résumé* of the work done by the society during the past year. The invested funds of the society amount to £98,960, from which is derived in interest the sum of £3114 4*s.* 11*d.*; £334 19*s.* were received in subscriptions and donations. The working expenses for the year were £217 10*s.* 5*d.* Amongst the annuitants of the charity—namely, 54 widows and 21 orphans—the sum of £3268 10*s.* was distributed, each widow receiving on an average £50 and £10 extra at Christmas and each orphan £10 and £3 extra at Christmas. During the year six widows who were in receipt of grants died. One, whose husband had paid a life subscription fee of £21, received £900. Five widows were elected during the year and on Dec. 31st there were 47 widows and 20 orphans in receipt of grants. One of the widows has been on the books since 1854 and has already received over £2000. Relief is only granted to the widows and orphans of deceased members who have paid their annual subscription for three years or are life members. During the year nearly 50 letters were received from widows of medical men who, in many instances, had been left practically penniless, asking for relief, but this had to be refused as their husbands had not been members of the society. The directors feel that they cannot too strongly urge upon the members of the medical profession, especially the younger ones, the desirability of joining the society. Particulars and application forms may be obtained from the secretary at the offices of the society, 11, Chandos-street, Cavendish-square, W.

Asylum Workers' Association.—The annual general meeting of this society (founded in 1895 to improve the status of asylum nurses and attendants, to provide for them "homes of rest and nursing," and to enlist public sympathy in their work) will be held at the Medical Society's house, 11, Chandos-street, Cavendish-square, W., on Wednesday, May 29th, at 4 P.M., Sir William J. Collins presiding. The Bishop of Croydon, Sir John Batty Tuke, Sir J. Crichton-Browne, Dr. Robert Jones (President of the Medico-Psychological Association), Dr. G. H. Savage, and some of the Commissioners in Lunacy, have intimated their hope to be present. There will be a presentation of two gold and two silver medals, awarded by the association for long and meritorious nursing service. All interested in asylum work and workers are cordially invited to attend.

Post-Graduate Classes at Trinity College, Dublin.—From the announcement of these classes which appears in our advertising columns it will be seen that this year the course will begin on June 17th and will terminate on July 6th. Trinity College was the first Irish medical school to inaugurate a special course of instruction for medical practitioners. The arrangements of the classes this year are on lines similar to those which proved so successful in past years. The earlier part of each day is devoted to hospital work, while the afternoons are spent at clinical pathology, operations, x ray work, and the like. From a social point of view one of the attractive features of the Trinity course is the possibility of residing in College rooms and of dining on commons. As the number of rooms available is limited early application by those desirous of living in College is necessary. All the advantages and privileges of the course are open to qualified medical practitioners. The honorary secretary, Dr. A. R. Parsons, 27, Lower Fitzwilliam-street, Dublin, will be pleased to give any further information that may be desired.

The Society of Arts.—At a meeting of the Society of Arts, held on May 8th, Mr. Paul Schlicht read a paper on the Production of Coke and its Application in Domestic Fires. His chief object was to recommend the adoption in London of the American practice by which ordinary bituminous coal before being used as fuel was treated in a "by-product coke oven." With this apparatus coke of several different kinds could be obtained at will, including either a dense hard coke free from volatile matter and suitable for metallurgical purposes or a porous coke containing a certain amount of volatile matter which enabled it to burn brightly in a domestice fire-place. Coke was introduced about the year 1620, the primitive process of manufacture, which required from five to eight days, being the ignition of coal in mounds. The coking period in the modern regenerative oven has been reduced to 24 hours for metallurgical coke and to 18 hours for domestic and industrial cokes which did not require the complete expulsion of the volatile portions of the coal but were in fact preferable therewith on account of their flame-producing properties, greater porosity, and greater ease of ignition. Mr. Schlicht said that when a ton of raw coal was coked in a modern by-product oven, there were obtained about 14 hundredweight of coke suitable for domestic and metallurgical purposes, 100 pounds of coal-tar containing a great number of valuable constituents, and 5000 cubic feet of gas suitable for illumination, for heating, and as a source of power in gas engines. The gas used for lighting purposes in Boston, Baltimore, and some other American cities was now made almost entirely in by-product ovens. The coke made in these ovens was much superior to that obtained in the older processes of gas manufacture, being less porous than the latter and more uniform. After referring to the methods suggested by Sir William Siemens and Sir Charles Cookson for burning ordinary porous coke or anthracite in combination with gas Mr. Schlicht said that he had invented a method by which both an up-draught and a down-draught could be maintained in the same chimney, the former being in the centre and the latter next the sides. In a closed stove provided with such a chimney a coke or anthracite fire could be made to burn brightly for 26 hours. Several diagrams illustrating this invention were shown on the screen and also two photographs taken from the roof of the South-Eastern Railway Station in Cannon-street, E.C., showing that the atmosphere of London was comparatively pure in the early morning before the domestic fires were lighted for the day. In the subsequent discussion Dr. H. A. Des Vœux, speaking as a member of the Coal Smoke Abatement Society, expressed a fear that the prejudices of the population and their disinclination to accept new ideas would be a barrier to the use of coke in domestic fire-places. He related instances of this from his own experience as well as from that of Sir Charles Cookson. Dr. Owens also described some of the work done by the Coal Smoke Abatement Society.

The Proposed Union of London Provident Dispensaries.—On May 9th a conference of representatives of the provident dispensaries of London was held at 42, Grosvenor-gardens, the residence of Mr. Francis Buxton, who presided. The chief object of the conference was the discussion of plans for closer coöperation between provident dispensaries and to consider their relationship to the medical profession, the hospitals, and the three chief hospital funds. The following resolution was adopted :—

> That coöperation between all the provident dispensaries of London is desirable, whereby their aims and work may be advanced, reciprocal action between them and hospitals be promoted, and the transference of members from one dispensary to another be made more general.

A provisional committee, consisting of Sir William Bousfield, Mr. Francis Buxton, Sir Edward Brabrook, Mr. Carlton Lambert, Colonel Montefiore, Mr. H. J. Powell, and Dr. W. Winslow Hall, was elected to carry out the objects of the resolution and to arrange for the appointment of a consultative council representative of all the provident dispensaries in London.

Royal College of Physicians of Edinburgh.—A quarterly meeting of the Royal College of Physicians of Edinburgh was held on May 7th, Dr. C. E. Underhill, the President, being in the chair. The Registrar reported that since the last quarterly meeting 41 persons had obtained the Licence of the College by examination. Sir John Batty Tuke was unanimously re-elected representative of the College on the General Medical Council for a period of five years from May 7th, 1907. Dr. John Playfair was re-elected as representative of the College on the conjoint committee of management of the triple qualification. It was intimated that Dr. Lewis C. Bruce had been appointed Morison Lecturer for the ensuing session. Dr. Harry Rainy was recognised as a lecturer on Practice of Physic. The Freeland-Barbour Fellowship was awarded to Mr. Ninian Bruce, B.Sc. By vote of the College, Edmund McDonnell, a Licentiate of the College, was expelled from the College and deprived of his licence to practise, as granted by the College, and of all his rights and privileges as Licentiate.

Westminster Hospital Festival Dinner.—At the festival dinner in aid of the funds of Westminster Hospital held on May 10th in the hall of the Inner Temple, under the presidency of the Lord Chancellor, and at which Sir Henry Campbell-Bannerman and a large and distinguished company were present, Sir John Wolfe Barry, who responded to the toast of "Prosperity to Westminster Hospital," said that with the utmost economy the expenditure of the charity could not be kept below £19,000 per annum. The hospital had an income of £3000 per annum from house property, received £6000 per annum from the three hospital funds, and the annual subscription amounted to only £1500. If the hospitals of London could not be run upon voluntary charity but were put under the administration of local authorities they would lose the highest skill in the medical and surgical world which they now commanded. The medical profession, he believed, would not give their services to rate-aided institutions in the same way that they now did to hospitals supported by voluntary contributions. During the evening subscriptions to the amount of £6500 were announced and it was stated that two gentlemen had promised to give £1000 each if three others would make a similar offer within the next six months.

BOOKS, ETC., RECEIVED.

Baillière, Tindall, and Cox, 8, Henrietta-street, Covent Garden, London, W.C.

A Synopsis of the British Pharmacopœia (1898). By H. Wippell Gadd, F.C.S., Lecturer on Pharmacy at the University College, Exeter; Director of the Laboratories of Evans, Gadd, and Co., Limited. Sixth edition, containing a Synopsis of the Poison Laws of Great Britain and Ireland. Price 1s. net.

FROWDE, HENRY, Oxford University Press, London, New York, and Toronto.

LONGMANS, GREEN, AND CO., 39, Paternoster-row, London, E.C. (CHARITY ORGANISATION SOCIETY, Denison House, Vauxhall Bridge-road, London, S.W.)

The Annual Charities Register and Digest, 1907. Sixteenth edition. By C. S. Loch, Secretary to the Council of the Charity Organisation Society, London. Price 5s. net.

Royal University of Ireland. The Calendar for the Year 1907. *Price not stated.*

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Notification of Births Bill.

THE Notification of Births Bill, which Lord ROBERT CECIL introduced into the House of Commons to deal in some measure with the problem of infantile mortality, has been read a second time. It was allowed to go through unopposed. Under the new rules of procedure it is automatically referred to a standing committee.

The Vaccination Acts.

The Personal Rights Association has petitioned the *House of Commons* to repeal the Vaccination Acts.

Accidents at Mines and Quarries.

The general report and statistics for 1906 on mines and quarries show the number of accidents occurring in them. *It has just been* laid on the table of the House of Commons and will be issued as a Parliamentary paper in due course.

Experiments on Living Animals.

Mr. HERBERT SAMUEL, the Under Secretary of State for the Home Department, on May 8th moved in the House of Commons for a return showing the number of experiments *on living* animals during the year 1906 under licences granted under the Act 39 & 40 Vict., and distinguishing *the nature of* the experiments. The return was granted.

The Vaccination Bill.

Sir JOHN BATTY TUKE has *given notice that he* will move the rejection of the Vaccination Bill after the motion for its second *reading is* made.

The Rejection of Aliens.

One of the tables appended to the first annual report on the Aliens Act, 1905, shows that during the year 1906 leave to land was withheld by the immigration officer in 232 cases on medical grounds. In 161 of these cases appeals were lodged, and of them 69 were successful, whilst 92 failed. The total number of *rejections* on the ground of want of means as well as on medical grounds was 493. This total is reached after the successful appeals against the decision of the immigration officers have been eliminated. In the case of transmigrants who were proceeding to destinations beyond the United Kingdom 1432 persons were *rejected*. 1419 of these *rejections* were on medical grounds and seven on the ground of insanity.

The Royal Commission on Vivisection.

The minutes of evidence *taken before the Royal Commission on* Vivisection during February and March, 1907, are published in the form of a Parliamentary Blue-book. Amongst the witnesses whose evidence is recorded in it are Mr. W. H. POWER, principal medical officer to the Local Government Board; Professor A. R. CUSHNY, University College, London, who represented the committee of medical and scientific societies; Miss A. KENEALY, representing the Parliamentary Association for the Abolition of Vivisection; Lord RAYLEIGH, President of the Royal Society; Sir R. DOUGLAS POWELL, President of the Royal College of Physicians; and Dr. FREDERICK TAYLOR, senior physician to Guy's Hospital.

HOUSE OF COMMONS.

WEDNESDAY, MAY 8TH.

Vaccination Fees.

Sir WILLIAM BULL asked the President of the Local Government Board what provision he proposed to make for the compensation of the vaccination officers who would lose the greater part of their fees if his Bill passed into law.—Mr. JOHN BURNS furnished the following written reply: I *do not* propose to make provision on this subject in the Bill.

Butter and Margarine Bill.

On the resumed debate on the motion for the second reading *of* the Butter and Margarine Bill,

Mr. ASHLEY expressed the hope that some provision would be inserted in the Bill whereby it would be made compulsory to label butter substitutes with a name in which the word "butter" did not occur, so that consumers should be in no doubt as to what they were getting.

Lord WILLOUGHBY DE ERESBY, in *supporting* the Bill, *said that it* was desired by agriculturists throughout the country. He hoped steps would be taken to prevent butter substitutes being *sold which* contained as much as 24 per cent. of moisture.

Mr. CROSS observed that to permit *butter substitutes to be sold* containing 24 per cent. of moisture would be a dangerous thing for the public and would subject *farmers* to an *unfair competition*. There might be many circumstances in which butter substitutes might be sold to an unguarded *public*. *He had received* communications from many farmers' associations in Scotland drawing attention to this provision *in the Bill and taking exception to it*.

The Bill was then read a second time.

THURSDAY, MAY 9TH.

The Board of Education and a Medical Department.

Mr. RAMSAY MACDONALD asked the *President of the Board of Education* whether he proposed to create a medical department in connexion with the Board of Education so as to supervise and coördinate local work done in connexion with the medical inspection of school children; and whether, in order to create such a department, legislation was necessary.

Mr. WEDGWOOD also asked the President of the Board of Education whether, *in view* of the fact that it was not competent *for a private Member to move* in committee on the Education (Administrative *Provisions*) Bill for the establishment of a permanent medical department at the Board of Education, he could say now what medical machinery the Board intended to adopt to carry out the proposals of the *Bill*; and, if he could not give this information, whether he would say on the advice of what experts *or* reports he intended to act.—Mr. MCKENNA said in reply to *both* questions: I regret I cannot add anything to an *answer* which I have already given to the effect that it would be premature to decide what machinery will be required by the Board of Education on the Education (Administrative Provisions) Bill becoming law; but *my honourable* friends may rest assured that I am *fully* alive to the importance of this question. The staff of the Board of Education can be increased with the consent of the Treasury *without legislation*. I may add that the Board's staff already includes two medical men.

MONDAY, MAY 13TH.

Vaccination and Education.

Mr. BOWLES asked *the First* Lord of the Treasury whether he would consider the desirability of introducing legislation to assimilate the practice with regard *to compulsory State education to that now* existing in the case of compulsory State vaccination, under which a conscientious objection *or* one fine *absolved the* parent from the consequences of not complying with the statute.—Mr. ASQUITH (on behalf of Sir Henry Campbell-Bannerman) *replied*: *I do* not see any connexion in principle between the two matters referred to.

The Prevention of Tuberculosis.

Sir FRANCIS CHANNING asked the *President of the* Local Government Board whether he had *considered* the resolutions passed at the meeting of the National Association for the Prevention of Consumption and other Forms of Tuberculosis urging immediate action in Parliament in pursuance of the recommendations in the recent report of the Royal Commission on Tuberculosis; and whether he was now able to state what steps would be taken *to give effect* to those recommendations.—Mr. JOHN BURNS said in reply: I am aware that resolutions have been passed at the meeting referred to, but I have not at present received *copies* of them. The recommendations of the Royal Commission relate to *matters* of much moment, and I am not at present in a position to make any definite statement with regard to the action which should be taken in consequence *of them*. They are, however, receiving my consideration.

The Royal College of Surgeons of England.

Sir WILLIAM COLLINS asked the *Prime Minister* whether he had *now* considered the *memorial presented* to him last session on behalf of the Members of the Royal College of Surgeons of England, asking him to take such steps as might secure to Members some voice in the management of the College and its *property*; whether any representations had been made by the Privy Council to the College of Surgeons and with what result; and whether he would lay upon the table of the House copies of any communications which had passed.—Sir HENRY

ROYAL EAR HOSPITAL, Dean street, Soho, W.—House Surgeon for six months. Salary at rate of £40 per annum.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Assistant to the Clinical Pathologist and Assistant Anæsthetists (females).

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, S.E.—Junior Resident Medical Officer. Salary at rate of £40 per annum, with board and washing.

ST. BARTHOLOMEW'S HOSPITAL.—Lectureship in Anatomy.

ST. GILES, CAMBERWELL, WORKHOUSE, East Dulwich.—Locum Tenens for Medical Officer for four weeks. Salary at rate of 4 guineas per week, with board, lodging, and washing.

ST. MARY'S HOSPITAL, Paddington, W.—Dental Surgeon. Also Resident Casualty House Surgeon. Salary £100 per annum, with board and lodging.

ST. THOMAS'S HOSPITAL.—Assistant Physician.

SELBY, LEEDS TUBERCULOSIS ASSOCIATION SANATORIUM, Gateforth.—Resident Medical Officer for six months. Salary at rate of £100 per annum, with board, lodging, and washing.

SOUTHPORT INFIRMARY.—Resident Junior House and Visiting Surgeon, unmarried. Salary at rate of £70 per annum, with residence, board, and washing.

STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Resident Assistant House Surgeon for six months Salary at rate of £50 per annum, with board, lodging, and laundry.

TEIGNMOUTH HOSPITAL, South Devon.—House Surgeon. Salary £70 a year, with board, lodging, and washing.

THROAT HOSPITAL, Golden-square W.—House Surgeon. Salary at rate of £75 per annum, with residence, board, and laundry.

UNIVERSITY OF LONDON.—Sharpey Physiological Scholar. Emolument of £150 a year.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea S.W.—House Physician for six months. Honorarium of £30, with board and lodging

WALSALL AND DISTRICT HOSPITAL.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Assistant House Surgeon, unmarried. Salary £75 per annum, with board, residence, and washing. Also Senior House Surgeon, unmarried Salary £110 per annum, with board, residence, and washing.

WEST HAM HOSPITAL, Stratford, E—Junior House Surgeon for six months. Salary at rate of £75 per annum, with board, residence, &c.

ORCESTER COUNTY AND CITY ASYLUM.—Locum Tenens. Salary 3 guineas per week.

ORCESTER GENERAL INFIRMARY.—House Physician. Salary £20 per annum, with board and residence.

E Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Cheltenham, in the county of Gloucester, and at Mid-Calder, in the county of Edinburgh.

Births, Marriages, and Deaths.

BIRTHS.

PER.—On May 9th, at Sutton Court-road, Chiswick, the wife of Bertram Cooper, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

AHAM.—On May 1st, at Gwydir House, Cambridge, the wife of J. C. W. Graham, M.A. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

ACMILLAN.—On May 12th, at Prestwich, Lancashire, the wife of David Macmillan, M.D., of a son.

DEATHS.

ARNES.—On May 12th, at Bernersmede, Eastbourne, Robert Barnes, M.D.

ARNICOT.—On May 13th, at 40, Queen-street, Hitchin, Ethel, the wife of Joseph Barnicot, M.D.

RROWS.—On May 8th, at Exton Mansions, Hove, William Seymour Burrows, M.R.C.S., J.P.

ODSHAM.—On May 12th, at Weybridge, John Mill Frodsham, M.D., J.P., aged 72 years.

LLAND.—On May 9th, at Rollestone House, Horncastle, Robert Jalland, M.R.C.S. Eng., L.R.C.P. Lond., aged 70 years.

ENNAN.—At 35, Mayfield road, Edinburgh, on the 12th May, Eileen Ivy Theodora, aged 2½ years, only child of Dr. Theodore Shennan and Mrs. Shennan (née Minnie Green, L.R.C.P. & S. Edin.).

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE GOLDEN FLEECE.

WE remarked in these columns last week that in the above-named publication we were accused quite untruthfully *of sending out* advance copies of THE LANCET containing the pronouncement concerning the use of alcohol which the pamphlet sent to us for review proposed to analyse and to refute. We have now received a letter from Mr. Charles Smith, F.S.S., secretary of the British Temperance League, concerning "the medical statement in favour of alcohol" (as he terms it) which runs as follows:—

To the Editors of THE LANCET.

DEAR SIRS,—On p. 1335 of THE LANCET for the 11th inst., commenting on my reply to the above, you say: "We are accused quite untruthfully of sending out advance copies of THE LANCET *containing the pronouncement.*" Have you not here erected a windmill of the type easily demolished which you attribute to me, and then proceed to demolish it with great satisfaction as though you were demolishing an argument of mine? *Kindly look through* the pamphlet again, and you will find that it does not accuse you of anything. It runs: "Advance copies (from THE LANCET) were *issued before the day of* publication and were widely inserted in the London and provincial newspapers."

And that statement is strictly true. The day of publication of THE LANCET containing this alcohol statement is Saturday, March 30th. I enclose you herewith a sheet of the Yorkshire *Telegraph and Star* for Friday, March 29th, containing this manifesto from your columns, *citing you as its authority*, and being an exact facsimile of the document as it appeared in your *columns the following* day, even to the division into pars. and the order of the names of the signatories.

It is, as you will observe, suitably introduced with three lines of big type: "Doctors and Alcohol," "Important Manifesto," "Counterblast to Teetotal Statements." This paper was on sale in the streets of Sheffield at 3 o'clock on Friday afternoon, March 29th.

Who distributed these advance copies to the press I know not, but my information is that they were widely posted from London early on Thursday, March 28th, *in some cases being delivered* that day.

Yours very faithfully,

29, Union street, Sheffield, May 13th, 1907. CHARLES SMITH.

There is no need *for us to look through "The Golden Fleece"* again: no one can issue advance copies of THE LANCET *except ourselves, and* we repeat that the accusation is untrue. Mr. Smith's information *that copies of* THE LANCET *were widely posted from* London early on Thursday, March 28th, is, we are glad to say, correct, but it has not the significance which he calmly gives to it. Friday, March 29th, happening to be Good Friday, *we went to press* one day earlier than usual. No advance copies of THE LANCET containing the *pronouncement* upon alcohol were issued by us, and no one but ourselves can *issue* advance *copies. The statement* in Mr. Smith's letter which he qualifies as "strictly true" is *consequently* quite untrue. The cause of temperance is *one* which we have steadily and consistently supported *in our columns, and it is one* that ought not to lead to loose speaking and writing by its official advocates.

CONSULTANTS' FEES.

To the Editors of THE LANCET.

SIRS,—Allow me to ask *you* the *following question—viz.: When* a consultant is called in to see a patient with the medical man in attendance on *the case is the medical* man in attendance responsible for the payment of the consultant's fee? The question might depend on "*who called the consultant in.*" In my particular case (as a matter of fact) the son of the house telephoned *to the consultant from the* patient's house and asked the consultant to call and I would wait until he came. The consultant *now* wants me to pay the fee *to* him and I am to get it from the patient. There is no question about the fee *being forthcoming*, but *I am not of opinion that* the ordinary medical attendant is responsible for the *consultant's fee* and I shall *be* glad of an expression *of opinion* on the subject. With apologies for troubling you.

I am, *Sirs*, yours faithfully.

May 12th, 1907. ENQUIRER.

⁂ The *usual* course is for the *patient* or his friends to have the consultant's fee in readiness. It is *generally handed* to him by the general practitioner, but in our *opinion* the patient, and *not* the *general practitioner*, is responsible *for* the fee.—ED. L.

A GARBAGE MONGER HEAVILY FINED.

AT the Mansion *House recently* John Copeland of Glenluce, Wigtownshire, was prosecuted by the public health *department of the City* as the person to whom two carcasses of pigs had belonged which had been *deposited for sale at Leadenhall* Market and which were unfit for human consumption. The defendant *did not appear and counsel* representing him pleaded guilty on his behalf. The Alderman, Sir David Evans, *said that the defendant* was not a novice and marked his view of the offence by *inflicting a fin* of £30, with £7 7*s.* costs. It is to be hoped that selling diseased animals is not quite so profitable that a fine of this magnitude can be readily paid from the profits derived from other similar dealings which escape detection or which are of not so serious a character as to attract attention. Dealers in food which endangers the health or the lives of others deserve to be prevented from carrying on transactions in the public markets for a prolonged period by some means corresponding to the "warning off" which at times removes from racecourses those who cheat their fellow men.

LOATHSOME BED-STUFFING.

To the Editors of THE LANCET.

SIRS,—We were glad to notice extract from your issue regarding impure bedding. We enclose a copy of our senior partner's little publication; second issue (six or eight years ago); see page 44 *et seq.* on same subject. We question very much if some who use the word sterilised know what it means. We think prosecution under the Merchandise Act should follow false advertising.

We are, Sirs, yours faithfully,

Edinburgh, May 8th, 1907. MARTIN AND SON.

PS.—Old clothes from Scotland go over to Ireland and after Pat has worn and patched them they come back to Greenock in bales to be torn up, unwashed, and sold for bedding!

⁂ The publication referred to is entitled "About Beds and Bedding," and it contains a good deal of practical and historical information on the subject. In regard to loathsome bedding the writer rather aptly, we think, quotes Dickens's story of the "Celebrated Sassage Shop" in the "Pickwick Papers." Halves of buttons had been found in the sausages, and buttons have also been found, it is stated, in bed-mattresses.—ED. L.

A REMARKABLE TABLET.

Lady (K.) Lawson has sent us an interesting photograph of a tablet erected in a Guernsey church to the memory of Daniel and Susanne Falla and their younger son, Thomas Falla. The following is a translation of the latter part of the inscription, which is in French:—

> This Monument is erected to their memory, and to that of their younger son, Thomas Falla, Lieutenant in the 12th Regiment of Infantry, who died at the Siege of Seringapatam, the 6th April, 1799, aged 18 years 6 months and 25 days, from the effects of a wound from a cannon ball weighing 26 lbs., which had located itself between two bones in his thigh. The said wound becoming considerably inflamed the regimental surgeon, although having examined it, ignored that a bullet was enclosed, and it was only after his death, which occurred six hours after the event, that it was extracted, to the surprise of the whole army.

Lady Lawson has asked our opinion upon the occurrence thus described, but she has since supplied us with the explanation by referring us to the well-known memoirs of Captain George Elers, where the following description of the fatal injury to Lieutenant Falla is given:—

> Among the casualties in my regiment was the death of poor Falla from a cannon-ball, a twelve-pounder, from the fort of Seringapatam, three miles distant from our trenches. It rolled in and buried itself in poor Falla's groin. It was the most remarkable wound ever seen, and the general conversation of the army, for the shot was not to be seen, the flesh swelling completely over it.

It will be seen that the inscription on the tablet is totally incorrect, while the mystery implied by mention of the "two bones" in the victim's thigh disappears when we learn that the wound was not in the thigh at all. The size of the ball is more than doubled in the account on the tablet and Captain Elers's measurement may be taken as the right one. There could not have been 26 pounders employed in the siege of Seringapatam, while a 12-pound shot might conceivably bury itself among the abdominal contents and escape attention unless actually searched for. The episode after reading Captain Elers's account becomes possible, though it is none the less extraordinary. Captain Elers says nothing about the regimental surgeon having examined the wound, and we suspect that to be a further inaccuracy on the part of the author of the inscription. The medical attitude was probably one of inaction in a case where absolutely nothing could be done. The fatal nature of the injury—described in the inscription in the following words, "The said wound becoming considerably inflamed"!—was probably perceived at once by the surgeon, operative proceedings being much more limited in those days than they are now, and the unfortunate young soldier was left to die in peace.

◆

Alia Mores.—The best articles we know are those on Intoxications in vol. ii. of Allbutt's "System of Medicine," and in Osler's "System of Medicine." Most of the standard works on Insanity—e.g., Craig's "Psychological Medicine"—deal with drug habits.

Præcipitin.—Our correspondent will find the following paper useful: Welsh and Chapman: Proceedings of the Royal Society, B. vol. lxxviii., 1906. He might also refer to THE LANCET, April 6th, 1907, p. 959.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. SATURDAY (25th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

FRIDAY (24th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—Papers:—Dr. F. de Havilland Hall: Two Cases of Prolonged Pyrexia.—Dr. Gossage: A Case of Partial Heart Block.—Dr. F. W. Price: Foreign Bodies in the Bronchi. 9.30 P.M.: Annual General Meeting.

BRITISH ELECTROTHERAPEUTIC SOCIETY (11, Chandos-street, Cavendish-square, W.).—8 P.M.: Council. 8.30 P.M.: Dr. Doumer (Lille): The Fundamental Principles of Electrotherapy. An Extraordinary General Meeting will be held for the purpose of winding up the Affairs of the Society.

SATURDAY (25th).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (University of Edinburgh).—9 30 A.M.: Card Specimens and Cases will be shown. 10 A.M.: Papers will be read and Demonstrations given.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (20th).—NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques—9.30 A.M.: Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Medical Out-patient (Dr. Whipham); Throat, Nose, and Ear (Mr. Carson); X Ray (Dr. Pirie).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.15 P.M.: Sir Dyce Duckworth: Medicine. 2.30 P.M.: Operations. 3.15 P.M.: Mr. W. Turner: Surgery. 4 P.M.: Dr. StClair Thomson: Diseases of the Throat, Nose, and Ear. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 12 noon: Ear and Throat.

TUESDAY (21st).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynæcological Operations. 2 P.M.: Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin. 5 P.M.: Clinical Lecture:—Dr. Russell.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Dr. W. Ewart: Clinique. (Medical.) 5.15 P.M.: Lecture:—Mr. W. H. Clayton-Greene: Suppression of Urine and Anuria.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—10.30 A.M.: Medical Out-patient (Dr. Auld). 2.30 P.M.: Gynæcological Out-patient (Dr. Giles), Surgical Out-patient (Mr. Edmunds). Surgical Operations (Mr. Carson).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 P.M.: Dr. R. T. Hewlett: Medicine. 2.30 P.M.: Operations. 3.15 P.M.: Mr. Carless: Surgery. 4 P.M.: Mr. M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 12 noon: Skin.

Central London Throat and Ear Hospital (Gray's Inn-road, W.C.).—3.45 P.M.: Demonstration:—Dr. A. Wylie: Pharynx.

National Hospital for the Paralysed and Epileptic (Queen-square, Bloomsbury, W.C.).—3.30 P.M.: Clinical Lecture:—Sir W. Gowers: Vagal Attacks and Brain Faints.

WEDNESDAY (22nd).—Post-Graduate College (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 P.M.: Medical and Surgical Clinics. X Rays. 2.30 P.M.: Operations. 5 P.M.: Lecture:—Dr. Beddard: Practical Medicine.

Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 P.M.: Mr. P. Paton: Clinique. (Surgical.) 5.15 P.M.: Lecture:—Dr. H. French: The Vaccine Treatment of Acne and Some Points in the Treatment of Some other Common Maladies.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 P.M.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 P.M.: Dr. F. Taylor: Medicine. 2.30 P.M.: Operations. 3.30 P.M.: Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 11 A.M.: Eye. 2.15 P.M.: *Special Lecture*:—*Dr. F. Taylor*: Bronchiectasis.

THURSDAY (23rd).—Post-Graduate College (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations. 5 P.M.: Clinical Lecture:—Mr. S. Edwards.

Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 P.M.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 P.M.: Lecture:—Dr. A. P. Beddard: Diabetes.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 P.M.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 P.M.: Medical In-patient (Dr. Chappel). 4.30 P.M.: Special Demonstration of Skin Cases (Dr. G. N. Meachen).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. G. Rankin: Medicine. 3.15 P.M.: Sir W. Bennett: Surgery. 4 P.M.: Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 12 noon: Ear and Throat.

Charing Cross Hospital.—4 P.M.: Dr. I. Bruce: Demonstration (Electrical). (Post-Graduate Course.)

Hospital for Sick Children (Gt. Ormond-street, W.C.).—4 P.M.: Lecture:—Mr. Parsons: Convergent Squint.

Royal Institute of Public Health (37, Russell-square, W.C.).—5 P.M.: Special Lecture:—Prof. J. Penberthy: The Veterinary Aspect of the Tuberculosis Problem.

University of Birmingham, Faculty *of* Medicine (Medical Lecture Theatre).—4 P.M.: Post-Graduate Lecture:—Prof. Leith: The Widal Reaction, its Present Position and Value.

FRIDAY (24th).—Post-Graduate College (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynæcological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. X Rays. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin. 5 P.M.: Lecture:—X Rays.

Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 P.M.: Mr. R. Clarke: Clinique. (Eye.)

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—9.30 A.M.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 P.M.: Medical In-patient (Dr. Leslie).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 P.M.: Dr. R. Bradford: Medicine. 2.30 P.M.: Operations. 3.15 P.M.: Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 12 noon: Skin. 3.15 P.M.: Special Lecture:—Mr. McGavin: Epithelioma of Penis and Precancerous Conditions.

National Hospital for the Paralysed and Epileptic (Queen-square, Bloomsbury, W.C.).—3.30 P.M.: Clinical Lecture:—Sir V. Horsley: Surgery of the Nervous System.

Central London Throat and Ear Hospital (Gray's Inn-road, W.C.).—3.45 P.M.: Demonstration: Dr. A. Wylie: Pharynx.

SATURDAY (25th).—Post-Graduate College (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. 2 P.M.: Medical and Surgical Clinics. X Rays. 2.30 P.M.: Operations.

London School of Clinical Medicine (Dreadnought Hospital, Greenwich.)—2.30 P.M.: Operations. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 11 A.M.: Eye.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid; and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

For the United Kingdom.		To the Colonies and Abroad.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received:—*Chatham, Rochester, and Gillingham News, Standard, Daily News, Daily Chronicle, Belfast News, Daily Mail, Tribune, Western Mail, Peterborough and Hunts Standard, Hull Eastern Morning News, Bury Guardian, Daily Express, South London Press, Morning Post, Preston Guardian, Durham Chronicle &c.*

A Clinical Lecture

ON

ABDOMINAL TUMOURS ASSOCIATED WITH DISEASE OF THE TESTICLE.

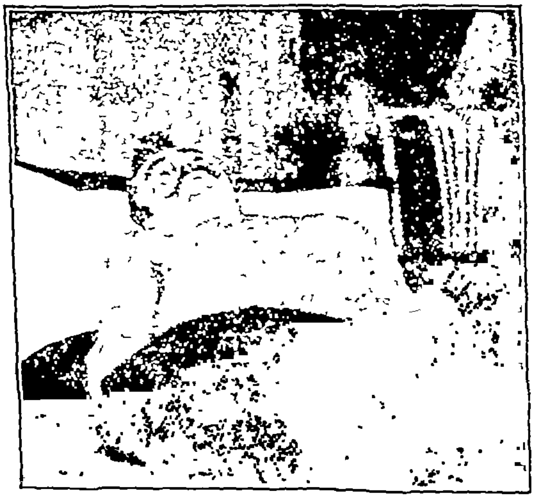
Delivered at the Radcliffe Infirmary, Oxford, on March 20th, 1907,

BY WILLIAM OSLER, M.D. OXON., F.R.S.,
REGIUS PROFESSOR OF MEDICINE AT THE UNIVERSITY OF OXFORD.

GENTLEMEN,—Not infrequently the diagnosis of an obscure affection of the abdomen is determined by an examination of the testicles. More than once in my experience the nature of a peritonitis or of an abdominal tumour has been cleared up by finding a tuberculous orchitis; or in syphilis gummata may occur at the same time in the liver and in the testicles. But it is more particularly in malignant disease of these organs that abdominal features are met with, and the case before you illustrates in a singularly complete manner many of the peculiarities of this association.

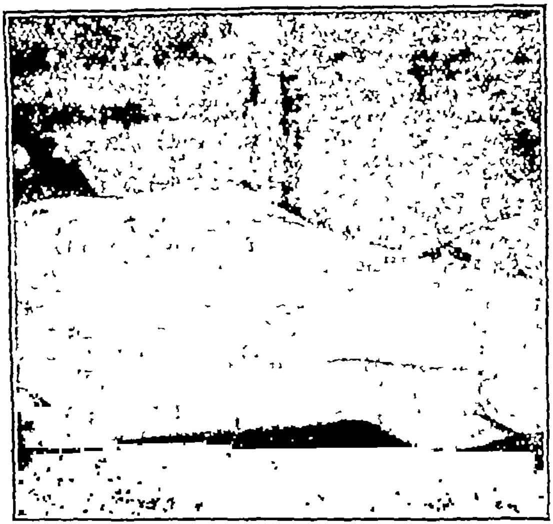
This well-built fellow, aged 22 years, with a suspicious pallor of the face, was sent by Mr. R. R. Hatherell from Kingston Bagpuze and Mr. Parker has kindly sent him for my clinique. When seven years of age he fell from a tree and injured the left testis which was transfixed by a small spike. Ever since it has been a little enlarged, but it gave him no trouble until about six months ago, when it began to grow and to be a little painful. A few weeks ago he noticed a swelling of the abdomen. He has lost about 8 pounds in weight. The left testicle is of about the size of a small orange, round, and firm; the epididymis is enlarged and there is a gland of the size of a filbert just above it, which I thought at first was the cord. There is no sign of the old injury. In both inguinal grooves the lymph glands are enlarged and hard, forming visible tumours. The abdomen presents a very remarkable appearance (as illustrated in the accompanying illustrations,[1] Figs. 1 and 2). A prominent mass occupies the left upper quadrant, lifting the costal border, and causes bulging of the eighth, ninth, and tenth ribs. Below it reaches to the level of the navel and to the right a little beyond the linea alba. It appears to descend slightly on deep inspiration, and on close inspection there is a shock-like pulsation in the whole mass and in the splenic region. On palpation the mass is very solid and immoveable, emerges directly beneath the costal border, and extends to the level of the navel, but below the limits cannot be accurately made out. To the right it reaches to the middle line but the epigastrium itself is not occupied nor does the liver appear to be enlarged. Passing deeply in the flank it cannot be grasped between the hands and moved up and down like a renal or splenic tumour. It has rounded outlines without nodules and is painless on pressure, firm, and has a feeble pulsation, not expansile, but just such as one feels in deep-seated abdominal growths. The throbbing of the abdominal aorta is felt just above the navel. There are enlarged glands both above and below Poupart's ligament on both sides. There is an enlarged gland just above the left clavicle.

FIG 1



View of abdominal tumour from the front showing the high position.

FIG. 2



View of abdominal tumour from the side.

Two very common events in connexion with malignant disease of the testicle are illustrated by this case—the influence of trauma (which in some statistics has been as high as 50 per cent. of the cases) and the very rapid generalisation. Following an injury the tumour may appear in a few months, or, as in this patient, 15 or more years may elapse. It is well to bear in mind that the course may resemble an acute orchitis. Some years ago I saw with Dr. McGill of Catonsville, a young man, aged 19 years, who had bruised one testis on his bicycle. This was followed by swelling, gradual enlargement, and the tumour persisting the organ was removed. It contained blood and much grumous matter thought to be pus. About a year later he began to fail in health and when I saw him he presented two large tumours in the upper abdominal region, evidently connected with the liver. There was fluctuation and the masses felt like sacs of pus. An exploratory operation showed the condition to be a rapidly growing soft sarcoma of the liver.

The generalisation is, in the majority of cases, through the lymphatics, and, as in this case, may take place very early. I have not sufficient experience with tumours of the testicle to say on simple examination just what variety this is, though from its firmness in places and its elastic tendency in others it is quite possible that it belongs to the remarkable group of embryomata or teratomas. I wish particularly to bring before you the characters of the abdominal tumour in malignant disease of the testicle. There are two groups of cases: (1) the tumour is a secondary involvement of the lymph glands, as in the case before you; and in the other (2) the tumour is primary involvement of the retained testis in a monorchid or a cryptorchid. To understand the relation of the secondary tumours you must bear in mind that the lymphatics of the testicles discharge very high up into the aortic lumbar glands—on the left side into three glands to the left of the aorta just below the renal artery, on the right side into from three to five glands to the right of the vena cava and between it and the aorta. The secondary tumour is, therefore, above the level of the navel, and usually begins in the upper quadrant of the abdomen on the

---

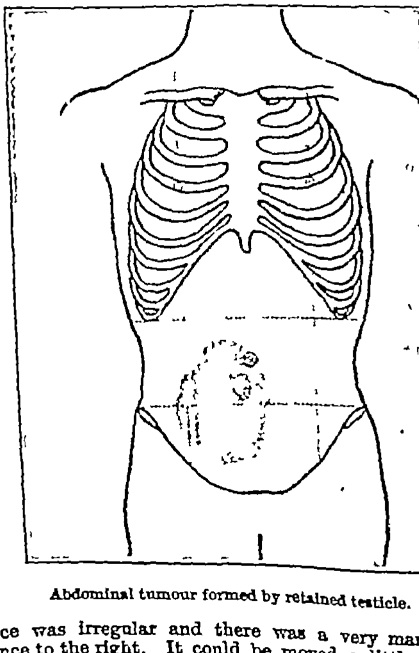
[1] These photographs were taken by Dr. R. H. Sankey on April 9th. The tumour has grown very much.

resistance on palpation. Occupying the central upper portion of the abdomen is a solid, irregular mass; to the right it extends far over into the flank, below to the level of the spine of the ilium. To the left it does not extend so far, but in the epigastric and upper umbilical regions it extends as far as nipple line. There is bulging above the navel. It can be felt most pronouncedly midway between the navel and ensiform cartilage. Outline between mass and liver not clearly defined. It is very resistant and immobile and does not descend with inspiration or posture. On bimanual, the mass seems an unusually deeply placed tumour. Everywhere gurgling in the intestines can be felt, but the edge of the liver is not palpable. The right rectus is more rigid than left. The upper level of liver dulness is on a level with the upper margin of sixth rib and extends to costal border." The patient was discharged unimproved on March 28th, 1898.

In the second group, not nearly so common, the tumour originates in the retained testes of a monorchid or a cryptorchid. The following cases have come under my observation; two of them in the surgical clinique of the Johns Hopkins Hospital my colleague Halsted allowed me to demonstrate to my clinical class.

CASE 1. *Cryptorchismus; abdominal tumour; diagnosis of sarcoma of retained testicle; removal; rapid recurrence.*—A man, aged 29 years, Surgical No. 2900, was seen in Dr. Halsted's ward with Dr. Bloodgood on March 21st, 1894. The patient was a resident of Maryland and had been at several cliniques seeking advice as to the nature of his trouble. He was a medium-sized, slightly built man, somewhat effeminate looking in the face, with a fair-sized moustache but with very little hair on the cheeks. He had been pretty well up to six or eight weeks ago, when he noticed for the first time a lump in his abdomen, since which time there had been gradual enlargement and he had lost in strength and weight. He looked pale; there was no fever; the pulse was good. The abdomen was uniformly distended, having the appearance of an ordinary ascites; the superficial veins were not enlarged. On palpation it was moderately tense and fluctuation was readily obtained. In the middle line on deep palpation a firm, hard body was touched which was felt to occupy the right lower quadrant of the umbilical region and the greater portion of the hypogastric, extending, however, much more to the right than to the left side. The surface was irregular and there was a very marked prominence to the right. It could be moved a little from side to side, but there was too much fluid in the abdomen to make any satisfactory bimanual palpation. It was hard and resistant and in the process of dipping for it with the tips of the fingers it evidently yielded and could be depressed from one side to the other. The scrotum was empty but somewhat distended; the inguinal canals were open and the ascitic fluid passed directly into the sac of the scrotum. Examination by the rectum revealed the presence of a hard indurated mass on the right side. Considering that the patient was a cryptorchid and the known proneness of the retained testicle to new growth, the diagnosis of sarcoma of one of the intra-abdominal testicles was made. On the 24th Dr. Halsted operated; he removed the ascitic fluid and found a tumour formed by the enormously enlarged and sarcomatous right testicle. The organ had retained its shape; a groove separated the body from the greatly enlarged epididymis. The tumour was greyish-white in colour, firm and hard in some places, soft and partially cystic in others. A portion of growth on the pelvic floor could not be removed. The patient left the hospital on April 14th very much improved in his general health, but returned on May 12th with signs of recurrence.

FIG. 4.



Abdominal tumour formed by retained testicle.

CASE 2. *Monorchid; tumour in the right side of abdomen; ascites.*—The patient was a married man, aged 46 years. Surgical number 2992. He was admitted on April 17th, 1894. His family history was negative. His personal history was negative, except for alcohol to excess until 41 years of age. The present illness began about eight months ago with a sharp sudden pain in the left side of the abdomen of very excruciating character, which lasted about five minutes. This was followed by a soreness for several days in the left ilio-costal space. About three weeks after this attack he noticed a hard tumour in the left side of the abdomen which was painful on pressure. For some months prior to September, 1893, the patient had noticed increasing difficulty in moving his bowels, and this had progressively increased, and now only strong purges or enemata were successful. About December, 1893, he had pain around the neck of the bladder on micturition; now it occurred only occasionally. The tumour had not increased perceptibly in size. He said he had become paler and had probably lost weight. There had never been any blood in the urine or stools. The patient was an emaciated, cachectic man, with pale mucous membranes; the radial pulse was small and weak, with the vessel wall decidedly sclerosed. There was no general lymphatic enlargement. The abdomen was distended and prominent, particularly in its lower half, where two tumour masses were seen, one in the right inguinal region and the other more to the left of the navel. The abdomen was soft in its upper half, but below and to the right of the navel was felt a large, hard tumour with irregular margins, painful on deep pressure. The small nodule in the diagram corresponds to the epididymis and was more painful than the rest of the mass. The growth was not moveable nor was it adherent to the skin. There was much fluid in the abdomen, which had been increasing since admission. The difficulty in moving the bowels had also increased. The inguinal glands were slightly enlarged and tender. The left testicle was absent and could not be felt, while the right was normal. The inguinal canal on the left side was open, though the internal ring was barely felt. Blood: 4,200,000 red cells, 6500 white. Since admission the fluid had increased in the abdomen and the patient had become weaker. The urine was clear on examination. The patient was discharged unimproved on May 7th as Dr. Halsted refused to operate.

CASE 3. *Monorchid; tumour in the right lower quadrant of the abdomen; operation.*—On April 25th, 1900, I saw with Dr. Henry Jackson and Dr. Cabot in Boston a robust healthy man, aged 45 years. He had had for years an undescended testis on the right side, which had once been just at the inner ring but subsequently had receded. For three or four months he had had irregular pains in the abdomen, thought to be due to gas, chiefly in the right iliac fossa. About six weeks previously Dr. Jackson noticed the presence of a lump in this locality and three weeks previously Dr. Cabot operated and found a large, solid tumour corresponding to the testis but passing deeply and surrounding the vessels in such a way as to make it inoperable. The patient was a healthy-looking man, though he had lost a good deal in weight. He did not look at all cachectic. The hypogastric region was a little prominent and there was a bulging just below and to the right of the navel. On palpation the right inferior quadrant of the abdomen was filled with a solid mass. Above it extended beyond the level of the navel and to the left about the middle line. It was fixed, slightly irregular on the surface, not painful. The prominence noticed was evidently the colon pushed up to the top of the mass. The

sicles. In other cases the spots enlarge and fuse, a considerable area of the cornea becoming denuded of epithelium, d this area continues to increase, showing a crenated rder. In other cases, again, the typical dendritic ulcer is rmed. Grey striæ extend in one or more directions from e minute ulcer, grow longer and throw out lateral branches, ally breaking down. I do not think that it is correct to nsider herpetic all ulcers of the cornea which have a perficial resemblance to the dendritic ulcer. In many ses they are traumatic and heal rapidly and the term dendritic," though it describes their appearance, is best ot applied to them, for it has come to have a specific eaning attached to it.

All these herpetic ulcers of the cornea are superficial and ever extend in depth unless they become infected. In most ases they involve Bowman's membrane and leave permanent aint nebulæ, though the scars may be so faint as to cause ittle or no impairment of vision in spite of the fact that hey are generally in the pupillary area. Characteristic of ll forms of herpetic keratitis is the fact that the sensitiveess of the cornea is depressed. If the cornea is touched ith a wisp of cotton wool there is much less response in he form of reflex closure of the lids on the affected side han on the sound side.

These types of keratitis associated with herpes febrilis are ess likely to be accompanied by complications than those ound in ophthalmic herpes. It is said that the cornea is more prone to be attacked in the latter group when the nasal erve is affected than when it escapes, possibly due to the fact that the nerve-supply of the uveal tract is derived through the lenticular ganglion from a branch of this nerve. The rule is certainly not an invariable one. Iritis not infrequently occurs in ophthalmic herpes corneæ, and there may even be severe iridocyclitis, with precipitates ("k. p.") upon the back of the cornea. Indeed, it is the rule for some slight diminution in the intra-ocular pressure to be present, pointing to interference with the processes of secretion of intra-ocular fluid by the ciliary body. I do not think too great importance should be attached to this statement, for the depression in the intra-ocular tension is seldom very marked.

Allied to these typical forms of herpetic keratitis are other cases which are not vesicular but which generally follow some febrile attack and pursue a course strikingly similar to true herpes. One such case I am able to show you. About a week after a febrile attack, probably influenza, this young woman's left eye became inflamed. On examination it was found that there was a group of yellowish-grey spots of about the size of a small pin's head, slightly above the centre of the cornea. They were separated from each other by greyish areas, which on magnification with the loupe showed fine striæ. Several of the spots showed staining with fluorescein at this period. The other case, which I have already referred to as occurring at University College Hospital, was almost identical both in history and appearance.

Of the forms of keratitis previously described by other writers these cases most resemble the condition known as superficial punctate keratitis (Fuchs). They differ from most of Fuchs's cases in that these are generally bilateral, and there is no loss of substance so that they do not stain with fluorescein. In the University College case I scraped the cornea and made a film and a culture on serum. No organisms could be found in the film and the culture was sterile, possibly owing to the previous use of cocaine. Both cases were treated by cauterisation with pure carbolic acid and both are very markedly improved. The irritation and redness of the eyeball have almost disappeared but the spots are quite plainly visible, though they no longer stain. They will probably persist for many weeks or even months and it is not unlikely that recurrent attacks of irritation and possibly fresh spots may occur.

There are other allied conditions which I cannot now discuss in detail. Some cases show an extreme tendency to desquamation of the corneal epithelium, so that when the patient wakes in the morning the greater part of the corneal epithelium is torn off and great pain is experienced. There are also cases of filamentary keratitis occurring in otherwise sound eyes, which are probably similar in nature and pathology.

The pathology of these herpetic and parerpetic conditions is of much interest. As long ago as 1862 herpes zoster was attributed to lesions of the posterior root ganglia (von Bärensprung[2]). Wyss[3] (1871), Sattler[4] (1875), and Kaposi found hæmorrhage and infiltration of the Gasserian ganglion in herpes ophthalmicus. The subject was attacked and exhaustively investigated by Campbell and Head[5] in 1900. 17 cases of herpes zoster were examined at all periods, from a few days to one and a half years after the eruption. In all the acutest cases hæmorrhages into the ganglion were found, usually small, but surrounded by a considerable amount of inflammatory exudation. The ganglion cells were destroyed to a varying extent and in the later cases parts of the ganglion were markedly sclerosed. Three cases of zoster within the territory of the trigeminal were investigated and in all changes were discovered in the Gasserian ganglion.

There is therefore good evidence to believe that ophthalmic herpes is dependent upon definite lesions in the Gasserian ganglion, which is morphologically a dorsal root ganglion. It is probable that the pathology of the various types of cases referred to in this lecture is fundamentally the same, different as are the clinical features in certain details. The frequency of a febrile onset is striking, and though herpes febrilis does not manifest the same accuracy of distribution according to nerve supply that is found in herpes zoster it is yet probable that the causal lesion should be referred to the peripheral sensory nerves and most likely to their ganglia rather than to their terminations. Herpes zoster is the outcome of an intense and concentrated attack upon certain dorsal root ganglia. Herpes febrilis and the parerpetic affections of the cornea (and possibly of other parts of the body) may reasonably be regarded as a less acute, more widely diffused attack of a similar nature. In herpes zoster parts only of an individual ganglion are likely to be destroyed. In the parerpetic forms we must predicate less destruction of tissue and abolition of function, but finer localisation, often combined with wider diffusion, of partial derangement of tissue and disorder rather than demolition of function.

Granting the accuracy of our views as to the site of the lesion there remains the extremely difficult task of explaining its manifestations. We are accustomed to regard sensory nerves as conveying only afferent impulses and it is difficult to imagine how even an inflammatory block in the course of the nerve can produce the pathological changes in structure at its distant terminations. The trophic control of the nerve fibres themselves by the dorsal root ganglion is a well-established fact. The trophic control of the tissues supplied by the fibres, early invoked to account for the phenomena of neuropathic keratitis, &c., is doubtful, if indeed it may not be said to have been disproved. Several cases of neuropathic keratitis following extirpation of the Gasserian ganglion for trigeminal neuralgia have come under my observation. If suitable precautions are taken during and after the operation this complication is infrequent, a fact which goes far to disprove the trophic theory. It is impossible to enter into a discussion of the experimental investigations upon the subject here. A careful examination of the facts derived from this source leads me to agree with the conclusions arrived at by Wilbrand and Sänger.[6] It is probable that neuropathic keratitis is due neither to abrogation of trophic influence nor to this cause assisted by loss of sensation and the invasion of pathogenic organisms. There is reason to believe that in all those cases in which the cornea becomes ulcerated after division of the fifth nerve the cut ends of the nerve are subjected to some abnormal irritation, either by blood clot, pus, or other agent. This view fits in well with the manifestations of herpes and parerpetic affections. If, then, there is undue irritation in the course of the nerve, as for example at the ganglion, how are we to explain the distant effects? They must be due either to the transmission of impulses along the nerve in the reverse direction to the normal afferent impulses or to the transmission of deleterious agents along the nerve.

There is some experimental evidence of the transmission of impulses along sensory nerves in the opposite direction to that of the normal impulses. In 1876 Stricker showed that vaso-dilatation of the hind limb of the dog occurred when the peripheral ends of the divided posterior roots of the sixth and seventh lumbar nerves were stimulated. In 1900 Bayliss,[7] contrary to his expectation, confirmed these results

pain, sensations of heat above 45° C., and sensations of cold below 20° C. Loss of epicritic sensibility abolishes recognition of light touch, discrimination of compass points, appreciation of differences in size, and discrimination of intermediate degrees of temperature from 25° to 40° C. After division of a sensory nerve protopathic sensibility is restored in about six weeks if the ends of the nerve are placed in apposition. Cutaneous sores which may have occurred in the area affected from injury, &c., show little or no tendency to heal until protopathic sensibility is restored, when healing rapidly ensues. Epicritic sensibility requires much longer for restoration and the time varies with the position of the affected part. The areas of protopathic and epicritic sensibility are *not* identical. In any peripheral nerve the distribution of the protopathic fibres usually overlaps greatly the area supplied by the fibres of the adjacent nerves, whilst the distribution of the epicritic fibres in the larger peripheral nerves, such as the median and ulnar, overlaps only slightly. It is found for certain peripheral nerves or nerve groups—such as the median, ulnar, or pre-axial nerves of the arm—that each of these forms a unit of the epicritic system, whilst the protopathic unit must be sought in one or more posterior nerve roots, for the nearer the lesion is situated to the posterior roots the more extensive and definite is the loss of protopathic sensibility. Similarly the more nearly the injury divides one of the nerve groups the more definite and extensive is the epicritic loss.

Lesions of the spinal cord show that there is a complete redistribution of afferent impulses, so that peripheral impulses are transmuted into those of the secondary level of the afferent nervous system. This transmutation and recombination take place on the same side as that by which the impulses enter the cord. The secondary paths for sensory impulses then cross with greater or less rapidity, so that ultimately all except those subserving the sense of passive position and movement and tactile discrimination have passed to the opposite side within the limits of the spinal cord. Even these sensory impulses cross after reaching the nuclei of the posterior columns. At the same time, within the cord afferent impulses become separated into sensory and non-sensory. Of the latter many pass up in the secondary system of the direct cerebellar tract to reach the cerebellum.

It has been mentioned that skin lesions in an analgesic area show little or no tendency to heal until restoration of protopathic sensibility has taken place. There is further evidence that these peripheral lesions are in some manner under the control of the protopathic system. Head has previously shown that there is a close correspondence between the distribution of the tenderness caused by irritation through visceral disease of the segments within the cord and the areas marked out on the skin by the eruption of herpes zoster. He has also shown that herpes zoster is due in most cases to acute inflammation of a posterior root ganglion, whereas the tender areas in visceral disease are due to irritation of intramedullary segments. But, though all the cells and the fibres peculiar to them must be affected by the profound inflammation of the ganglion, one system only, so far as we know, can produce antidromic effects upon the skin, and these are the fibres shown by Bayliss to have their cells of origin in the ganglion of the posterior root. Head and Bayliss have now shown that these antidromic fibres are capable of excitation in the divided nerve of a cat five weeks after it has been reunited to the central nervous system. Hence, it may be considered proved that the power of producing changes in the skin of the periphery is a function of fibres which run in the protopathic system.

Without discussing the bearing of these researches upon the afferent impulses in the trigeminal nerve and their redistribution within the central nervous system, for which the material is indeed as yet insufficient,[11] it is clear that they have an important bearing on the pathology of neuroparalytic keratitis. Whether such so-called trophic lesions can be caused by the abolition of antidromic impulses alone —i.e., whether antidromic trophic impulses exist as a physiological phenomenon—is a question which may be set aside for the present, though the evidence in favour of such impulses is undoubtedly increased. What seems to be certain is that abnormal stimulation of the protopathic fibres in or near the ganglion produces antidromic impulses which have a deleterious effect upon the nutrition of the peripheral organs. The researches, in fact, bring forward strong evidence in support of a theory already suggested by Wilbrand and Sänger—viz., that neuroparalytic keratitis is due to irritation of the distal end of the cut or diseased trigeminal nerve. This theory explains better than any other all the diverse clinical facts which have accumulated. It explains the absence of keratitis in those cases in which it does not occur. Neuroparalytic keratitis may occur in association with retained corneal sensibility. Here the afferent tract is still open, but an irritative lesion has set up abnormal antidromic impulses in the protopathic system. There may be hyperæsthesia of the cornea with keratitis. Here not only is the afferent tract open but it is subject to abnormal stimulation either at the periphery or at the site of the lesion, and abnormal antidromic impulses are also set up. There may be anæsthesia dolorosa. This is due to irritation of the proximal end of the cut or diseased nerve, whilst antidromic impulses are set up in the distal section.

In conclusion I may perhaps be permitted to express the admiration which we must all feel for the brilliant results which have been obtained by Dr. Head and his fellow workers from their extremely laborious researches.

TORSION OF THE TESTIS.*

BY HUGH M. RIGBY, M.S. LOND., F.R.C.S. ENG.,
SURGEON IN-ORDINARY TO H.R.H. THE PRINCE OF WALES; ASSISTANT SURGEON TO THE LONDON HOSPITAL; SURGEON TO THE POPLAR HOSPITAL FOR ACCIDENTS;

AND

RUSSELL J. HOWARD, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS, ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN; ASSISTANT DEMONSTRATOR OF ANATOMY, LONDON HOSPITAL MEDICAL COLLEGE.

THE following note is the outcome of the examination by us of nine cases of torsion of the testis that have come under our immediate notice. Three of these were under our care and the other six we are able to publish by the kindness of the members of the surgical staff of the London Hospital. Four of the specimens are now in the museum of the London Hospital Medical College.

Etiology.—Age.—Torsion of the spermatic cord may occur at any age, Taylor[1] reporting a case at birth, Howse[2] one at 48 years, and Lexer[3] a case in a man of 60 years. In our nine cases the youngest was four months old and the oldest 24 years, the average age being $12\frac{7}{15}$th years. In 23 cases taken without selection from the literature, 17 occurred in patients before the age of 20 years and eight before the age of ten years. The condition is therefore most common in young subjects.

Side.—In 40 cases taken from the literature the right testis was affected in 22 cases and the left in 18, giving a slight predominance to the right side; the predominance of undescended testis is also on the right side.

Position of the testis.—The earlier cases of torsion of the cord were chiefly noted in the partially descended testis, but later many cases have been reported in the fully descended organ. In our nine cases four occurred in the fully descended testis, four in the inguinal testis, and in the other the testis could, and did, easily ascend into the inguinal canal. In connexion with the last case it is interesting to note the ease with which the testes of the young can be made to ascend into the canal by contraction of the cremaster—a condition described by Corner[4] as "moveable testis" and which he believes to be due to the *presence of a* long mesorchium. In the 23 cases the testis was fully descended in nine cases and in 12 cases was in the inguinal canal. The position in the other two cases was not stated. Stiles[5] has described a case of torsion in an abdominal testis, but the organ was the seat of a malignant growth. There had been five attacks of pain, vomiting, and frequency of micturition before the testis was removed.

Cause.—The predisposing cause is a congenital abnormality of the attachment of the testis to the spermatic cord, with, perhaps, a voluminous condition of the tunica vaginalis and will be more fully referred to under the pathological anatomy. The exciting cause is not certainly known.

---

[11] Much material for such a discussion has been collected by Dr. Morrison Davies from an exhaustive *investigation* upon 60 cases from which the Gasserian ganglion had been removed. The paper will shortly be published in *Brain*.

* The superior figures are references to the bibliography at the end of the article.

and there was complete absence of testicular sensation. Eve[12] watched a case that refused operation and at the end of a month found that the boy was well except that the body of the testis was wasted. In this case the testis was undescended.

But this marked degree of atrophy is not invariable. In Case 1 of our series on examination six months after the torsion the body of the testis was a little flabby and smaller than that of the opposite side, but testicular sensation was present and there seemed no fear of further atrophy unless the patient had another attack. In Case 7 six weeks after the symptoms the testis was harder than normal but not smaller. Cases of recurring torsion also may have several attacks without atrophy supervening, as mentioned above. Atrophy may, however, follow, even if the twist be quickly undone. Delafontaine[13] untwisted the cord a few hours after the onset of symptoms and atrophy followed. Nash's case was untwisted one hour after the onset of the pain and two years later his patient reported "the right testicle is considerably smaller than the other."

A rarer condition than atrophy is gangrene of the testis with sloughing of the organ which may follow operation or occur without anything being done. Johnson's case with emphysematous crackling has been referred to under Diagnosis. Davies-Colley[14] untwisted the cord in one case and stitched the testis into position but the organ sloughed. In Keen's case pyogenic organisms were found in *the fluid of the sac.* Scudder,[15] in reporting on 32 cases collected from the literature, gave the results of seven cases not operated upon: in three the testis sloughed, in two it atrophied, and the result was not ascertained in the remaining two. Subsequent cases show a much better result. We saw no case of sloughing in the four unoperated cases reported by us. Sloughing seems particularly likely to occur in those cases which are complicated by hernia and is perhaps due to infection of the tissue with the bacillus coli communis which enters it from the gut. That atrophy of the testis is more likely to occur than gangrene is borne out by the well-known method of sterilising animals—viz., twisting the spermatic cord.

Prognosis.—As far as we are aware no fatal case has yet been reported of torsion of the testis, either with or without operation.

Pathological anatomy.—It is into the question of the pathological anatomy of this condition that we wish to enter somewhat fully, because in the cases reported we do not think it has always been accurately and sufficiently described and because the abundance of material placed at our disposal by the kindness of Dr. Arthur Keith and the *Museum Committee* of the London Hospital Medical College has enabled us to verify and to connect many of the facts reported by *other observers.* In the first place, we desire to make full acknowledgment of the help we have received from the very lucid and able articles by *Going and Keith* and Edington.

Considering the comparative rarity of this condition—although it is not so rare as was formerly supposed—the manner in which the normal testicle is attached, and the fact that the condition is so frequently met with in the partially descended testis, it is obvious that for torsion to occur the testicle must be attached to the spermatic cord in some abnormal way. That this is so has been pointed out by many observers, Eve, Corner, McAdam Eccles,[16] Keith, Edington, and it is into this abnormal attachment that we shall first inquire and verify each step by *reference to* specimens which we have personally investigated.

One of the first difficulties that presents itself is, as is pointed out by Keith and Edington, that various writers have used the term mesorchium in different senses, so that first it is necessary to define *what we* shall mean by this term. The accompanying diagram (Fig. 1) taken from Keith's "Embryology and Morphology," *p. 104, shows* that the genital gland (testis) and the Wolffian *duct* (vas and epididymis) has each its own fold of peritoneum, the fold attaching the testis being the mesorchium, *but that* the two folds join to form a common attachment to the posterior abdominal wall, the common urogenital mesentery. In the normal testis the epididymis becomes closely attached to the body of the testis, so that the mesorchium practically ceases to exist, whilst the common urogenital mesentery remains as the fold of the processus vaginalis, in which the spermatic artery runs to both the epididymis and the body. In some testes and more particularly in the partially descended testis, the mesorchium persists as a distinct fold of serous membrane passing between the epididymis and the body and contains the spermatic artery, the spermatic veins, spermatic nerves and the vas efferentia (Fig. 1). It will be seen in this same figure that the common urogenital mesentery is also longer than usual—a condition common in the partially descended testis and to be referred to later.

The usual attachment of the common mesentery is to the whole length of the epididymis and body except for a small part of the globus major (Fig. 7) and this attachment is seen in the still undescended testes of the fœtus as well as in the testes the descent of which is delayed in the inguinal canal. On dissecting the common mesentery of a case of partially descended testis with normal attachments in a boy aged 19 years, the following condition was found (Fig. 6). The spermatic artery running down in the fold of peritoneum, in which were also found the spermatic veins, reached the epididymis at the junction of its middle and upper thirds or even nearer the globus major. One large branch of this artery entered the epididymis to supply it, while the artery itself passed under the epididymis to supply the body of the testis, entering it well above the middle. At the lower part of the fold the gubernaculum testis was attached to the lower part of the body of the testis and to the globus minor and then passed downwards to be attached to the scrotum. It is said that this band may be absent in partially descended testes, and it is here necessary to refer briefly to the attachment of the fold containing the vessels (the plica vascularis), the gubernaculum testis, and the processus vaginalis. The *processus vaginalis forms* as a finger-like protrusion from the peritoneal cavity which grows downwards into the scrotum before the descent of *the testis.* It is quite free from the tissue of the scrotum, from which it can be readily removed in a full-time fœtus with scarcely any dissection. The testis is carried down *later behind* the protrusion of peritoneum by the growth of the gubernaculum testis which is attached to the lower pole of the testis and to the globus minor. The spermatic vessels grow down with the testicle and lie *in a fold* of peritoneum, the *plica* vascularis, which in the female forms the pelvo-ovarian ligament. A fold of peritoneum, the plica gubernatrix, continues this fold to the groin. These structures are seen in Fig. 2, also from Dr. Keith's book (p. 128). In some cases of partially descended *testis* the epididymis is exceedingly lengthened, the globus minor being carried down *far*

opening but in Case 6 it was shut off from the serous cavity. In both cases it was voluminous. It contained two or three drachms of blood-stained fluid, the vessels in the wall were very congested, and patches of blood extravasation were present. The vessels of the spermatic cord above the twist were perhaps a little congested but it could be described as normal. On opening the sac the testis was seen to be of a dark maroon colour, both body and epididymis being deeply congested. The body of the testis was in front and the epididymis behind, so that the parts retained their normal relationship, but the organ as a whole was inverted so that the globus major and the stalked hydatid of Morgagni were below and opposite the attachment of the spermatic cord. This condition of inversion of the testis has been described by Curling [17] under the name of reversion. It must be distinguished from retroversion, sometimes called inversion, in which the epididymis is in front and the body behind and which occurs in about 1 in 20 testes otherwise normal.

FIG. 7.

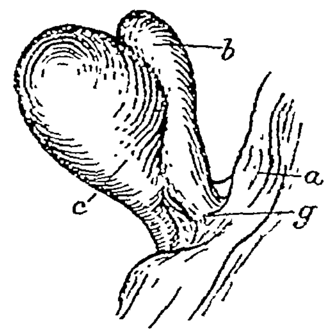
Between the body of the testis and the epididymis there was in Case 6 a dark rounded mass of the size of a hazel nut which was the mesorchium with a large mass of effused blood between its two layers. This swollen mesorchium was not so apparent in Case 8, in which the twist was not so acute, and was almost absent in two of our cases in which the epididymis was closely attached to the body, whilst in a fourth case it was well marked. Other specimens seen by us have also shown this effusion, which depends upon whether the testis has an elongated mesorchium or not, the presence of which we think has little to do with the condition of torsion.

On examining the intra-tunical portion of the cord a sharp axial twist was seen to have taken place near the attachment of the spermatic cord to the testis, the twist occurring at the place marked by the arrow in Fig. 9. When the twist was unravelled it was seen to have involved the plica vascularis with the spermatic vessels and the junction of the globus minor with the vas, and in the twist itself these structures were thinned out. The twist is therefore of the intra-tunical portion of the spermatic cord and we do not think that in man there is any distinction between torsion of the testis and torsion of the cord as suggested by Mr. Going.

We have now to connect the anatomical conditions found in the non-twisted testis with those found in the organ the cord of which has undergone torsion. It is probable, and was certainly the case in all the specimens examined and seen by us, that the congenital abnormalities present in all cases of torsion of the cord, whether the testis has fully descended or not, are: (1) the abnormal attachment of the common mesentery and vessels to the lower pole of the body of the testis and the globus minor so that the testis is attached by a narrow stalk instead of by a broad band; (2) the elongation of the globus minor; and (3) the capacious condition of the tunica vaginalis. Keith has suggested that the inversion of the testis takes place at the moment of the twist, whilst Edington, whose case was inverted, in his description of Sir Hector Cameron's case, figures the testis as already inverted. We believe that the inversion occurs before the twist for the following reasons: 1. When we undid the twist after removal of the testes the organs were still inverted. 2. That in the cases that have been untwisted at operation nothing has been said about altering the position of the testis. 3. That in cases untwisted without operation a simple twist from left to right or right to left has been made and the symptoms have been relieved. A possible exception to this might be van de Poel's [18] case, in which the action for relief of the pain is described as "stroking the cord upwards and lifting the testis upwards and rotating." 4. Langlet [19] found after untwisting the testis at operation that it was still inverted. 5. From the conditions found in the above described partially descended testes.

FIG. 8.



Retained testis in a full term anencephalic fœtus. *a*, Plica vascularis. *b*, Globus major. *c*, Body of testis. *g*, Globus minor.

A reference must here be made to the contention that torsion is due to the absence of the middle part of the gubernaculum testis [20] that fixes the testis to the bottom of the scrotum. That this band is absent we are inclined to doubt, certainly traces of it could be found in the two cases of torsion we fully dissected and it could also be easily demonstrated in all the cases of undescended testis we examined. That its attachment is abnormal we believe and to it we attribute the elongation of the globus minor. The amount of the twist varies considerably: in some cases only half a turn occurs, whilst in others four half turns have been

left testis so completely atrophied as to be difficult to make out. Not knowing the history, the case would be diagnosed as abdominal retention.

CASE 4.—The patient was aged seven years. Retained testis. Right side in inguinal canal. Three days acute pain. Vomiting. Bowels open. Painful, tender swelling right inguinal region. Scrotum red and œdematous. No testis in scrotum. Right retained testis removed. Healed by first intention.

CASE 5.—The patient was aged two years. Retained testis in inguinal canal. 48 hours pain and vomiting. Tender, painful swelling groin. Left retained testis removed. Healed by first intention.

CASE 6.—The patient was aged 34 years. "Ruptured" right side since eight years old; wore truss three to four years but hernia descended. On March 31st he slipped and "hernia" came down and gave him pain. Patient went to bed and part became swollen and painful. Vomited. Bowels open. On April 3rd taxis tried under anæsthetic. Bowels open; passed flatus readily. On admission on April 4th lump right inguinal region 4 inches by 1½ inches, tender, dull on percussion, impulse on coughing but not expansile. Right testis not in scrotum. Left testis normal. Treatment: Rest; lead lotion for eight days. Pain subsided; patient quite well. Swelling still present. Right orchidectomy. Healed by first intention.

CASE 7.—The patient was aged seven months. Pain and swelling right side of scrotum, one week. No cause. Left testis slight hydrocele. Right testis swollen and tender. Differentiation between body and epididymis impossible. Cord thickened. Translucency. Tunica vaginalis tapped; blood-stained fluid removed. Testis enlarged, body and epididymis indistinguishable. Two weeks later right testis hard, tender. Cord thickened. Scrotum red and œdematous. Two weeks later testis still hard. One month later slight hydrocele right side. Tapped; clear fluid. Testis still a little hard. No tenderness. Scrotum normal.

CASE 8.—The patient was aged ten years. On Dec. 7th, 1906, he was in bed asleep when sudden pain occurred on left side of scrotum. Found left testis ascended, could not get it down; next morning testis descended, pain ceased. Did not vomit. Bowels opened with medicine after pain ceased. On Dec. 10th testis again ascended; severe pain. Did not vomit. Admitted to hospital 12 hours later. The left testis was in habit of "ascending" and would stay up for three-quarters of an hour at a time and patient was in habit of pulling it down, but there was no pain. Right testis always descended; normal. Tender swelling, left inguinal region. No differentiation between body and epididymis. Patient was asleep when first seen by one of us. Testis removed. Healed by first intention.

CASE 9.—The patient was aged 16 years. Three weeks previously sudden attack of pain in left groin without cause. No vomiting. Testis undescended. Present condition: no pain or tenderness and no symptoms of any kind. Left side: swelling at upper part of left side of scrotum, soft below with hard nodule above. Some translucency lower part of the scrotum. No impulse on coughing. Right testis normal. Operation.—Twist half a turn of the intra-tunical portion of the spermatic cord. A very long epididymis and common mesentery. Parietal portion of tunica vaginalis removed. Testis placed in bottom of scrotum and fixed with stitches. This case was operated upon as the diagnosis was doubtful. It is too early at present to say anything about the result.

ON HYPOPHARYNGOSCOPY.[1]

BY P. TETENS HALD, M.D.,
ASSISTANT SURGEON TO THE EAR AND THROAT CLINIC OF THE KOMMUNE HOSPITAL, COPENHAGEN.

IN this paper I propose to give a description of a new and excellent method of inspecting the laryngeal part of the pharynx, the hypopharynx as it is also called, and especially the lower portion of it, situated behind the lamina of the cricoid cartilage. The method originated in that clinic which during the last few years has produced most valuable work in rhino-laryngology—I mean Killian's in Freiburg, whose chief assistant, von Eicken, devised and perfected the method. He described and demonstrated it at the meeting of German scientists and medical men in Stuttgart in 1906 and has just published an account of it.[2] For my own part I had the privilege of seeing von Eicken use the method during a visit I made a couple of months ago to Killian's clinic.

As will be remembered, the pharynx is divided into three parts: a nasal part (epipharynx), an oral part (mesopharynx), and a laryngeal part (hypopharynx). The limit between the first two is formed by the soft palate when in a horizontal position and that between the two latter parts by a plane through the body and cornua majora of the hyoid bone.[3] The hypopharynx reaches downwards to a plane passing through the lower margin of the cricoid cartilage.[4]

Of these divisions the mesopharynx, or at least the greater part of it, has certainly been inspected by medical men as long as they have existed. The epipharynx has been open to inspection since 1858 (Czermak). From about the same period it has been possible to examine with the laryngeal mirror the *upper* laryngeal part of the pharynx, on the anterior wall of which the epiglottis, the arytenoid cartilages, the ary-epiglottic folds, the pyriform recessus, &c., are to be seen. As a rule, however, one cannot see further down than the upper border of the lamina of the cricoid cartilage. The *lower* laryngeal part of the pharynx, which lies behind the lamina of the cricoid cartilage (pars cricoidea pharyngis, as it might appropriately be called), has therefore as yet not been accessible to the eye with any certainty. Nevertheless, it is of great importance to be able to inspect this particular region easily and without danger to the patient. Let me only recall to mind the fact that this is the narrowest place in the upper part of the digestive tube and that therefore foreign bodies often impact themselves here and that the localisation in this region of benign or malignant new growths of tuberculous or syphilitic ulcerations and of pressure-diverticula (Zenker) may occasion considerable difficulties of diagnosis, which render it of enhanced value to be able to make use of the sense of sight in this region. No wonder, therefore, that a whole series of medical men has striven to devise methods of rendering this part accessible to the eye. This object may be attained in two fundamentally different ways. The observer may either introduce a dilating instrument into the particular region to be examined and then view the exposed parts directly or indirectly (by means of the laryngeal mirror), or manipulations causing the lamina of the cricoid cartilage to move away from the posterior wall of the hypopharynx may be so directed that an introduction of instruments in the laryngeal part of the pharynx is avoided during the inspection. As will be shown later the latter way is the right one.

To the first group appertain nearly all the methods hitherto recommended and employed. In order to review them they may be divided into two classes, one based on the use of tubular specula and another in which valvular specula with dilating branches moving either in the transverse or antero-posterior plane are employed. Under the name of œsophagoscope Bevan in 1868 and Waldenburg[5] in 1870 recommended a short tube to be introduced into the laryngeal part of the pharynx and the uppermost part of the œsophagus. The mucous membrane presenting itself through the tube might then be inspected indirectly by means of the laryngeal mirror. Waldenburg showed that a pressure diverticulum could be diagnosed in this way, as he was able to introduce his instrument alternately into the diverticulum filled with ingesta and into the entrance of the gullet. Morell Mackenzie, who diagnosed by means of his œsophagoscopic skeleton tube[6] the presence of a carcinomatous ulcer and in another case a benign polypus a little below the cricoid cartilage, and also removed by means of the same instrument pieces of tissue for microscopical examination and extracted foreign bodies from the œsophagus,[7] must undoubtedly also have been able to inspect the lower laryngeal part of the pharynx. In 1893 Löwe[8] published the description of an instrument for inspection of the œsophagus (as also of the

patient, that during a retching movement the larynx suddenly retired somewhat from the vertebral column, so that he was able to look from four to five centimetres downwards into the gaping pyriform recesses and entrance of the gullet. This observation von Eicken could repeat in the same patient, and less completely in two others, when he irritated the posterior wall of the pharynx by means of the laryngeal mirror. In the great majority of patients, however, these attempts did not succeed, and therefore von Eicken began to search for a method which should enable him to inspect this region in all cases. At last he devised the following procedure, which he denominates hypopharyngoscopy. After careful cocainisation of the fauces, the root of the tongue, and the larynx, the patient is seated on a high chair, whilst the surgeon kneels down before him. This position is chosen because the patient must incline his head forward in order to release the muscles on the anterior side of the neck; these muscles thereby become unable to contract and so prevent the surgeon from pulling the larynx forward away from the vertebral column. But at the same time the inclined position of the head of the patient obliges the surgeon to kneel down as it becomes necessary for him to look from below upwards at the laryngeal mirror placed in the usual way against the soft palate. Next, a strongly built laryngeal probe of somewhat greater dimensions than the ordinary ones is introduced through the rima glottidis down into the subglottic space, and the larynx is pulled slowly in the direction forwards and upwards, the proximal straight part of the probe resting against the upper teeth, so that the probe acts as a lever. In the laryngeal mirror it may then be observed that[23] "the larynx is drawn one and a half to two centimetres away from the posterior wall of the pharynx, the two pyriform recesses join into a common cavity, and in the depth the entrance of the gullet is seen closed by the constrictor pharyngis inferior. Often a facetting of the lamina of the cricoid cartilage is visible through the mucous membrane, laterally to a median prominence. Occasionally it is also observed how that part of the mucous membrane that is loosely extended over the lamina of the cricoid cartilage and its muscles becomes drawn out to a fold stretching backwards, when the larynx is lifted away from the posterior wall of the pharynx; when the pull becomes stronger the fold disengages itself from the posterior wall of the pharynx and sinks back in a level with the rest of the mucous membrane on the lamina of the cricoid cartilage." To this description I may add that I have not rarely seen in my patients the gullet open up during vocalisation and thus have been given an opportunity of inspecting the uppermost part of that canal.

It is obvious that this method is of great importance for the diagnosis of affections of the lower laryngeal part of the pharynx and of the adjoining uppermost part of the gullet; it is not necessary to rest content after inspecting the alterations of the mucous membrane; it is also possible to use the probe and to excise tissue for examination or to remove foreign bodies under control of the eye. In these cases the patient himself or an assistant must pull the larynx forward, whilst the operator holds the laryngeal mirror with his left hand and manipulates the requisite instrument with the right. Von Elchen has thus verified the diagnosis of cancer of the region in question by an excision of diseased tissue in a case in which Killian's tube-spatula failed to give sufficient information. At the ear and throat clinic of the Kommune Hospital we have likewise had occasion to learn the value of the method in a case which at first presented considerable diagnostical difficulties. The patient was a nurse at the hospital, aged 61 years, who had formerly suffered from severe attacks of biliary colic and uterine hæmorrhage (fibromata uteri). About 20 years ago she had for some months the sensation of not being able to swallow solid food. This sensation then passed away and left the patient with no difficulty in deglutition, until suddenly one day about ten years ago she was nearly suffocated whilst swallowing a morsel of meat. A house surgeon tried to introduce a bougie into the gullet, but failed to do so, and whilst he hurried away to prepare for tracheotomy, the patient was seized with a violent attack of coughing and expelled the offending morsel of meat. During the ensuing ten years the patient has been able to swallow all sorts of food without any difficulty whatever, until her present disease began about six months ago. At this time she began to suffer from attacks of darting pain referred to the region of the hyoid bone and irradiating into the shoulders and the right ear; the pain occurred both independently of and during deglutition. Setting aside the odynphagia her deglutition was quite normal; she was, and is, able to swallow just as big morsels as usually and she has increased in weight from 66½ to 69 kilogrammes during the six months of her disease. Soft indiarubber œsophagus tubes stopped about 16 centimetres from the teeth, a Stille's bougie with its olive-shaped metal knob of 12 millimetres diameter passed after some delay in the region of the hyoid; ordinary conical gum-elastic bougies (up to 12 millimetres in diameter) were easily introduced into the stomach. On Roentgen ray examination an abnormal shadow was visible behind the thyroid cartilage, which awakened suspicion of a tumour in this region; abnormal shadows were also present at the hilus of the lungs, which may have been due to old tuberculosis or metastases in the glands of the hilus. Laryngoscopy, however, showed the upper laryngeal part of the pharynx, the larynx itself, and what might be seen of the trachea to be absolutely normal; stethoscopy was normal and no enlarged glands were palpable. By direct superior tracheoscopy with Killian's tube-spatula a certain bulging of the posterior wall of the trachea was detected just below the cricoid cartilage, but this bulging was not sufficiently pronounced to be declared undoubtedly abnormal; an attempt at œsophagoscopy provoked severe pain and was at once abandoned, as there was strong suspicion of pathological alterations in the lower laryngeal part of the pharynx; of what nature these might be all the preceding examinations had failed to show. Only hypopharyngoscopy by von Eicken's method proved conclusive, showing as it did at the first glance at the mirror an ulceration with greyish-white base situated at the lower border of the cricoid. Our ordinary laryngeal instruments for excision proved too short, but after we had had the universal larynx forceps of Fränkel-Pfau made longer we succeeded in removing from the posterior wall of the pharynx at the very entrance to the gullet a piece of tissue, which upon being submitted to the pathologist turned out to be a papillomatous surface-epithelium carcinoma.

The use of the hypopharyngoscope is *indicated* in cases of benign and malignant new growths, cicatricial and other strictures, or tuberculous, syphilitic, and other rarer ulcerations in the cricoid part of the pharynx. But not only in these cases may we expect to get help in diagnosis and treatment from the new method; in all probability it will also become more easy to get at pressure diverticula, partly because we shall be able to diagnose the diverticulum in its early stages and partly because in large diverticula we may hope to find the very often dislocated entrance to the gullet by means of the laryngeal mirror. For my own part, I think hypopharyngoscopy should always precede an œsophagoscopy when an inspection of the gullet is desired in an individual who has not formerly been examined with the œsophagoscopic tube. Even though in the great majority of cases nothing abnormal will be found in the hypopharynx, the adoption of the proposed measure will help to guard against disagreeable surprises (cf. the case of Czerny, quoted above).

As for inconveniences connected with the method, they might perhaps *a priori* be thought not insignificant. The idea of introducing a thick probe through the rima glottidis and pulling the larynx forwards by means of it may appear a little brutal to those unaccustomed to laryngology. Having now used the method in about 20 cases I am, however, able to state that none of the patients thought the method very disagreeable, let alone painful; they only perceive a pull in the throat, nothing more. What annoys them most is the cocainisation itself, and a thorough application of cocaine is a *sine quâ non*.

But is it not possible that the pressure exerted on the mucous membrane in the interior of the larynx may have some detrimental influence on the epithelium thereof? At first I rolled some absorbent cotton round the knob of the probe and applied thereto a few drops of a 20 per cent. solution of cocaine, as I have seen done in Freiburg, in order to diminish the sensation of the pressure exerted by the probe. Once or twice I have seen a couple of days later a whitish patch surrounded by a red halo on the anterior surface of the subglottic space, an alteration of the mucous membrane, which disappeared in one or two days; nor is it to be wondered at that an intimate contact of a mucous membrane with a 20 per cent. solution of cocaine should

observed left ventricle was also dilated. The muscle showed brown
loosely ophy. The greater portion of the pulmonary semilunar
its r ves was missing; only their irregular and thickened bases
wards mained. Attached to one of these was a large mass
of the yellow friable vegetation measuring one and a half inches
deep n length and one-third of an inch across, which extended
fibr along the pulmonary artery. This mass was firm at the
c centre but more friable outside. There were several small
vegetations in addition to this. No inflammatory change
was present in any other of the cardiac valves but very slight
atheromatous patches were detected in the mitral and aortic
valves. The tricuspid valves and the arteries were perfectly
normal. There were tough pleural adhesions over the apices of both lungs. At the left base was a large area of solid lung, firm, rigid, and moulded to the chest walls and diaphragm; it did not appear to be shrunken and on incision it was tough and gritty to touch, of a white colour, and sharply delimited from the adjacent air-containing lung. The pleura over this area was thickened but smooth. Several similar patches were found in both lobes of the left lung and the lower right lobe, but these were much smaller. From their arrangement they appeared to be old infarcts, which had undergone organisation and calcification; this view was confirmed by the microscope. No recent infarcts were seen. The pulmonary tissue was œdematous and congested on both sides. The liver was considerably enlarged and showed advanced nutmeg change. The spleen was very large and weighed 17 ounces; its capsule was smooth and tense; on section the organ was firm and fleshy, but it contained no infarcts. The kidneys showed cloudy swelling and congestion only. The right ovary contained a corpus luteum; the uterus was enlarged and its mucous membrane intact save where the placenta had been attached. No sign of sepsis was present. In the upper part of the cervix uteri was an old superficial scar in the mucous membrane, about half an inch in length, running vertically. It had the appearance of having been produced by an instrument. (At the miscarriage in hospital no instrument was used and the finger was not introduced into the cervix or even into the vagina.) On microscopical examination of the fibrinous vegetation found on the pulmonary valve large numbers of micrococci were visible; these took stains such as hæmatoxylin or neutral red quite readily, but did not retain the colour when stained by Gram's method. They did not show any particular arrangement, nor were they grouped as diplococci. No pure culture was obtained. No organisms were found in the spleen or in the lungs.

Remarks.—Pulmonary incompetence is the rarest of the cardiac valvular lesions. In Dr. Newton Pitt's article[1] in Vol. VI. of Allbutt's "System of Medicine," only 99 verified cases are mentioned. Of these only 57 were caused by infective endocarditis. The case which we now report is specially noteworthy, because in it the pulmonary valves were alone affected. The diagnosis of the lesion presented some difficulty, as one would expect when it is remembered that half the recorded cases have not been diagnosed before death. The symptoms, such as pallor, dizziness, &c., combined with a double murmur heard down the left side of the sternum, seemed at first to point to aortic regurgitation; but the site of maximum audibility, the dulness and thrill in the first left space, the fact that a distinct second sound was heard both at the aortic area and at the extreme left border of the heart, and the pulmonary infarcts which Dr. Lees inferred from the circumscribed patches of dulness which he detected on percussion, combined to make a symptom-complex indicating pulmonary endocarditis and incompetence. This diagnosis was therefore definitely made and was confirmed by the evidence of cardiac back-working as the disease took its course. The triple rhythm audible down the left side of the sternum may have been due to slight ventricular asynchronism, but in view of the fact discovered post mortem that the pulmonary valves were destroyed and that what little competence remained was entirely due to the large walnut-sized vegetation in the artery lumen, it seems possible that the triple rhythm may have been due to this mass becoming impacted in the artery as the blood flowed back. The localised patch of œdema situated over the lower part of the sternum, together with the increased cardiac dulness, led at first to some doubt as to whether the unusually rough sounds at the base were not pericardial in origin, and it must be remembered that the necropsy revealed the presence of some lymph over the auricles and some turbid fluid in the pericardium. The spleen was enlarged and was of a rather lighter colour than usual. The increase in size and the general appearance of the organ were hardly to be explained by the cardiac condition alone, but pointed to some kind of general infection. The casts which were found in the urine on the patient's admission to hospital were not explained by any lesion found in the kidneys at the necropsy, though cloudy swelling and very slight fatty degeneration were detected microscopically.

Infective endocarditis of the pulmonary valves is most frequently of gonorrhœal origin. In our case the fact of pregnancy in an unmarried girl, with the scar in the uterine cervix suggestive of an attempt at abortion, render a gonorrhœal infection possible, although the bacteriological report was not sufficiently positive for us to say anything definitely.

CASE 2. *An aortic aneurysm which ruptured into the pulmonary artery and caused regurgitation.*—The patient, a man, aged 39 years, was admitted into St. Mary's Hospital on Sept. 8th, 1905, complaining of pains in the left side of the chest, accompanied by shortness of breath, giddiness, palpitation, and attacks of faintness. The history was that he had had a pain in the cardiac region for two or three months. He had before that been working harder than usual at his work in order to gain promotion, and just previously to the onset of his illness he had taken part in a "tug-of-war," in which he thought he had strained himself; a cough had troubled him for a week before admission. No history of syphilis could be elicited. He had been a moderate drinker but had smoked about half an ounce of tobacco daily for many years; to this he attributed some attacks of dizziness which occasionally troubled him.

On admission the patient was found to be a tall, thin, and pale man, the upper part of whose body shook with each heart-beat, while the carotids pulsated visibly. He said that he felt the cardiac pulsations and that they caused him some distress. There was no œdema of the legs. The pulse was 100, irregular in force but regular in frequency, collapsing, with a full and short wave of dicrotic character. The artery wall was slightly thickened. The radial pulses were equal. The heart's impulse was diffuse in the fourth, fifth, and sixth intercostal spaces on the left side, both outside and within the nipple line. A very marked systolic thrill could be felt to the left of the sternum in the third and fourth spaces. The deep cardiac dulness extended two fingerbreadths outside the vertical nipple line in the sixth space. On auscultation in the third left space at the border of the sternum a long, very loud, and practically continuous murmur was heard; this waxed and waned in intensity, the maximum being during systole, the minimum in diastole. In the second left space the diastolic element was separated from the systolic and both were softer and shorter. The murmurs at their loudest were startling in their intensity. At the apex a long systolic murmur, a faint second sound, and a short diastolic murmur were heard. At the aortic area both murmurs could be heard but they were not so loud. Capillary pulsation was obtainable. A cough was present, but no lesion was detected in the lungs. The stomach was dilated outwards, whilst the liver reached just below the costal margin in the vertical nipple line. The left eye was sightless from old injury and deviated outwards. The urine was normal. There were no tracheal tugging and no visible pulsation or abnormal dulness at the cardiac base. The condition remained about the same for a few weeks, but after a month's rest in bed in the hospital the pain in the chest was even worse than when he came in. He was then unable to sleep on his right side and the pain was noticed to be increased when he took a deep breath. Signs of back pressure began to be more noticeable on Oct. 4th, when the liver reached three fingerbreadths below the costal margin in the nipple line. On Oct. 9th the left side of the heart was dilated out as far as three fingerbreadths beyond the nipple line in the sixth space, whilst the liver then reached down as low as the umbilicus. The dyspnœa was more obvious and the patient complained of pain over the hepatic region. At this time a second sound was noted as being heard at the aortic area, whilst slight dulness was found over and on either side of the sternum in the first space, probably due to dilated aorta. A little later he complained of waking up suddenly during the night in a fright owing to the disquieting sensations in his chest. His cough became worse and on the 14th some hæmoptysis occurred. An ice-bag applied to the præcordial region somewhat relieved the distress, but the general condition became worse, the dyspnœa increased, appetite was lost, and he became depressed in spirits. On one occasion a small venesection was performed and seemed to relieve him for a time, but as a rule it was necessary to give him morphine and atropine hypodermically in order to procure rest. On the 17th he complained of the sensation of a lump in his throat and vomited once or twice. The backworking of the heart became more extreme, the right heart became dilated, whilst œdema of the legs and tenderness and pain in the calves were prominent symptoms. Orthopnœa developed and a bed-table was found necessary on the 19th. Death occurred on the 22nd.

Post mortem the pericardial cavity was found to contain about three ounces of clear fluid. The right heart was considerably dilated and hypertrophied. The tricuspid orifice admitted three fingers. The posterior cusps of the pulmonary valves were adherent to the artery wall. Just above the cusps were two minute apertures with rounded and thickened margins, opening into an aortic aneurysm. A little above these was a similar but larger and evidently more recent opening about half an inch in diameter. The left ventricle was slightly dilated and somewhat hypertrophied. In the anterior wall of the aorta, just beyond the level of the valve cusps, was a saccular dilatation which measured one and a quarter by one and a half inches by three-quarters of an inch. The wall of the sac was thin and smooth on the inner surface and no deposit of blood clot was found. Old tough adhesions were found over the base of the right lung. There were marked pulmonary congestion and œdema, and portions taken from the bases sank in water. Slight bronchitis and emphysema were noticed. The liver was enlarged, congested, and firm in consistence; the spleen was enlarged and congested. The kidney capsules were somewhat adherent and the cortex was diminished and pale. The renal vessels showed atheromatous changes.

Remarks.—Amongst the 99 cases mentioned above, 14 instances are included in which the incompetence was due to an aortic aneurysm rupturing into the pulmonary artery and causing the valves to adhere to the walls of the artery. The lesion is said not to be very uncommon, and several specimens showing the same condition are to be seen in the various hospital museums. The diagnosis was made difficult by the accompanying aortic regurgitation. The presence of an aneurysm was regarded as certain, but the extraordinary nature of the sounds, both as to intensity and continuity, made those who saw the case confident that there was something in addition to aortic incompetence and this lesion. The suggestion was discussed as to whether the aneurysm had broken through into the pulmonary artery, but no certain conclusion was arrived at on this point. During life the pulmonary incompetence was not differentiated from the aortic regurgitation. The history of strain in this case is interesting and it may well be that the older perforations into the pulmonary artery were caused by the sudden exertion in the tug-of-war. He said that at the time in question he felt curious painful sensations, the like of which he had never experienced before; the pains were referred to the abdomen. Up to this time he had been in fairly good health, though family troubles had worried him. The rapid increase in the severity of the symptoms towards the end was no doubt partly due to the more recent perforation which was found. The part which excessive smoking plays in promoting arterial degeneration is not sufficiently understood for us to be able to say anything as to its influence in this case, but the fact remains that the patient was a heavy smoker.

For comparison with Case 2 we subjoin an abstract of the notes of another case of aortic aneurysm which ruptured into the pulmonary artery under the care of Dr. Lees in 1901.

The patient was admitted to hospital, under the care of Dr. Lees, on Feb. 8th, 1901, complaining of shortness of breath. History of present condition.—March, 1900: shortness of breath first noticed. June, 1900: left off work; legs and abdomen swelled. September, 1900: an inmate of Marylebone Infirmary, where the abdomen was tapped and the right chest explored. Personal history.—Previously healthy; a heavy drinker (up to a pint of rum daily); smoked half an ounce of tobacco weekly. Conditions on admission:—Cyanosed and orthopnœic; cold extremities; temperature 97·5° F. Heart: Pulsation over whole of præcordia and slight epigastric pulsation; a marked and nearly continuous thrill felt from the vertical nipple line to two fingerbreadths beyond the right margin of the sternum, and from the second to the fifth space on the left side, and the second to the fourth space on the right side; maximum in the third left space close to the sternum. Deep cardiac dulness: left, two fingerbreadths external to the vertical nipple line; right, three fingerbreadths external to the right margin of the sternum. On auscultation at the mitral area a first sound, a systolic murmur, and a second sound (murmur heard in the axilla). From one fingerbreadth internal to the vertical nipple line to the right is heard a continuous roaring murmur (something like the noise made by a train passing over a bridge); maximum in third space close to the sternum. A short second sound can be heard and that part of murmur which follows this differs in character from that which precedes it. A rough scratching sound of cardiac rhythm heard over the tricuspid area. Signs of fluid in the lower right chest. Liver enlarged downwards. Feb. 9th: Cyanosis disappeared; deep cardiac dulness one and a half fingerbreadths external to the right margin of the sternum (after leeches); systolic impulse in the third left space. The murmur starts with systole and is almost continuous till the next beat. 13th: Aortic and pulmonary second sounds noted as being distinctly heard in midst of roaring murmur. 18th: Abdomen tapped, 120 ounces withdrawn; right side of chest aspirated, 14 ounces of fluid withdrawn. 22nd: Troubled by cough; 108 ounces withdrawn by tapping abdomen; slight œdema of the lower part of the back; swelling of the left leg increased. 27th: Thrill more localised, conducted out towards the left, and more marked on expiration. March 2nd: Specific gravity of urine, 1004; faint trace of albumin. 6th: Some vomiting. 7th: Vomiting and diarrhœa. 8th: Murmur not so continuous as previously. 9th: Vomited. 13th: Coffee-ground vomit. 16th: Six ounces of fluid drawn from right chest 18th: Vomited; no cyanosis. 19th: Much better. 20th: Cyanosed; anorexia; venous pulsation marked in the neck. 21st: Died; the body temperature was subnormal for many days before death, usually about 96°. *Post-mortem notes.*—Fluid in both pleuræ. Four ounces of fluid in pericardium. Old and recent pericarditis. Heart 22 ounces, both ventricles dilated and hypertrophied. There was a small sacculated aneurysm of the aorta arising just above the right semilunar valve. This communicated by an oval opening half an inch in length with the pulmonary artery just by the posterior pulmonary valve, which was adherent to the wall of the vessel. There were recent atheromatous ulcers of the aorta. Several pints of ascitic fluid were present. Old peritonitis with adhesions over the spleen and liver. Liver, 44 ounces, small and firm, nutmeg appearance. Kidneys, four ounces each; cortex good. Spleen, four ounces, small and firm.

ACUTE AND CHRONIC APPENDICULAR PAIN; MEDICAL AND SURGICAL TREATMENT: A CRITICAL ESSAY.

By SAINT-RENÉ BONNET, M.D. PARIS, L.R.C.P. LOND., M.R.C.S. ENG.,
CONSULTING PHYSICIAN AT CHATEL-GUYON-LES-BAINS, AUVERGNE, FRANCE.

THERE is a marked tendency at the present time, in French medical circles, at least, to abandon surgical treatment in cases of acute appendicitis and chronic appendicular pain, and I propose in this paper briefly to review this question and will first consider—

Causes which have induced medical men to restrict surgical treatment.—From the very outset, when operations were performed for recurring attacks of pain in the region of the vermiform appendix, the *following* facts were noted: 1. In the course of operations the appendix was often found to be quite normal or only slightly involved. It seemed therefore difficult to consider it the cause of the trouble which had necessitated the operation. 2. Sometimes when the appendix, whether healthy or not, had been removed, chronic pain persisted just as before; even fresh attacks similar to that of relapsing appendicitis occurred. 3. In spite of the general tendency to resort to surgical treatment there were many cases where the symptoms seemed to point to a fatal termination, but in which, however, recovery was obtained without surgical interference. 4. These strictly medical cures assumed greater importance when the results of operating during the acute period of the affection, with all the risks it entailed, became better known. These facts at first puzzled both physicians and surgeons; but most of them were explained when careful studies of the morbid syndrome, now so frequently met with and which is called muco-membranous entero-colitis, were made, the intestinal symptoms of which may be thus tabulated.

(*a*) *In well-characterised muco-membranous entero-colitis.*—*Chronic constipation*, with or without occasional attacks of diarrhœa; *diarrhœa*, which may become chronic, and is observed in the place of chronic constipation more than is generally supposed; *spasmodic contractions* of the large bowel which alternate or co-exist with dilatation of one or more of its portions; *persistent pain* which becomes intense during the acute periods of the affection; *passage of mucus and casts* with occasional intestinal *hæmorrhages*, and in some cases abundant evacuations of *intestinal gravel.*

Now there are two important signs which must always be kept in mind, for they are practically never absent. Firstly, when paroxysms of muco-membranous entero-colitis are localised or predominate in the right iliac fossa at, and around, McBurney's point, they present symptoms which may resemble exactly those of an acute attack of appendicitis, and when there are no acute paroxysms of the disease there may be persistent pain which simulates that of chronic appendicitis. As in true appendicitis, the pain, whether acute or chronic, is of a shooting, stabbing, or colicky character, or is replaced by a more or less marked sensitiveness in the right iliac region. This pain is increased by movement. Secondly, experience teaches that when in the course of supposed acute appendicitis or of chronic appendicular pain mucous casts are passed in the stools the physician is bound to feel entirely reassured as to the nature of the trouble and is enabled to give a good prognosis. I have verified this many times since I began to practise at Chatel-Guyon in 1899. The same holds good when a history is obtained of the passing of mucous casts, even a very long time previous to the appendicular pain.

(*b*) *In latent forms of muco-membranous entero-colitis, in which false membranes are absent.*—There are latent forms of muco-membranous entero-colitis in which mucous casts which have been considered as the main intestinal symptom of the affection are not found. Some authors even consider one of these latent varieties as a special disease, which they call *spasmodic constipation.* It is mainly characterised by intestinal contractions and chronic constipation. Spasmodic constipation I consider to be a latent form of muco-membranous entero-colitis. I think that when the system has been attacked by the morbid process which gives rise to the syndrome muco-membranous entero-colitis it may react in different ways. Sometimes all the usual symptoms are present; sometimes one or more of them are absent. In fact, observation often shows that even after years of alleged spasmodic constipation mucous casts do appear and lead to the diagnosis of the real nature of the disease. Latent forms of the affection are more frequent than is generally thought and may be associated with acute paroxysms or chronic pain in the right iliac region. It is the careful study of the character of the pain and intestinal spasm in the acute or chronic condition in such latent forms that will make the physician feel reassured.

When an acute paroxysm comes one fact stands out above all others, and that is, that the pain does not possess the peritoneal characteristics. It does not spread to the whole abdomen as it does in peritonitis, in which the tenderness of the whole abdomen is so acute that the patient cannot even bear the weight of the bed-clothes; on the contrary, the pain, although it may present its maximum intensity at McBurney's point, follows also the ascending part of the colon and diminishes gradually along its transverse segment. There may be a certain degree of contraction of the abdomen, especially in patients of a nervous temperament, but it is never so marked as to prevent palpation, which, if lightly performed, will show that there are contraction of the cæcum and pain both over the cæcum and the ascending colon; also, that one or more portions of the large intestine are the seat of increased sensibility or of spasm. I never neglect this methodical and systematic examination of the cæcum and colon and I have come to the conclusion that the information supplied by palpation thus applied is of as great importance as the presence of the mucous casts themselves. When there is no acute paroxysm but simply chronic pain in the region of McBurney's point palpation becomes much easier and brings out very plainly the painful and spasmodic condition of the large bowel.

Thanks to our actual knowledge of muco-membranous entero-colitis we see now why medical instead of surgical treatment is quite rightly applied to the numerous patients suffering from appendicular pain in the course of this affection. We understand why so many cases of acute or chronic appendicular pain have been ameliorated or cured without operation, and this in spite of the late general belief. We know that it is especially in this class of patients that surgeons have found the appendix to be either normal or only very slightly affected, and that acute or chronic pain in the appendicular region persisted after the removal of the appendix.

I must lay stress upon another point which I consider is of great practical importance. The appendices which have been removed after acute paroxysms or chronic pain in the course of muco-membranous entero-colitis and which have been found affected present, whatever their other lesions may be, a special degree of resistance. Their walls are thickened and they may be surrounded by protective peritoneal adhesions. The slow and continuous irritation of the morbid process in muco-membranous entero-colitis does not destroy altogether the feeble vitality of the appendix. It does not prevent it from forming cicatricial tissue which, together with the peritoneal adhesions, forms a substantial barrier to fresh and more severe causes of infection. In these circumstances, should some other cause of appendicitis supervene, although it may give rise to acute or chronic attacks, the patient stands a much better chance of avoiding generalisation of the infection to the whole peritoneum.

There is not the slightest doubt that there are cases in which complete recovery has been obtained by medical means alone in patients suffering from either acute appendicitis or chronic appendicular pain and who are quite free from muco-membranous entero-colitis. Every year I have the opportunity of attending some of these patients who come to Chatel-Guyon to improve the state of their digestive organs and thus reduce their liability to further attacks. (See below, Case 1.) I can quite understand, therefore, that when the far from satisfactory results obtained by operation during the acute period of appendicitis became known physicians preferred to resort to medical treatment alone. In the majority of cases the patient is brought safely through the dangerous stage of the affection and the acute period with all its dangers once passed the patient nearly always considers that since medical means succeeded so well one cannot do better than continue with them. On the other hand, the physician may feel that his responsibility will be very great indeed if the patient having safely got through this dangerous appendicular crisis succumbs to an operation even made "*à froid.*" And so both patient and medical man come to the conclusion to have recourse to a compromise, which from a human point of view may be easily understood. The result is that an operation is put off until the patient's life is greatly endangered by a new attack or until appendicular pain has become so chronic as to constitute a real infirmity. In short, cases of acute appendicitis, having no connexion with muco-membranous entero-colitis, are operated upon less frequently because cures have been obtained (sometimes quite unexpectedly) by medical treatment and because the risk of a fatal termination, even after the operation "*à froid*," cannot be entirely suppressed.

To sum up the first part of these facts, we see that there have been good reasons for the restriction of the surgical treatment in cases of appendicular pain, and the general tendency to resort more frequently to medical methods seems to me to be quite justified. On the other hand, however legitimate this opinion may be, one must not neglect the advantages of surgical treatment in special cases; these I shall proceed to consider.

Should the modern tendency to resort to medical treatment alone in cases of acute or chronic appendicular pain spread too widely it might lead to the neglect of useful or imperative surgical interference.

(*a*) *Appendicular pain occurring in patients who do not present any symptom of muco-membranous entero-colitis.*—I readily admit that in many patients of this class the acute period of appendicitis is ameliorated by using medical means alone; even full recovery may be observed in some instances. (See Case 1.) Physicians, however, though rightly remembering the reported cases in acute or chronic cases of appendicitis, should never forget the many unknown clinical points they have to face when called upon to express an opinion—i.e., anatomical condition of the appendix, its pathological state, the real cause and the degree of virulence of the affection, and the resistance of which the appendix is capable. Experience shows also that in acute or chronic appendicitis a fatal termination sometimes very rapidly occurs. These very serious facts should always be borne in mind when the comparatively small risks of an operation "*à froid*" are being discussed; they ought to weigh heavily in the balance when the time has come to make a decision. The question is so much more difficult to solve as there is no certain symptom to guide us as to the future of the affection and thus every acute case has to be carefully studied on its own merits. Personally, I must say, that in spite of the favourable cases I come across every year the possibility of an unexpected acute attack coming on quite suddenly and ending fatally has always induced me to suggest an operation "*à froid*" when the condition of the patient after a few months' medical treatment has undergone no marked improvement.

(*b*) *In appendicular pain occurring in patients suffering from muco-membranous entero-colitis.*—I do not think it is possible to get rid of muco-membranous entero-colitis by simply removing the appendix, even when the latter is diseased, and I am confirmed in this opinion by the study of a large number of cases. Medical treatment, therefore, seems to me to be the most important in such cases. But, on the other hand, I do not believe that surgical treatment should be entirely abandoned, as is the general tendency in cases of muco-membranous entero-colitis. There are at least two conditions in which surgical interference may be indicated.

1. In conjunction with the cæcum and the ascending colon, the appendix, even without any change in its structure, plays a part in paroxysmal or chronic pain limited to the right iliac fossa in cases of muco-membranous entero-colitis. Now there are circumstances in which, either because of the general state of the nervous system or for some other reason, the appendix, influenced more especially by the existence of muco-membranous entero-colitis, gives rise to intense secondary reflexes, either general or local. These reflexes may render the patient a confirmed invalid. (See Case 2.) This condition specially presents the very serious inconvenience of neutralising all the purely medical means used against muco-membranous entero-colitis. In cases such as this, when the reflexes to which I have just alluded persist for more than 18 months or two years without improvement, I consider that an operation for removal of the appendix must be seriously thought of, even if the appendix were to be found normal. I must say, however, that such cases are not frequent. In Case 2, which is related farther on, operation did not cure the muco-membranous entero-colitis but it stopped the secondary reflexes which, taking their origin in the appendix, practically crippled the patient. Subsequently he was able to get the full benefit from medical treatment, which alone is able to cope with the affection itself.

2. There are chronic cases of appendicular pain in which the condition of the appendix already influenced by muco-membranous entero-colitis may still be complicated by added or supervening causes, such as an exaggerated length of the appendix, appendicular calculi, or the presence of pathogenic micro-organisms. Of course, thorough diagnosis is very difficult in these circumstances, and although they are not frequent still they do exist and must be taken into consideration, and when once their existence has been suspected the removal of the appendix should be advised. But should surgical interference be delayed for any reason in such complicated cases I firmly believe that the presence of muco-membranous entero-colitis is still sufficient to reassure physicians as to the immediate prognosis of acute paroxysms, and this thanks to the already mentioned special resistance of the appendix in this chronic affection.

Thus, in spite of the marked improvement in the study of the indications for medical treatment in acute or chronic appendicular pain, I think it would be a great mistake to approve without reserve the general tendency if it were to lead us systematically to ignore the help given by surgery.

I append a clinical account of three cases in illustration of this paper.

CASE 1. *A typical case of chronic appendicitis, without muco-membranous entero-colitis, cured by medical treatment alone.*—The patient, a man, aged 36 years, had led a very active life. His first season at Chatel-Guyon was in 1903. Until 1890—i.e., until the age of 23 years—he had always enjoyed the best of health. His digestive organs were in perfect order, the functions of the stomach were quite normal, the large intestine was normal in muscular tone and had never been painful, it acted regularly twice a day, and the stools were normal. In 1890, one morning, whilst the patient was still in bed and just going to get up, he felt all at once a most intense and agonising pain like the stab of a knife at McBurney's point. Constipation set in immediately and was complete during three days. The whole abdomen rapidly became very painful and the patient could not even bear the weight of the bedclothes. Vomiting came on but was not frequently repeated. The temperature rose but never became very high. The attack lasted altogether 15 days. The patient was then able to get up and gradually resumed his ordinary occupations. Since 1890 the patient had to watch carefully the functions of his stomach, which were very easily upset. There were a semi-chronic state of constipation and a marked constant pain at McBurney's point; the pain was increased by over-eating, by the act of walking, and especially by railway travelling. In 1899 he had a second very severe attack of appendicitis. Surgical intervention was seriously thought of but was put off for the moment. He recovered from this fresh attack but returned to his previous bad condition. In 1903 he had his first season at Chatel-Guyon. On examination of the large intestine no spasmodic condition was found and none of its segments were painful. McBurney's point alone was very tender, as it had always been since 1890. There were neither mucus, nor mucous casts, nor gravel in the stools, but the fæces were very hard and nodular. The stomach was dilated, but both the liver and the kidneys were normal. Appendicular pain was slightly increased during the first days of the cure, but it did not last long and there was soon a marked improvement of the digestive functions. A short time after his departure from Chatel-Guyon appendicular pain, which had notably diminished during the latter period of the cure, disappeared entirely and the patient was able to get through a good deal of work without the slightest inconvenience. He never resorted to the help of any sort of abdominal belt or support and he was only very careful in his regimen. The large bowel, once again, as previously to the year 1890, began to act regularly twice a day. In 1904, his second season at Chatel-Guyon, I found nothing abnormal on examining him. The stomach was neither dilated nor painful; the bowel was normal on palpation and there was no pain at McBurney's point. The patient went through his second cure very carefully. He never came back to Chatel-Guyon and I am informed that he has since been enjoying very good health.

CASE 2. *A case of muco-membranous entero-colitis, in the course of which painful secondary reflexes arising from the appendix quite disabled the patient and necessitated surgical intervention.*—The patient, a man, aged 31 years, spent his first season at Chatel-Guyon in 1904. He had always been of a very nervous and impressionable temperament, but up to the age of 26 years he had never suffered from any disease. At the age of 26 years he contracted a rather severe attack of bronchitis which lasted a month, but he got quite well again. In short, until the age of 27 years the patient had a very good appetite, his bowels acted regularly, his stools were normal, and his sleep was perfect. At the age of 27 years constipation set in for the first time—two or three days passed sometimes without any stools; the fæces became hard and covered with mucus. At the same time digestion was impaired, with a sense of fulness in the epigastric region after meals. He had also, now and then, colicky pain in the region of the transverse colon, with diarrhœa and mucous casts. For the next three years he had no treatment. In March, 1903 (at the age of 30 years), he consulted his family physician, since the state of his health had become worse. After having been constipated for several days he passed a motion consisting of very hard matter and soon after a very acute pain in the right iliac fossa came on, lasting 48 hours. The temperature rose to between 38° and 38·5° C.; constipation was complete and there was vomiting. During the paroxysm pain was localised to the right iliac fossa. The crisis disappeared gradually and it was only after complete rest in bed for a period of eight days that the patient felt really better. Since this attack mucous casts were passed in greater quantity in the stools. In October, 1903, a second painful crisis came on, which lasted two or three days, and, as in the former, was limited to the right iliac fossa. In March, 1904, a third attack of a violent character, also localised to the right iliac fossa, took place, after which the patient went to Paris for a consultation. The removal of the appendix was strongly opposed. He was told to follow a strict regimen and to have the skin of the affected region cauterised every week for a month with the thermo-cautery. From March to June, 1904, he had a series of painful attacks which predominated in the right iliac fossa, but extended also to the transverse colon. In June, 1904, he spent his first season at Chatel-Guyon, where I then saw the patient for the first time. I found that he was exceedingly excitable and impressionable; the stomach was little affected, but the large intestine was contracted and tender in the region of the ascending colon and sigmoid flexure. Pain existed over the flexures of the colon and more particularly at McBurney's point. The right kidney was slightly displaced and gave rise to rather sharp shooting pains, extending from the right lumbar region to the right testicle. The left lobe of the liver was tender on pressure but the rest of the organ seemed normal and in its right position. The patient never had any hepatic colic. During the time of his "cure" he had a whole series of exceedingly painful attacks localised around McBurney's point, one paroxysm coming on before the other was finished. Pain never presented the peritoneal character. On arrival at Chatel-Guyon (we must remember this important fact) pain in the peri-appendicular region was so intense as to render the patient practically helpless. He could hardly walk a few steps, and the slightest movement was enough to bring on a paroxysm. There were several acute attacks of pain in the right iliac fossa; constipation was still more obstinate and mucous casts were passed both during paroxysms and in the intervals. As there had been no improvement in the state of the patient, who had been reduced to a chronic invalid by the persistent nature of the appendicular pain, he underwent operation and the appendix was removed on May 17th, 1905. The latter was found to be small, hard, quite free from adhesions, and containing nothing in its cavity. We see, therefore, that the patient's life was in no way endangered by the state of the appendix.) He was able to leave his bed on the eighteenth day after the operation. The acute persistent character of the appendicular pain disappeared and by attending very carefully to his diet, to hygiene, and by avoiding the least exertion he was able to enjoy quiet short walks and partially to resume his ordinary occupations. His health was thus improved and the spasmodic condition of the bowel, which had been markedly relieved by the removal of the source of reflex irritation, starting from the appendix, had not disappeared entirely but caused very little inconvenience. Constipation had also been greatly ameliorated but the patient still continued to pass as before both mucus and mucous casts. In May, 1906, he had an acute attack of muco-membranous entero-colitis, characterised by constipation, colicky pain more marked in the right iliac fossa than along the transverse colon, and casts. This acute attack was less intense than before the removal of the appendix. In June, 1906, he came again to Chatel-Guyon. On examination I found there was a general spasmodic contraction of the large bowel, but the latter was only slightly tender, even in the right iliac fossa. Constipation was chronic and mucous casts were found in the stools. He could walk standing quite erect instead of nearly bent double as before his operation. After this second visit, and in spite of an acute attack of diarrhœa coming on after severe indigestion, the general health of the patient improved still more. His state of nervous irritability was especially greatly diminished. From September, 1906, to January, 1907, the bowels acted regularly, with quite normal stools and without the slightest trace of casts. In January, 1907, the patient contracted influenza, under the influence of which casts were again passed. He then went through a cure at his home with Chatel-Guyon water and he wrote to me in February saying that although his cure was not complete, yet the bowel had already become normal in its function. Since his last season at Chatel-Guyon he has been feeling quite a new man; he was able to get through a lot of work, do a good deal of driving, and take outdoor exercise in the shape of shooting. He has gained considerably in weight.

I have given the full details of this case, for it constitutes quite a *résumé* of the facts I have described in this article. It shows also that in spite of the modern tendency and belief there are still cases of muco-membranous entero-colitis in which an operation is necessary.

CASE 3. *A case of chronic muco-membranous entero-colitis in the course of which acute appendicular pain, due to a supervening cause—a large appendicular calculus—necessitated operation; recovery.*—The patient, a man, aged 44 years, had lived a long time in Palestine, where he holds a very important and responsible post. In that country 15 years ago he became suddenly very constipated after a violent emotion. Constipation was soon complicated by intestinal pain of medium intensity and the passage of mucus and casts in his stools. In short, the patient began to suffer from muco-membranous entero-colitis, which has lasted ever since. The special feature of this entero-colitis was that in spite of the contracted state of the bowel, the persistent constipation, and the chronic passage of casts, the patient had been remarkably free from very painful paroxysms. Intestinal pain was always bearable. An important fact occurred towards the end of 1905 whilst the patient was still in Palestine. The muco-membranous entero-colitis became suddenly worse and painful paroxysms of the most violent character came on in the right iliac fossa with intense pain. Another attack took place six months later when the patient was in Paris. Both the first and second acute appendicular paroxysms disappeared after medical treatment. However, the pain in the right iliac fossa, which had increased since the first crisis, caused the patient a good deal of anxiety. The idea of returning to Palestine with his appendix in a diseased state and liable to set up complications at any moment was anything but reassuring and his physician suggested the expediency of an operation. It was finally decided, however, that the patient should first try the Chatel-Guyon treatment, where I saw him in 1906, a short time after the second attack. On examination I found all the organs of digestion out of order; the tongue was thickly coated and the stomach was slightly dilated, which in conjunction with the large intestine was the seat of frequent burning sensations. Digestion was slow and difficult. On palpation I noted the cæcum to be very large, in a state of contraction, and very painful on pressure. The sigmoid flexure was also tender and in a state of spasmodic contraction. I was astonished to find that the pain presented its maximum of intensity not at McBurney's point but a little higher up. The patient, however, stated to me very clearly that during the acute paroxysms he suffered terribly in the appendicular and peri-appendicular regions. Besides, the pain which existed in a chronic state was very notably relieved by his wearing a light belt very tightly drawn. Nothing particular happened during his course of treatment at Chatel-Guyon. After leaving Chatel-Guyon he went to Switzerland for a rest and followed there a very strict regimen. He was then feeling much better, but a short time later he was suddenly taken with a third acute attack as intense and as serious as the two former ones. Operation was then decided upon and the appendix was removed "*à froid*." The appendix was found quite behind the cæcum, to which it was firmly adherent. It was imbedded in strong adhesions and removed with the greatest difficulty. When opened it was found to contain an extremely hard stercoral calculus, measuring four centimetres in length and one centimetre in thickness. At the present time the patient is free from pain in his right iliac fossa but still passes a few casts. He has gone back to Palestine.

We have here another example of the condition of an appendix already influenced by the chronic and subdued irritative process of a prolonged muco-membranous entero-colitis which is suddenly complicated by a supervening and unexpected cause, a large stercoral calculus. One can easily understand that in such a case the diagnosis could only be made after operation. The existence of the firm adhesions in this case serves to show how the appendix reacted and protected itself against the irritation due to the calculus.

Chatel-Guyon, France.

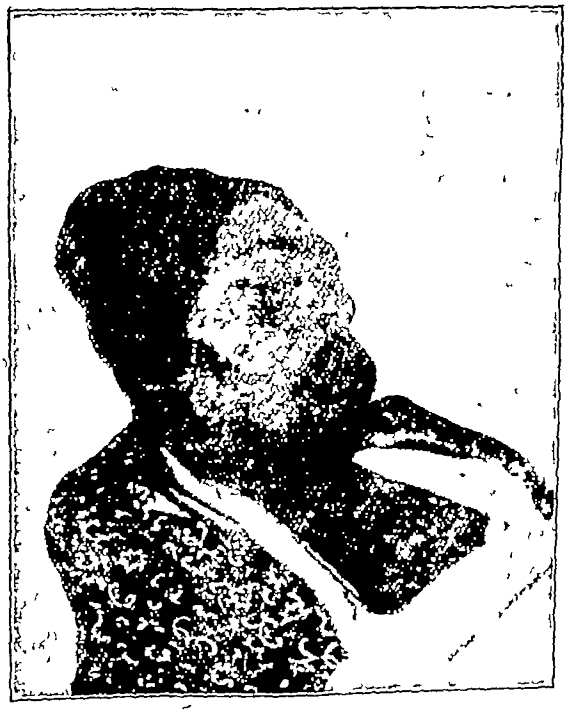
Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

AN ACUTE INFECTIOUS CONDITION (? GLANDERS).

BY HAROLD T. MARRABLÉ, M.B., B.CH. DUB.,
SURGEON TO THE CHURCH MISSIONARY HOSPITAL, ISFAHAN, PERSIA.

THE patient, aged 29 years, a carriage driver between Isfahan and Shiraz, was admitted to hospital on Feb. 16th of this year. He gave the following history. A fortnight previously while on the road he got a severe attack of shivering and fever, which was followed four days later by pain and swelling of both feet. On the 12th, that is, four days before admission to hospital, he became much worse. On admission to hospital the following features presented themselves. The patient, obviously very ill, was unable to walk. Both his feet and ankles were considerably swollen and very painful; his right hand and lower part of forearm were similarly affected. He had a bad cough and some bronchitis; the lungs were clear. He complained of frontal headache and moaned incessantly. The temperature was 102·6° F. and the pulse was 112. Thinking the case was one of acute rheumatic fever I treated him with salicin and ordered the painful joints to be wrapped up with cotton-wool. During the night his temperature came down to 101·2°, his pulse, however, was faster (124) and his respirations, which were 30 per minute on admission, were now 40. During the day (the 17th) numbers of small pustules, of the size of a pin's head, came out over his neck and chest, and his face began to swell towards evening. He was restless and tried to get out of bed during the night and his temperature, 103 6° in the early part of the night, again fell towards morning to 102°. His pulse was now 140 and his breathing was rather more rapid. The first symptom that gave any hint as to the true nature of the malady was an amber-coloured exudate from the nose, at first slight and later copious; this was on the morning of the 18th. Quinine, strychnine, and iron in large doses were administered at frequent intervals during the day and the patient was isolated. On the following morning (the 19th) the patient was much worse. The accompanying reproduction of a photograph taken two hours before death gives but a faint idea of the spectacle which he presented. Large blebs came out during the day on his face and neck and, breaking down, exuded the same amber-coloured fluid that flowed from his nose. His face was extremely œdematous, while the swelling of his feet had somewhat subsided. Several patches of dulness appeared over his lungs and just before death, which occurred at 8 o'clock on the evening of the 19th, his temperature was 104·8°, his pulse was 160, and his respirations were 56.



I could obtain no history of an outbreak of glanders among the post-horses, but the disease does not infrequently occur, and little or no precautions are taken in Persia against its spread.

Isfahan, Persia.

A CASE OF ABERRANT FUNCTIONAL (?) CHRONIC INTESTINAL OBSTRUCTION.

BY G. S. THOMPSON, M.R.C.S. ENG., L.R.C.P. LOND.,
SENIOR RESIDENT MEDICAL OFFICER, ROYAL ALBERT HOSPITAL, DEVONPORT.

THE following is an account of a condition which is so uncommon as to seem worthy of being added to already published cases of the same or an allied nature.

The patient was a child, five years of age, admitted into the Royal Albert Hospital on Oct. 20th, 1906, under the care of Mr. A. G. Rider, for chronic constipation of a most obstinate nature which dated from birth. It was not by any means an unusual event for the patient to go two or three weeks without anything being passed from the bowel; indeed, this was only effected after the constant administration of aperients and enemata. The evacuations were of a hard consistency and made up of small separate masses. Before operation was undertaken nothing had been passed by the rectum for three weeks despite the use of aperients and enemata. On Oct. 29th the abdomen was opened under ether anæsthesia. The sigmoid portion of the colon was then found markedly distended, whilst its wall, besides being unduly red, was relatively much thickened having regard to its distension—showing absence of pressure atrophy. Palpation of this viscus was rendered very difficult owing to the great tension to which all the abdominal contents were subjected. In the pelvis the rectum could be felt as a small hard tube contrasting strikingly with the bowel above the site of the obstruction. The nature of this obstruction, whatever it was, could not be discovered either then or subsequently, and a Paul's tube was therefore inserted into the sigmoid portion of the colon after fixing the bowel to the wound in the usual manner. When the colon was opened considerable quantities of a semi-fluid material were removed which had an exact naked-eye resemblance to quicksand. After this relief the distension became less and less and the abdomen was again quite flaccid in a day or two. On several occasions following the colostomy the fæces became impacted in the bowel above the opening necessitating their removal; this condition produced quite a localised tumour at the part implicated, visible to the naked eye. On Nov. 9th the wound in the bowel was sewn up by Czerny-Lembert suture, this undertaking being rendered somewhat difficult owing to the numerous and soft granulations covering the involved peritoneum; the bowel was replaced in the abdomen and a second search was instituted under more favourable conditions as regards room than on the former occasion, but in vain. Several hard fæcal masses, which were present in the rectum, were now expelled therefrom by pressure. The abdominal wound was then closed, as nothing further seemed possible, leaving a small aperture for drainage below. After the second operation the patient's general condition became bad, distension of the abdomen ensued, nothwithstanding the frequent response of the bowels to evacuants, whilst pressure over the said part produced pain; vomiting followed. There was no dyspnœa, however, at any time. Death occurred on Nov. 14th.

At the necropsy the peritoneum was found to be covered with extravasated intestinal material, for the intestinal sutures had yielded. The bowels were adherent to one another with acute kinks here and there. No obstruction nor any abnormal condition of the rectum or pelvis could be found in spite of careful search.

Previously to the above operative interference the patient had some time before been in hospital but was discharged unrelieved. The medical treatment included the use of thyroid extract, abdominal massage, aloes, and strychnine pills—all, however, to no adequate purpose.

Devonport.

NOTE ON A CASE OF MELÆNA NEONATORUM.

BY J. BASIL PAGE, M.B. LOND.

ON April 30th I was called at 7 A.M. to attend a confinement case. On arrival I found the child and afterbirth were born and the nurse reported that the case had been quite normal and that there had been very little loss before or after the birth. The child was a girl; weight 6 pounds, small, but apparently quite healthy. 36 hours after birth I was hurriedly summoned and found that the child had vomited about a quarter of a pint of blood, rather dark, and with clots. The child was given a few spoonfuls of milk and immediately vomited another quarter of a pint of blood and clots. On the next day, May 2nd, there was blood in the motion, as much as she had vomited, and the motion was very foul. On the fourth day the baby's weight had dropped to 4 pounds; since then she has been progressing well and beyond the facts that she is small and feeble there are no abnormal signs or symptoms. I am sending this description of the case to you, as I have never seen or heard of a similar case. I shall be much obliged if you can find room for this note, as I should like to know if anyone has had a similar case. I may add that the child is now slightly jaundiced.

Bury St. Edmunds.

Medical Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A MEETING of this society was held on May 15th, Dr. W. CRAIG, Vice-President, being in the chair.

Dr. G. H. MELVILLE DUNLOP exhibited: 1. A baby with a Rickety Head, in which craniotabes was unusually well marked. The infant was eight months old and was subject to frequent attacks of diarrhœa and vomiting. There was no syphilitic taint. The fontanelles in the skull were particularly open and the sutures were so wide apart that a finger could be introduced between them. The bones of the skull were particularly deficient, the occipital, temporal, and parietal bones being soft and easily bent. 2. A case of Infantile Paralysis in which the abdominal muscles on one side were affected. This was a very rare condition and it was the first case of this affection which Dr. Dunlop had seen. Dr. Sinclair of Philadelphia had described 370 cases of infantile paralysis but had never met with such a condition. Only one similar case was noted in the Johns Hopkins reports. The child was now two and a half years old and when 18 months old had an attack of infantile paralysis with fever and convulsions. The paralysis was at first widespread, affecting the left and right legs, as well as the abdominal muscles. The paralysis passed off completely from the left leg, but the right leg had always remained weak. The child could walk, but the right leg was dragged and the toes were pointed. The whole of the muscles on the right side of the abdomen were paralysed and when the child cried they were ballooned out. The affected muscles showed a complete loss of reaction to faradic currents. 3. A girl with a Peculiar Scarring of the Skin over the Lower Part of the Back, the result of an attack of herpes zoster. The scars were symmetrical and feathery in appearance. The child, when 18 months old, had had an eruption of vesicles, which became pustular; scabs formed and large ulcers which caused much pain in the lower lumbar and sacral regions. 4. A case of Cretinism after treatment extending over 14 years. Dr. James Carmichael had diagnosed the case when the patient was an infant. When first seen the large tongue was present with the wrinkled condition of the forehead, the broad hands, and other typical signs of cretinism. When the child was two years old thyroid treatment was adopted and growth took place rapidly; the flabby condition disappeared and the intelligence increased during the six months in which he was kept under observation. As the mother neglected him his condition underwent a relapse which improved under renewed treatment. He had had about seven years of continuous treatment and his present condition showed the limits which thyroid treatment might reach. Many of the symptoms of cretinism were present; he was singularly deficient in intelligence and could not be taught the simplest rudiments of education. His determination was great and he was so stubborn that he would not do anything that his mother desired.

Mr. HAROLD J. STILES showed: 1. A baby after operation for the Removal of a Large Hydronephrotic Cyst. The baby was nine months old and was healthy and vigorous, only presenting a very lax condition of the abdominal walls. When three months old the abdomen was enormously distended and this had been present at birth and had caused some difficulty during parturition. On examination a large cystic abdominal tumour was present, extending from below the ribs on the left side to the left iliac fossa and also to the right iliac fossa. The tumour was elastic, smooth, and fluctuating. No urinary symptoms were present. The condition was congenital hydronephrosis. When the child was six months old the tumour was removed through the left loin. The cyst was exposed extraperitoneally, tapped, clamped, and removed. The child made an excellent recovery, and Mr. Stiles was of opinion that such cases should be operated upon during childhood. 2. A boy after Nephrectomy for Advanced Tuberculous Pyonephrosis. The condition was first noticed a year before operation owing to frequent and painful micturition. Hæmaturia had only been observed on one occasion six weeks before his admission. No bladder disease was seen by the cystoscope. A large pyonephrotic kidney was present on the left side and was removed with difficulty because of its adherence. The ureter was ligatured but was not removed. The boy had made an excellent recovery. 3. A girl, aged nine years, after resection of the ileo-cæcal junction and part of the ascending colon for Fæcal Fistula following Suppurative Appendicitis. She had suffered from retro-cæcal appendicular abscess three months ago but at that operation the appendix had not been removed and a week later a fæcal fistula had formed. It was thought that it might have healed spontaneously but 13 months later it was in the same condition; the skin was not excoriated, however. A large mass was present in the right iliac and lumbar regions. This was resected, together with the fistulous opening. There was now no hernia even on coughing. The tumour was so adherent that in removing it an opening was made into the duodenum and a good deal of bile escaped. 4. A girl, aged 11 years, after Partial Resection of the Tibia for Tuberculous Osteomyelitis. For a year previously to operation she had suffered from a painless thickening of the upper two-thirds of the right tibia. It was tender on pressure and caused limping as well as a slight swelling of the knee-joint. The case was one of tuberculous osteomyelitis with secondary deposit of bone beneath the periosteum. Formerly the bone was opened into and was scraped, but very usually the patient returned in a month or two with recurrence of the disease. Now the bone is thoroughly exposed and the periosteum is divided, and by means of a Gigli's saw the bone is cut through in healthy tissue; the diseased bone is then wrenched free from the periosteum and from its epiphysis. The operation in the present case had been performed three years ago and now perfect re-formation of the bone had occurred. On section of the diseased bone a central sequestrum was seen and surrounding it a grey deposit of tuberculous tissue. The ulna had also been resected for a similar affection. Another case of which skiagrams were shown exhibited the disease as affecting the lower two thirds of the tibia. 5. A baby with a Large Encephalocystocele (Partial Exencephalus); the cranial bones had not developed so as to cover in the brain. The tumour overlapped the frontal and parietal bones. The dura mater as well as the bone was absent and Mr. Stiles thought that bone formation took place much more energetically from the dura mater than from the pericranium. Fluctuation from side to side could easily be made out. 6. A specimen of an Enormous Meckel's Diverticulum removed from an Inguinal Hernial Sac in a child.

Dr. J. S. FOWLER showed: 1. A child who developed Fits as a result of Syphilitic Disease of the Cortex. The unilateral fits commenced at the age of ten months and at that time the child exhibited no appearance of congenital syphilis, though this was very noticeable at present. Both parents were syphilitic. The prognosis was not good, as the fits frequently developed into a syphilitic dementia. At first the fits recurred every third or fourth day, but on putting the child on iodide (nine grains per day) the convulsions disappeared. The treatment was continued for some months and when intermitted the child became vacant and dull. The right arm and leg were not moved so freely as were the left. 2. A typical case of Posterior Basal Meningitis. This might be called a sporadic form of cerebro-spinal meningitis. The disease commenced three weeks previously with diarrhœa and vomiting, the child then suddenly became feverish and had lain in the present semiconscious condition for two weeks. There was marked head retraction with bulging of the fontanelles. The child was probably blind and dysphagia was present. Lumbar puncture showed the characteristic diplococcus. The case was identical with cerebro-spinal meningitis and it might be through these cases that the epidemic disease was kept alive.

Dr. J. W. SIMPSON showed for Dr. JOHN THOMSON: 1. A child, aged two and a half years, with Spleno-Medullary Leukæmia. The health had been perfect until six months previously, when fever, vomiting, and weakness of the legs developed. The patient was thought to have had an attack of infantile paralysis, but recovered completely. In January the child was noticed to be very pale and the abdomen to be enlarged greatly. On examination the spleen was found to be enormous, extending down into the true pelvis, and leucocythæmia was very marked. 2. A rickety child showing Large Posterior Beads on the Ribs. The ordinary rosary nodes were seen but on the posterior aspect of the ribs a line of beads were present. These were probably due to the callus thrown out round greenstick fractures caused by lifting up the infant and fracturing the rickety ribs. 3. A boy, aged 11 years, who had been under treatment for four years for Pott's disease. He had been readmitted a week ago suffering from pains in the joints and fingers. Well-marked rheumatic nodules, varying in size from that of a pin's head to that of a pea, were present, chiefly over the elbows and knees. They came out in crops and lasted about three weeks. The nodules were freely moveable and so was the skin over them. They were also found over the ankle, tendons, head, and vertebræ, and might be the only sign of rheumatism present in children. Endocarditis was nearly always present in such cases as it was in the case exhibited.

Dr. W. B. DRUMMOND showed a case of Amaurotic Family Idiocy. The disease was exceedingly rare and all the cases described had occurred in Jewish families. The child was 14 months old and was the tenth child of the family. Until her eighth month she appeared normal but since then there had been no mental development though the physical development was good. The child gradually became more and more apathetic and vision was gradually lost. The ophthalmoscope showed a greyish appearance of the fundus with a bright red spot in the macular region. The usual history was that the weakness and apathy increased and death took place as a rule at the second or third year of life. The eighth and ninth children in this family were twins, and one of them suffered from this disease; the fourth child also died from this disease and very probably the seventh child succumbed to this affection.

Dr. E. W. SCOTT CARMICHAEL showed a boy (a Mongolian idiot) who had been operated on in January for Acute General Peritonitis the result of a streptococcal infection.

Dr. A. DINGWALL FORDYCE exhibited a child with an Uncommon Skin Affection (urticaria pigmentosa) resembling specific eruption. It had been present for 14 months and disappeared when the child was in good health but reappeared during poor health.

EDINBURGH OBSTETRICAL SOCIETY.

Status Epilepticus.—Bilateral Ovarian Dermoid Tumours.

A MEETING of this society was held on May 8th, Dr. J. W. BALLANTYNE, the President, being in the chair.

Professor ROBERT JARDINE (Glasgow) read notes on a case of Status Epilepticus which commenced during labour and ended fatally after 774 fits; the infant also died after many fits. The patient was aged 27 years and in her third labour which had occurred at full time. Her father had suffered from melancholia and a sister, deceased, was afflicted with epilepsy for six years. The patient never had a fit until the onset of labour; there was no evidence of syphilis or any history of injury to the head. The fits were of the ordinary eclamptic type; there was no cry at any time; there were no swelling of the face or the legs and no headache until the evening prior to admission to the maternity. She had 21 fits before being seen. She was then put under chloroform, 16 ounces of blood were drawn from the arm, and three pints of saline solution (one drachm each of sodium chloride and sodium acetate to the pint) were transfused. As the os was half dilated it was dilated completely with the hand and the child was delivered by version. There was considerable bleeding from the lacerated cervix which was afterwards stitched with catgut. For eight hours she was free from fits and could be roused to answer questions. In the following two hours she had 14 fits; a hot pack was given and for five hours there was no recurrence. Two more pints of the saline solution were injected into a vein. She perspired freely. The urine was found to be quite normal without a trace of albumin. On the day after labour the fits returned and were treated with rectal injections of chloral and bromide and more saline injections. Repeated lumbar punctures were then made but no cerebro-spinal fluid could be obtained, but some hours afterwards about an ounce of fluid was withdrawn, which was very slightly opalescent, and the deposit contained polymorphonuclear leucocytes with a large number of small mononuclear leucocytes. The withdrawal did not produce any change in the patient's condition. The fluid escaped from the needle by drops except during the fits when it ran freely. The fits continued very frequently. Stovaine was injected into the spinal canal and in a few minutes the lower limbs were paralysed, followed by diminution of the movements of the arms; the patient became extremely collapsed and the pulse disappeared from the wrist. As she seemed to be dying strychnine was given hypodermically and milk with brandy was injected by a tube into the stomach. The pulse rapidly returned but the collapse continued for a considerable time. On the third day the fits were recurring at the rate of from six to 14 per hour; the kidneys, bowels, and skin were all acting well. Morphine subcutaneously was tried. On the fourth day the fits were almost continuous, up to 32 in one hour. The question of trephining was discussed but it was considered that it would be of no avail. The patient sank that evening. The number of fits recorded was 774. The fits, though so numerous, did not appear to be very exhausting. The infant, who weighed seven and three-quarter pounds, was asphyxiated at birth, but was easily resuscitated. The colour never became quite satisfactory. The child lived for three days and during that time the body was more or less in a state of rigidity, becoming much more marked at intervals. Though there were no convulsions yet many of these fits of rigidity occurred, the body at times assuming a position of opisthotonos, and the fit was accompanied with a peculiar distressful cry and cyanosis. The urine contained a considerable amount of albumin. Chloral hydrate was given to the child in grain doses every hour. On *post-mortem* examination the mother's brain showed marked engorgement of the vessels, much more evident on the left side; the spinal cord seemed normal; the kidneys were fairly normal but there were indications of an old parenchymatous nephritis. The infant's brain showed similar engorgement of the vessels as in the mother's, only both sides were equally affected. Professor Jardine referred to the recent book on Epilepsy by W. A. Turner, where the influence of pregnancy, the puerperium, and lactation is given with the history of 61 pregnancies in 41 epileptic women. Quickening induced a relapse in seven cases. Pregnancy was the original cause in two cases, induced relapse in 14 cases, was temporarily beneficial in six cases, and made no difference in one case. Accouchement was the original cause in five cases and induced a relapse in 17 cases. Lactation was the original cause in three cases and induced a relapse in six cases. With the statement that many cases of puerperal eclampsia are really examples of serial epilepsy or the status epilepticus Professor Jardine disagreed, as he had only seen three patients out of considerably more than 100 cases of puerperal eclampsia who could be considered epileptic. In two there was a history of previous epileptic seizures and in the third there was no albumin in the urine. He had never seen a case of eclampsia in which there was no albumin in the urine. If he had a similar case under his care again he would be inclined to try lumbar puncture and the injection of bromide.

Professor Jardine gave short notes of another case that was quite recently delivered by vaginal Cæsarean section under Dr. J. M. Munro Kerr's care in the Glasgow Maternity. The patient had suffered from fits in her first pregnancy, five years ago, from the third month onwards. In the interval between her first and second pregnancies she had suffered from *petit mal.* She was admitted in her second pregnancy at seven and a half months suffering from fits. There was no œdema. A very faint trace of albumin was present in the urine. She had 49 fits in the four days before and including that on which the operative delivery was carried out, 42 fits on the following day, nine on the next, and two on the next, when they ceased. She was treated with intravenous injection of saline infusion, morphine hypodermically, and chloral and bromide.—Dr. James Ritchie, Dr. F. W. N. Haultain, Dr. J. Haig Ferguson, Dr. W. Fordyce, Dr. F. Porter, and the President made remarks on the paper, and Professor Jardine replied.

Dr. Malcolm Campbell read a paper on Bilateral Ovarian Dermoid Tumours complicating Pregnancy. The rarity of bilateral ovarian dermoids was referred to and the details of a case were given. The patient was 32 years old, had been married for 12 years, and had five children. Prior to admission to hospital she had had amenorrhœa for three months and complained of severe pain in the abdomen. A swelling had been noticed in the right side for six months. On laparotomy being performed an ovarian cyst of about the size of a fœtal head was removed from the right side. The left ovary was also removed, being cystic and of about the size of a hen's egg. Both tumours proved on examination to be dermoid cysts. Six months after the operation she was delivered of a full-time healthy child. The influence of the corpus luteum and its supposed secretion on pregnancy in relation to this case was discussed by Dr. Haultain, Dr. Fordyce, and the President, and Dr. Campbell replied.

Leeds and West Riding Medico-Chirurgical Society.—A meeting of this society was held on May 10th, Dr. A. H. Bampton being in the chair.—Mr. A. E. A. Pearson read a paper entitled "Notes on Cerebro-Spinal Fever."—Mr. Pearson read a paper on Notes on Cerebro-spinal Fever made during a recent visit to the Purdysburn Fever Hospital of the Belfast Corporation. Mr. Pearson gave a brief description of six cases sent to the Leeds Fever Hospital as doubtful cerebro-spinal fever, the greater number of which were cases of tuberculous meningitis, one was a case of typhoid fever, and one was a case of cerebro-spinal meningitis of diplococcic origin but probably not of the specific diplococcus of Weichselbaum. Notes of the latter case were read. In the differentiation of meningitis due to tubercle on the one hand and to diplococci (Weichselbaum's pneumococci or Still's) on the other, stress was laid on the gradually increasing and comparatively early coma usually found in cases of tubercle and to its comparative absence in cerebro-spinal fever, except in the very acute or apoplectic forms. In Mr. Pearson's experience it also seemed that on spinal puncture being made the serum in cerebro-spinal fever was less in quantity and less clear than in tuberculous meningitis. Paralyses and fundus troubles were also less frequent. Mr. Pearson, in referring to the Belfast cases, drew particular attention to early vomiting, headache, delirium of marked character, and loss of consciousness, the last of which, except in the acute fulminant forms, tending to clear soon; also to the early exaggerated retraction of the head, which appeared to be not so marked in adults, to the extreme emaciation, to facial herpes on the third or fourth day of the disease, and to the presence of a petechial eruption on the trunk and limbs in some 30 per cent. of the cases. It was noted that hyperæsthesia was marked in all cases in the acute stages and the presence or absence of Kernig's sign varied, being apparently marked in the early stages and in the later recrudescence of the cerebral symptoms. Small enlargements of the cervical, axillary, and inguinal glands were noted in many of the cases seen. The recorded temperatures of the patients showed extreme irregularity with no defined course and were of a markedly "spiked" kind, some records showing morning elevation and evening depression. The pulse records showed the same wide variety of range. Cardiac murmurs were noted in one or two cases. There seemed to be a tendency to recrudescence or relapse in the third or fourth week, evidenced by return of vomiting, retraction of the head, and intermittency of fever, after the patient had had a period of quietude from symptoms and a feeling of comparative well-being. Convulsions and paralysis did not seem to be of frequent occurrence. Several had paralysis of the external rectus of the eye and nystagmus [illegible] Conjunctivitis and suppurative eye-disturbance were fairly common.—Professor A. S. F. Grünbaum, who also exhibited a specimen showing the diplococcus intracellularis in the cells, Dr. J. E. Eddison, Dr. A. G. Barrs, Dr. T. W. Griffith, Dr. E. F. Trevelyan, and Dr. O. Porter joined in the discussion.—The following specimens were shown:—Mr. C. E. Dawson: A Portable Apparatus for the Administration of Oxygen at the bedside.—Dr. Barrs and Mr. A. Hawkyard: Complete Hydatid Cyst of the Lung, spat up, with skiagram of the chest.—Dr. Trevelyan: A case of Tuberculous Laryngitis one year after laryngotomy was performed for symptoms of obstruction.—Mr. W. Gough: Specimen of Epithelioma following a scar-horn.—Mr. J. J. Anning: Heart with Extreme Stenosis of the Pulmonary Valve from a boy, aged 13 years, dying from pulmonary tuberculosis.—Mr. R. G. Hann: Heart showing Ruptured Aortic Valve.—Dr. W. H. Maxwell Telling: Extremely Cirrhotic Liver from a girl, aged 13 years; (with Dr. O. C. Gruner) Specimen of Acute Infantile Bronchiolectasis.—Specimens and cases were also shown by Mr. Pearson, Mr. L. A. Rowden, Dr. A. L. Whitehead, Dr. J. Allen, Dr. J. Stewart, Dr. T. Churton, Mr. H. Littlewood, Dr. M. B. Ray, Mr. J. F. Dobson, and Mr. B. G. A. Moynihan.

Wigan Medical Society.—A meeting of this society was held on March 21st, Dr. Ferdinand Rees, the President, being in the chair.—A paper on Digitalis, Strophanthus, and Squills in the Treatment of Heart Disease was read by Dr. John Hay.—An interesting discussion ensued and the following members took part: Dr. J. Blair, Dr. A. E. Hodder, Dr. R. Prosser White, Dr. A. Matheson, Dr. K. Fraser, Mr. M. H. Enright, Mr. C. M. Brady, and the President.—A cordial vote of thanks was accorded to Dr. Hay for his paper.——A meeting was held on May 9th, Dr. Rees, the President, being in the chair.—A paper on Ectopic Gestation, which took the form of an address, was given by Professor H. Briggs, numerous specimens and beautiful drawings being exhibited.—A discussion ensued and the following members took part: Dr. Blair, Dr. M. Benson, Mr. W. Latham, Mr. E. H. Monks, Mr. Enright, Mr. C. F. France, Dr. E. Colston Williams, Dr. Matheson, the President, and the honorary secretary.—A cordial vote of thanks was passed to Professor Briggs for his interesting address.

Reviews and Notices of Books.

The Essentials of Chemical Physiology. By W. D. Halliburton, M.D. Lond. Sixth edition. With 82 figures in the text. London: Longmans, Green and Co. 1907. Pp. 258. Price 4*s.* 6*d.* net.

When a work such as the above, written by a teacher of such wide experience as Professor Halliburton, reaches its sixth edition this alone is enough to mark the firm hold which it has on the student of medicine and also seems to show that it has fulfilled its function—namely, that of giving a concise and yet sufficient account of chemical physiology for students of medicine. The present edition shows some changes from previous editions; a few alterations are introduced in the text in small type—that is, the practical exercises which are the outcome of extended experience in the teaching laboratory. The text in large type is descriptive rather than practical and in it we find considerable modifications, more especially in the chapter devoted to proteins (the word "proteid" has been got rid of). The proteins are now classified as follows: Protamines, histones, albumins, globulins, sclero-proteins, phosphoproteins, and conjugated proteins, which last include (*a*) gluco-, (*b*) nucleo-, and (*c*) chromo-proteins. A very full exposition is given of the many new results of investigations on these bodies both in their chemical and in their physiological relations, such as the way in which they are utilised in the body. The other two sections which have been amplified are those on blood coagulation and respiration. Additions have also been made to the advanced part. More especially in this part, in the appendix, will the advanced student find much that is of fundamental importance—indeed, of far more importance than a knowledge of tests and reactions, such as polarimeters, the relation between circular polarisation and chemical constitution, dialysis and osmosis, ions and osmotic pressure, and freezing points in relation to osmotic pressure.

The work meets fully all the wants of the average medical student so far as a knowledge of chemical physiology is concerned.

Traité de Pathologie Interne. (*Treatise on Internal Pathology.*) Par G. LEMOINE, Professeur de Clinique Médicale à la Faculté de Médecine et de Pharmacie de Lille, Médecin de l'Hôpital Saint-Sauveur. In two volumes. Vol. I., pp. 1011; Vol. II., pp. 1015. Paris: Vigot Frères. 1905. Price 16 francs.

THE title of Professor Lemoine's book when translated literally into English is somewhat misleading, since the work is a descriptive text-book of medicine, each disease or morbid condition being described from a clinical standpoint as well as from the pathological point of view. Its special feature is the application of pathology to the elucidation of the phenomena of disease and in general arrangement it conforms closely to some of the English text-books of medicine, notably the well-known one of Professor Osler. Each disease is briefly defined, a paragraph is devoted to its history, then its etiology, pathology, symptomatology, diagnosis, and prognosis are considered, while a brief paragraph on treatment, or rather the main principles which determine treatment, is appended. The sections on the history of the various maladies are good and in many of them justice seems to have been done to the work of English investigators, which makes it all the more surprising that in the consideration of malaria although the main outlines of the work of Ross and Manson are given their names are not mentioned in connexion with the disease.

The first volume deals with the infectious diseases, disorders of nutrition, and diseases of the blood and of the respiratory and circulatory systems. In all cases the descriptions are clear, and the problems which are involved in the pathology and etiology of each disease are discussed in an interesting and critical manner. The symptomatology is in every case detailed and arranged conveniently. In some of the less common diseases the descriptions are unusually exact and should be useful for purposes of reference. It is interesting to note in several instances the different grouping adopted from that usual in this country; for instance, one section entitled "Infectious Pseudo-rheumatism" deals with the various affections of the joint which are sometimes observed in association with the following conditions: gonorrhœa, septicæmia, scarlet fever, erysipelas, syphilis, typhoid fever, variola, mumps, influenza, measles, and diphtheria, each of which is separately considered. This arrangement is a convenient one and illustrates the similarity in origin of these various conditions. In considering diseases of the lungs primary active congestion is regarded as a disease distinct from pneumonia, and three forms are described—the pneumonic type or Woillez's disease, the pleuro-pulmonary type, and the spleno-pulmonary, each of which is dealt with separately. The diseases of the pleura are most carefully discussed and the account of inter-lobar empyema is the best with which we are acquainted. The frequency with which this condition results in the expectoration of pus is indicated and attention is drawn to the fact, first pointed out by Dieulafoy, that in some cases a fœtid odour of breath, probably due to commencing leakage, occurs as much as from 24 to 36 hours before the actual rupture of the abscess. The section devoted to diseases of the heart and blood-vessels is prefaced by a chapter on Cardiac Semeiology which forms an interesting introduction to their study. The general descriptions of the individual lesions conform closely to those in English text-books and there is little noteworthy about them. Here, again, although Professor Lemoine frequently quotes English authorities in his historical accounts he refers but little to contemporary English writers.

The second volume deals with the diseases of the digestive tract, the liver, the peritoneum, the pancreas, the kidney, and the nervous system, and with certain intoxications. Diseases of the digestive organs are described in considerable detail and the different morbid conditions are clearly distinguished. Among the sections of special interest may be mentioned those dealing with hyperchlorhydria, of which three forms are differentiated—that with paroxysms at intervals, that with daily attacks, and the continuous form or Reichmann's disease. Cirrhosis of the liver is also very well described and the main classification is very closely similar to that usually adopted in this country, although many extra varieties are separated. The morbid conditions referred to the liver in association with tuberculous disease are also more numerous than those usually recognised by English writers. Diseases of the pancreas, on the other hand, receive but little consideration, acute and chronic pancreatitis and cancer of the pancreas being the only conditions of which an account is given. More than half of the second volume is devoted to diseases of the nervous system, which are very thoroughly considered. This section is illustrated by numerous anatomical drawings, diagrammatic figures, and reproductions from photographs which serve to enhance the descriptive value of the text.

The treatise, as a whole, forms a useful text-book and one which we can strongly recommend. It is, moreover, written in the pleasing literary style which we are accustomed to expect from French physicians.

Essays in Pastoral Medicine. By AUSTIN O'MALLEY, M.D., Ph.D., LL.D., and JAMES J. WALSH, M.D., Ph.D., LL.D., &c. London, New York, and Bombay: Longmans, Green, and Co. 1906. Pp. 363. Price 10*s.* 6*d.*

THE intention of the authors of this book is to discuss questions which lie upon the borderland of medicine and theology, for the benefit and information of the physician and the clergyman. The volume will, we think, be found equally helpful to both and is up to date. The avowed object of the authors in publishing these essays is "to offer the medical doctrine of the present day on the questions considered, and that as completely as is necessary to draw the moral inferences." Dr. O'Malley is pathologist and ophthalmologist to St. Agnes Hospital, Philadelphia, and Dr. Walsh is adjunct professor of medicine at the New York Polyclinic School for Graduates in Medicine and professor of nervous diseases and the history of medicine, Fordham University, New York. The book shows ample evidence of the capacity of the writers and of their careful and conscientious study of all points discussed.

The range of subjects covered is vast, including Ectopic Gestation; Abortion; Miscarriage and Premature Labour; the Cæsarean Section and Craniotomy; Human Terata in reference to Baptism; Heredity, Physical Disease and Moral Weakness; Certain Aspects of Intoxication; Social Medicine; Hypnotism; Suggestion and Crime; the Exact Moment of Death; School Hygiene; Criminology and the Habitual Criminal; Paranoia, a Study in "Cranks"; Suicides; Syphilis and Marriage; Social Diseases; Impotency in the Male and Female; Neurasthenia; Hysteria; Menstrual Diseases; Disease and Responsibility; Epilepsy and Responsibilities; Impulse and Responsibility; besides many other topics of great interest, such as Bloody Sweat. Needless to say, such a variety of subjects opens a boundless field for discussion, which the authors have not failed to avail themselves. The dissertations upon Ectopic Gestation, Abortion, Miscarriage and Premature Labour, as well as those on Cæsarean Section and Craniotomy are specially interesting. They may not satisfy all readers, but that would be impossible. It is certain that able theologians differ upon some important points concerning these subjects and it should not be forgotten that it is one thing to sit down in the study and to put forward views upon different problems and quite another matter to stand by a bedside as a physician, and as such to decide, while one or more lives are at stake what is the right course before God to pursue.

We think that many physicians and clergymen who of necessity are deeply interested in the topics at issue will be glad to find a place for this volume in their libraries. We know only one other treatise on the same lines and that is Medicina Pastoralis by Dr. C. Capellmann, Aquisgrani, Sumptibus Rudolphi Barth, 1890. This work, however, has, we regret to say, a limited value, for it is written not only in Latin but in scholastic Latin, a language with which many busy practitioners have but little acquaintance. The publishers of these "Essays in Pastoral Medicine" have done their part admirably.

LIBRARY TABLE.

Dental Materia Medica, Therapeutics, and Prescription Writing. By ELI H. LONG, M.D. Illustrated with seven engravings and 18 coloured diagrams. Second edition, thoroughly revised and enlarged. London: Hodder and Stoughton. 1906. Pp. 298. Price 15s. net.—This book embraces all that the dental surgeon requires in the conduct of his practice. The contents are divided into four parts. In the first general matter connected with drugs and medicines is considered—namely, their constituents, classification, methods of administration, action, and so on. Parts II. and III. deal with local and general remedies. The drugs are not dealt with alphabetically but are classified under definite headings, such as depletives, escharotics, bleaching agents, alteratives, and sedatives. This plan certainly has advantages but it also has disadvantages, as it does not clearly bring out the general properties of individual drugs. The question of prescription writing, together with a table of poisons and antidotes and an index of drugs form Part IV. From many points of view the book is excellent, one feature being the capital diagrams illustrating the action of important drugs, such as cocaine, belladonna, and ether. Into the subject of anæsthesia the author enters fully and he has some very sensible remarks on the use of patent preparations.

The Care and Nursing of the Insane. By P. J. BAILY, M.B., C.M. Edin. London: The Scientific Press, Limited. 1907. Pp. 97. Price 1s. net.—The first part of this book consists of a short *résumé* of the anatomy and physiology of the human body. The author endeavours to make his descriptions of these subjects as simple as possible but in so doing he is sometimes misleading and is liable to leave a wrong impression upon the mind of the reader. The account of the circulation of the blood is good and the physiology of the digestion is also lucidly given. Taken as a whole this will be found a useful little volume for teaching purposes and it also has the advantage of being cheap and well illustrated.

Case Teaching in Medicine. By RICHARD C. CABOT, B.A., M.D. Harvard, Instructor in Medicine in the Harvard Medical School. Boston, U.S.A.: D. C. Heath and Co. 1906. Pp. 214.—In this book the author supplies a series of graduated exercises in the differential diagnosis, prognosis, and treatment of actual cases of disease. As Dr. Cabot says in his introduction, the most important lesson to be learned by every student of medicine is the art of recognising the *physical signs of disease.* With the basic facts we can become familiar only by direct contact with patients and by long practice. But these data of physical diagnosis have to be interpreted. They do not crystallise spontaneously into conclusions. They do not arrange themselves in those groups which we call diseases. They have to be worked up into diagnoses by a reasoning process and this process needs practice. To aid the teacher in training his pupils to think clearly, cogently, and sensibly about the results of physical examination is the object of this book and to this end Dr. Cabot narrates and considers a series of well arranged and instructive cases. The book should be useful to advanced students as well as to practitioners.

Norway as a Winter and Summer Health Resort. By A. MAGELSSEN. Kristiania: Printed by Nikolai Olsen. 1906. Pp. 48.—Many of our readers will remember the description of the inhospitable Scandinavian climate given in the opening chapters of Voltaire's "History of Charles XII. of Sweden." In the present work Mr. Magelssen gives a different view of the same phenomena, showing that Norway, although agriculturally unimportant, nevertheless offers remarkable climatic advantages to seekers after health. In spite of its northerly position mild south-westerly winds prevail and the ocean currents which flow to the coasts help to raise the temperature. One effect of this is that the Norwegian coast temperature is much higher than might have been expected, for the January isothermal of – 5° C. coincides with the whole Norwegian coast. For the purpose of comparison it may be mentioned that the January isothermal of + 5° C. (i.e., 10° C. higher) passes almost in a straight line from Liverpool to near Bordeaux. Norway has, of course, for many years been a favourite summer resort of tourists from Great Britain and certain parts of continental Europe but the work before us is principally devoted to the therapeutic possibilities of the country. It is therefore pointed out that the greatest part of the west coast does not, in spite of the exceptional winter temperature, present a convenient climate for sick persons. The winter is comparatively mild but also damp and windy, whilst the summer is neither dry nor warm. Districts more inland, and especially the alpine and subalpine ones, are therefore recommended for patients. The alpine climate in Norway is reckoned as being between 2500 and 3000 feet above sea level and the subalpine climate as being from 1500 to 2500 feet above sea level. The author states that in winter, spring, and autumn, when residence at the higher levels is impracticable, invalids will find the climate of the subalpine or lower mountain belt much better than that of the lowlands. Various parts of the Gudbrandsdalen area supply examples of both alpine and subalpine regions.

The Special Temptation of Early and School Life. By C. G. WHEELHOUSE, F.R.C.S. Eng., D.Sc. Fourth edition. Leeds: H. Walker. Price 3d.—This pamphlet was first published in 1885 at the request of the Ripon Diocesan Conference; it is an attempt to solve the difficulty of approaching a pure and healthy-minded child on the subject of sex and the mischief of onanism. There is probably now a consensus of opinion that boys on nearing the age of puberty should not be kept in ignorance of the nature of the generative mechanism and the evils consequent on its abuse, knowledge being preventive of prurient curiosity and its attendant evils. Mr. Wheelhouse has undertaken the difficult task of presenting the necessary knowledge to an innocent-minded child who is about to enter a large school; the pamphlet is to be put in the latter's hands for a time sufficient for him to master its contents and then to be returned to his father or master. If the boy does not fully understand it the ice is broken for further explanation. The author has well discharged his task and the book in the hands of a young child should be productive only of good; the subject is approached with tact and explained on lines of natural law. The utility of the pamphlet has, no doubt, been already great and we believe that many of our readers may like to know that a fourth edition has appeared.

The Infant, the Parent, and the State. By H. LLEWELLYN HEATH, L.S.A., D.P.H. Cantab. London: King and Son. Pp. xv.–191. Price 3*s.* 6*d.*—We trust that the increased production of books intended for public distribution on the problems of infant life and death is the consequence of a real demand for them; provided they are written by a competent authority who can command even a limited audience amongst intelligent persons, we are in complete sympathy with them. The work before us is not only written with a full knowledge of the statistics and results of other authorities but is enriched with some interesting information gathered by the author himself. An analysis in a large town, for instance, of an infant mortality-rate of 151 per 1000 below the age of 12 months revealed the fact that during the first week of life the rate was so high "that were it to continue at the same figure for 42 weeks every infant born alive would have succumbed within such period." The author's observations support Dr. Vilderman's experience in Paris that the death-rate is four times as great amongst bottle-fed babies as amongst those nourished at the breast; in fact, breast-feeding may be said to be the predominant note in this book. So strongly does the author feel on this point that he condemns the distribution by local authorities of pamphlets of instruction in proper methods of hand-feeding, as he considers that they may unduly exalt the latter method. But there are two sides to this question: it is extremely doubtful whether any mother who intended to suckle her child would be deterred by such a pamphlet, and many ignorant mothers who would in any case bring up the child by hand may by this means be led into correct ways of doing so. Mr. Heath reviews the methods of milk distribution for hand-fed babies adopted in London and gives an appreciative account of the late Professor Budin's admirable work in the establishment of the French "Consultations de Nourrissons"; he shows, moreover, that this system may be extended at little expense. The extreme importance of the proper feeding of the pregnant and lactating mother is insisted upon as is also the responsibility of the State in its illegitimate children. The book is certainly a useful contribution to the subject with which it deals and in the hands of people with leisure and inclination to devote themselves to social work may well be productive of practical good.

JOURNALS AND MAGAZINES.

The Journal of Anatomy and Physiology. April, 1907. London: Charles Griffin and Company. Price 6*s.* net.—This number contains the following articles: 1. Description of a Human Embryo of 23 Paired Somites, by Peter Thompson, M.D. Vict., Professor of Anatomy, King's College, London. With three plates and five illustrations. Professor Thompson gives a very interesting description of a wax-plate model of an embryo which he constructed from one measuring 2·5 millimetres obtained at an operation. The total length of the model when completed was 244 millimetres. In addition, other models of special organs—viz., the heart, the brain, a part of the alimentary canal, and the septum transversum—were constructed. The nervous system was closed except in the region of the tail where there was a posterior neuropore. The author points out that late closure of the caudal portion of the neural tube is not the invariable rule and enumerates five cases from the literature in which variations have occurred. "With differences such as these it seems impossible to state any definite time, length of embryo, or number of somites with which complete closure might be associated." The flexures of the brain in this specimen differed so much from those which are generally regarded as primary cerebral flexures that Professor Thompson suggests the possibility of the formation of temporary bends which precede the primary flexures usually described. Two lung buds are visible as outgrowths behind the fourth pair of pharyngeal pouches. This lends support to the view of "a few who believe in a paired anlage and regard the mammalian respiratory apparatus as arising from primitively paired structures." The model of the heart is of special interest in that it contains a clear indication of a fourth chamber, the bulbus cordis. A description of the septum transversum and the liver is to be published at a later date. 2. The Form and Nature of the Muscular Connexions between the Primary Divisions of the Vertebrate Heart, with eight illustrations, by Arthur Keith, M.D. Aberd., and Martin Flack, B.A. Oxon. In a paper contributed to THE LANCET of August 11th, 1906, p. 359, the writers confirmed and extended the discovery of Tawara relating to the system of peculiar musculature (the auriculo-ventricular system) within the mammalian heart. The present paper sets forth the results of an extended inquiry made with three objects in view: (1) to ascertain the extent, nature, and position of the muscular connexion or connexions between the primary divisions of the heart in all classes of the vertebrate kingdom; (2) to seek in the sinus, auricle, and bulbus cordis for a differentiation in form and structure of a system of muscle fibres corresponding to that now known to exist in the ventricle; and (3) to trace the evolution of the auriculo-ventricular muscular system as found in the human heart from the simpler and more definite form seen in the hearts of fishes. The hearts examined were obtained from fishes, amphibia, reptilia, birds, and human and other mammals; the method of preparation, a modification of Kaiserling's, is fully described. The results of the investigation are tabulated in a concise summary. 3. A Three-chambered Heart in an Adult, aged 35 years, by Professor A. H. Young, F.R.C.S. Eng., LL.D., University of Manchester. Illustrated. The patient to whom this heart belonged presented the usual signs of one suffering from chronic heart disease. The area of cardiac dulness was increased; the apex beat was in the fifth interspace slightly to the left of the nipple line; there was no thrill. A systolic murmur was audible on auscultation. At the necropsy the external appearances of the organ suggested no abnormality. Further examination revealed only a single functional ventricle containing practically no trace of a division. The inter-ventricular septum was represented by a small ridge situated about the middle of the posterior wall of the common ventricle, while a larger ridge on the right of the posterior wall represented the right infundibular band. The remains of the bulbus cordis, in the shape of a small triangular fossa, were situated immediately to the right of the latter ridge. The aorta and pulmonary arteries were transposed. The paper concludes with some observations on the Causation of Cyanosis by Professor J. Lorrain Smith. 4. New Studies on the Folding of the Visual Cortex and the Significance of the Occipital Sulci in the Human Brain, by Professor G. Elliot Smith, M.D., F.R.S. Illustrated. This is an abstract of one section of a paper read before the Anatomical Society of Great Britain and Ireland in Belfast in 1906 and is also a sequel to an article published in the Records of the Egyptian Government School of Medicine, Vol. II., 1904. 5. Report on a Cranium with greatly Reduced and Irregular Dentition, by W. L. H. Duckworth, M.D. Cantab., Sc.D. The cranium described is a recent addition to the Anatomical Museum. 6. Description of a Human Cranium from Walfisch Bay, South-west Africa, by W. L. H. Duckworth. The writer points out that "apart from the anomalous condition of the malar bones (os malare bipartitum), the small size of the skull suggests a comparison with the female Bush cranium, but, on the other hand, the conformation of the face is entirely unlike that of the ordinary Bush skull." He also refers to the resemblances between the Walfisch Bay skull and one labelled "Bushwoman" in the Cambridge collection and suggests that both are representatives of races inhabiting South-west Africa and only remotely allied to the true Bush race. 7. Some Rare Abnormalities in Teeth, by W. Ramsay Smith, D.Sc. Adelaide, M.B., C.M. Edin., Adelaide, South Australia. Illustrated. 8. Notes on a Prehistoric Skeleton found in a Cave in Littondale, Yorkshire, by C. A. Hill, B.A., M.B., B.C. Cantab. *Illustrated.* Dr. Hill considers the skeleton to be that of a woman who lived towards the termination of the Bronze age and from the fact that there is a jagged hole above the right mastoid process, which might have been caused by a weapon, thinks that she must have hidden in the cave and there succumbed to her injuries. The configuration of the femur is highly suggestive of the antiquity of the skeleton. 9. (*a*) Abnormalities of the Pyramidal Tracts; (*b*) The Causation of the Symmetrical Thinning of the Parietal Bones in Ancient Egyptians; (*c*) on Certain Peculiarities of Brains Lacking a Corpus Callosum; and (*d*) Asymmetry of the Brain and Skull, by Professor G. Elliot Smith.

The Scottish Medical and Surgical Journal.—The May number of this journal deals, so far as the original articles are concerned, entirely with therapeutics. Dr. E. F. Macleod Neave discusses the action of digalen, a new preparation of digitalis introduced by Professor Cloetta, and decides that it is less powerful and more expensive than the official tincture or digitoxin; it possesses the advantage of being less irritant. Dr. Angus McGillivray speaks highly of argyrol in ophthalmic practice in spite of its failure *in vitro* as a germicide, and Dr. J. S. Purdy records some satisfactory results in the treatment of gonorrhœa by irrigation, which were dealt with in THE LANCET of May 18th, p. 1377. For the treatment of acute otitis media Dr. Henry Peterkin recommends free and early incision of the membrane and the use of peroxide of hydrogen; he deprecates allowing the patient to insufflate boric acid or other powder. Dr. J. McIntosh summarises the results which he has obtained in the Royal Aberdeen Hospital for Sick Children from the use of tuberculin (T.R.). The opsonic index was raised by the treatment ($\frac{1}{500}$th of a milligramme every ten days) but the general results were not encouraging.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

DESICCATED SOUPS.

(Henderson and Co., Star Chambers, 30, Moorgate-street, London, E.C.)

We have received a number of desiccated soups which we understand are prepared from formulæ designed by Captain Cookesley. We have made practical experiments with these soups with the most satisfactory results; they are one and all palatable and appetising. It speaks well both for the choice of ingredients and their preparation in a more or less dry state that a pint of good soup can be quickly prepared from a small tin full of a powder which does not look particularly interesting. We are inclined to give the palm to the mulligatawny soup which is really excellent, and to the soup described as special antarctic. Besides these, however, there were green-pea soup (which is quite good), pea soup, and Scotch broth.

(1) SOLOID NIZIN; (2) ELIXOID PINE TAR COMPOUND; AND (3) ELIXOID FORMATES COMPOUND.

(Burroughs, Wellcome, and Co., Snow Hill Buildings, London, E.C.)

1. Nizin is described as a zinc salt of sulphanilic acid and while being a powerful antiseptic is said to be without local irritation on application; it is also claimed that its absorption does not lead to toxic symptoms. A strong solution of the salt does not coagulate albumin. Nizin is suggested for use in urethral and vaginal injections and in eye affections. The soloid contains two grains of the zinc salt. 2. The elixoid pine tar compound is an elegant fluid preparation with agreeable flavour containing pinol, tar, terpin hydrate, Virginian prune, tolu balsam, and ipecacuanha. The formula suggests the probable value of this compound in the treatment of respiratory affections. 3. We have already referred to the tonic and stimulating effect on nerve and muscle following the internal administration of the formates. The elixoid formates compound contains the formates of calcium, sodium, and magnesium. There is nothing objectionable in regard to the flavour of the compound; on the contrary, it is pleasant.

SAUTERNE.

(Hatch, Mansfield, and Co., 47, Pall Mall, London, S.W.)

It is correct to describe this wine, though it may be in colloquial terms, as being clean on the palate, light, and delicate. We have not examined a Sauterne of a lower alcoholic strength than this wine. There can be little doubt that the colouring matters, and with these the tannin of red wines, disagree with some people and in such cases a light Sauterne such as this is dietetically suitable. Analysis showed the following results: alcohol by weight, 10·08 per cent.; by volume, 12·49 per cent.; extractives, 2·95 per cent.; mineral matter, 0·25 per cent.; sugar, 1·00 per cent.; fixed acidity reckoned as tartaric acid, 0·50 per cent.; and volatile acidity reckoned as acetic acid, 0·17 per cent. The wine contains a small quantity of sulphurous acid derived, doubtless, from the "sulphuring" of the cask. There is no objection to sulphurous acid, so long as the amount is kept within limit. We have examined no sample of Sauterne free from it, its presence being necessary to provide against undesirable secondary fermentation.

"SANCOL" GRAPE JUICE.

(Compagnie Française des Vins Fins Sans Alcool, 4, Lime-street, London, E.C.)

The samples sent to us are stated to be grape juice from the Touraine, Bordeaux, and Bourgogne districts. We examined them carefully and found that they are substantially as described—i.e., unfermented, free from alcohol, and free from preservatives. They represent in fact fresh grape juice which has been pasteurised. We give the analysis of the grape juice from the Touraine district: extractives, 17·30 per cent.; sugar, 16·65 per cent.; mineral matter, 0·15 per cent.; and tartaric acid, 1·00 per cent. The samples possessed a pleasant acidulous flavour.

GOATS MILK.

(J. Verity, Hope Villa, Birkbeck-road, Beckenham.)

There are points about goat's milk in connexion with infant feeding which deserve more attention than they have hitherto received. It is well known, for example, that the goat is remarkably resistant to tuberculosis; moreover, the milk appears to be more digestible than cow's milk because its casein forms a flocculent rather than a hard, cheesy curd. It has been stated, however, that the unpleasant odour of goat's milk is an unfavourable feature. As a matter of fact, goat's milk can be as sweet in this regard as cow's milk so long as the animals are kept under clean and proper conditions. A sample of goat's milk submitted to us by the above firm was perfectly sweet to the taste and smell, and there was no suggestion at all of the so-called goat flavour. The milk represents the drawing from a mixed herd which is entirely stall fed, the dry foods given in the winter being replaced by a liberal allowance of grass and green-stuff in the summer. The animals are carefully groomed and their udders are washed daily. On analysis the milk gave the following results: total solid matter, 14·57 per cent.; milk sugar, 5·05 per cent.; fat, 5·27 per cent.; protein 3·43 per cent.; and mineral matter, 0·82 per cent. It will be seen that the milk is of excellent quality, containing a maximum proportion of fat. The sample was contained in a glass bottle fitted with a patent disc cover.

COLD CREAM.

(BARNETT AND CO., 126, BRISTOL-STREET, BIRMINGHAM.)

"Cold cream" is a useful application and it is important that it should be made with good and pure materials. We believe this to be the case with this sample. It is beautifully white and is satisfactorily compounded with water. The oily basis is permanent and proof against becoming rancid. The evaporation of the water in cold cream accounts probably for its cooling quality.

PLASMON BREAD.

(LOWE AND SONS, 72, PRINCES-SQUARE, LONDON, W.)

Plasmon bread represents bread in which the proteins have been augmented by the addition of plasmon or milk protein. Our analysis confirms the statement in regard to this addition, for the total protein in the bread was 7·81 per cent. which represents a considerable advance on the protein contents of ordinary bread. The average amount of protein in ordinary white bread is 6·0 per cent. It is, however, frequently much lower in bread made from indifferent flours. The moisture amounted to 44·12 per cent. and the mineral matter to 0·52 per cent. The texture of the bread is excellent and its flavour is satisfactory. In practice it requires some skill to incorporate adjuvants with the dough and at the same time to produce a satisfactory loaf.

TYPHOO TEA.

(SUMNERS, LIMITED, 8, CASTLE-STREET, BIRMINGHAM.)

We are glad to find that this tea is not "chemicalised," for in our view tea that has been chemically treated is objectionable. Typhoo tea, it is stated, consists entirely of the fringe of the leaf, the inner parts, stalks, and stems being rejected. According to this leaf tips are obtained which, if not free from tannin, do not contain tannin of that rough description present in the centre and stem of the leaf. Our analysis, at any rate, shows that the tannin in typhoo tips is less than half of the amount contained in ordinary tea. More than this, the tannin present does not appear to be so astringent as does that extracted from the ordinary tea leaf. The result is that the infusion of tea made with typhoo tips is peculiarly soft to the palate and entirely free from roughness, yet the flavour is that of excellent tea and the stimulating alkaloid theine occurs in maximum amount Typhoo tips present the appearance of chopped-up leaves. It is not unlikely that this tea may be found suitable by persons with whom ordinary tea disagrees in some way or other.

GRAPHIC CLUB CIGARETTES.

(KAPLANS, LIMITED, 69, BUCKINGHAM-GATE, LONDON, S.W.)

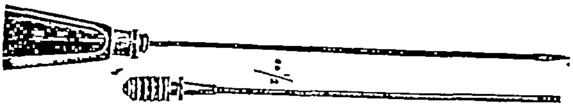
These cigarettes evidently consist of choice selected Dubec leaf. The smoke from them is somewhat full flavoured but free from acrid properties. The cigarette is well packed and free from dust.

WATER-SUPPLY OF BASINGSTOKE.—The new waterworks for the borough of Basingstoke have just been completed at a cost of nearly £20,000.

New Inventions.

A NEW TROCAR AND CANNULA FOR LUMBAR PUNCTURE.

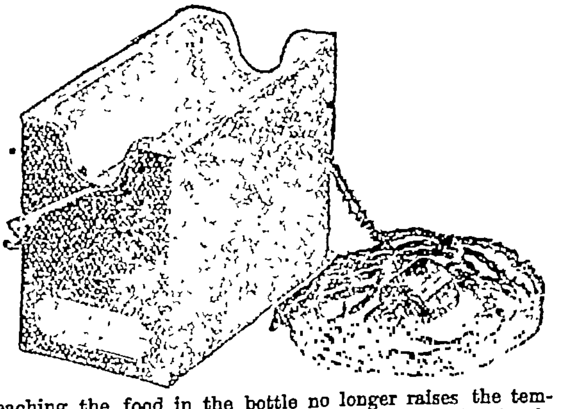
THIS instrument, which is represented in the accompanying illustration, is designed to simplify lumbar puncture and consists of a long trocar and cannula. The latter is made long so that the fluid may be easily led into a sterile vessel or culture tubes and is flexible so that no damage may be done if the patient moves. The use of the extension piece is to lengthen the cannula so that the point of the trocar is protected when being boiled or carried in a case. The instrument is made for me by Messrs. Maw, Son, and Sons, Aldersgate-street, London, E.C.



A. CARNARVON BROWN,
Great Northern Central Hospital, Holloway-road, N.

THE ELECTRIC HYGIENIC FOOD WARMER.

NOT a few will readily admit the troubles and inconvenience attendant upon keeping at hand a supply of suitably warmed food for infants' or invalids' use at all times through the day or through the night. The simple adaptation of the electric current for heating effects in the "hygienic food warmer" promises to reduce this trouble and inconvenience to a minimum. In this apparatus an electric incandescent lamp is employed, the resistance of which may be so adapted to any given main supply that the heat of the lamp will slowly bring milk or other liquid food to a definite temperature, say, between 100° and 110° F., and will maintain it there. The lamp is situated at the base of an open box. Immediately over the lamp is a perforated metal shelf on which the bottle, preferably of the hygienic type or boat-shaped, rests. With the right lamp, adapted that is for the voltage of the particular circuit, it is impossible to cook the food or to raise it above the temperature suitable for administration, and thus the warmed food is available at any hour. A point, of course, is attained when the heat reaching the food in the bottle no longer raises the temperature, the excess disappearing by radiation. The bottle may be protected by placing a cloth covering over it. The heat evolved should be sufficient to bring the temperature of the food to about 100° in three hours without a cover. With a cover or with a small quantity of liquid in the bottle the time will be shorter, but the use of a cover can readily be decided upon according as to whether the temperature at starting is high or low as in summer or winter. Practically the apparatus is automatic and does its work with little or no attention. A hook is attached at one end of the warmer on which a watch may be hung, a slit below allowing light to strike the face of the watch so that the time can easily be read. The adaptation of the electric current for this purpose is an excellent idea which should be very generally appreciated. It is stated that the cost of the electricity for the purpose of working the warmer is less than 1*d.* per day for continuous service. The model which we examined was submitted to us by Messrs. Reavell Bros. and Co., of Bondgate, Alnwick.



THE LANCET.

LONDON: SATURDAY, MAY 25, 1907.

The Plague in India.

TWO years ago when the Plague Commission was appointed to study some of the problems connected with plague we ventured to state that, though it was a step in the right direction and one of which we approved, the gravity of the situation demanded very much more. We held that administrative measures based on existing knowledge which the researches of the Plague Commission have since borne out and emphasised should at the same time have been organised and put into force. These views were later fully supported by a deputation of the Royal College of Physicians of London, headed by its President, Sir RICHARD DOUGLAS POWELL, which waited on the then Secretary of State for India in July, 1905. It was pointed out by this deputation that the calamity in India, in the proportions which it had already attained in 1905, was comparable to the most terrible pestilences recorded in history, not excepting the plague of 1348, often called the Black Death, which completely altered the social conditions of England and of other parts of Europe; and that the continuance of plague constituted a danger not only to the affected provinces in India but also to the rest of India and to the Empire. It was further pointed out that as the epidemic continued the social and economical disorganisation which followed former great epidemics of plague was likely to recur. The deputation left with the Secretary of State for India a memorandum on plague, setting forth these views and recommending the organisation of a specially trained sanitary service for India. It was recognised that some time must elapse before such a service could be fully at work, but Mr. MORLEY'S recent answer to Dr. V. H. RUTHERFORD'S question in the House of Commons must have come as a painful surprise to all those interested in the welfare of India and of the Empire. Mr. MORLEY announced that no scheme had yet been formulated. It is doubtful whether the Government of India has ever realised its grave responsibility in this matter of plague and it cannot be congratulated upon having awakened to it even now. It does not seem to have occurred to the Government of India or to the India Office that the ordinary routine in which it takes years for a proposal to be considered and to be adopted cannot apply to schemes against plague. During the time in which the Government of India is supposed to have been preparing an organised campaign against plague over a million people have died, many of whom, we believe, could well have been saved. It is not oriental procrastination or slow formulation of schemes but action that is required; not resolutions, of which there have been many, but money and machinery.

Perhaps, now, when there is so much unrest in India, which is doubtless due to several causes, political and otherwise, but not least among which are the pathological, social, and economical conditions arising from the annual devastations of plague, action will be taken and taken quickly. When people are dying in such immense numbers their relatives, friends, and compatriots are prone to think that any order of things other than that existing will be better for them, as it may give them relief from their sufferings and distress; they are not at such times in the mood or condition of mind to be very particular as to the manner in which they may exhibit their dissatisfaction and longing for change. The appalling state of things in India and the sufferings of our Indian fellow subjects are only faintly represented by the figures which Mr. MORLEY has given to the House of Commons. In January of this year there were 58,000 deaths from plague, in February there were 98,000, in March 171,000, and in April 314,000, making a total of 641,000 deaths for the first four months and a grand total of 5,326,000 deaths approximately since the plague began in 1896. The shudder that must have gone through the House on the announcement of these figures may be imagined, for not one of its Members, not even the most prosaic or unimaginative among them, could shut his mind's eye when the veil was lifted for a moment; all must have pictured the scenes in that distant country the inhabitants of which are dying in their thousands in the agonies of plague. And yet it is safe to say that few of the Members knew that plague existed in India in epidemic form in any unusual proportions. For ten years they have been hearing references to plague in India, and they have become like the public ready to regard the condition as normal and irremediable. The suggestion made two years ago that the India Office should publish regularly in the English public press the plague returns for India seems for some unexplained reason not to have been carried out for more than a few weeks in 1905. What motive has lain behind this alteration of policy?

We trust that now that the magnitude of the devastation is known no time will be lost in organising the special service recommended two years ago. It is obvious that a small service like the Indian Medical Service cannot cope with plague in India at its present dimensions. Those employed perform their duty with courage, skill, and devotion—indeed, with a blend of those qualities which should make us proud of the service; but if the whole of that service and also the whole of the Royal Army Medical Corps in India were detached from their civil and military duties and put on plague work they would be insufficient to deal with the present epidemic. A special service commensurate with the situation must be created to carry out inoculations and other plague measures. When that service is created and properly directed it is to be hoped that there will be an end to the policy which has discarded responsible medical advice since plague began and which has been so detrimental to the true interests of India. A special plague service will cost money, but it will be conceded that better use could not be made of a portion of the surpluses in the Indian revenue. For the past nine years there have been exceptionally large surpluses. Economy cannot be pleaded; motives of humanity insist that a vigorous attempt to deal with the appalling loss of life in

India should be forthwith set on foot; we do not attempt to speak with the exceptional knowledge of statesmen, but it seems to us that every thoughtful citizen will agree that motives of political expediency call as loudly as those of humanity for action.

The Control of Super-normal Arterial Pressure.

A valuable paper read before the Therapeutical Society on April 16th and published in The Lancet of May 18th by Dr. George Oliver on Some Notes on the Control of Super-normal Arterial Pressure affords an interesting example of the useful application of established physiological principles to secure a rational treatment of a persistently high blood pressure. Dr. Oliver has been a pioneer in the study of the blood pressure in man and his researches, together with those of many other observers, such as L. Hill, Riva Rocci, C. J. Martin, Clifford Allbutt, Janeway, and Erlanger, have definitely established the hæmomanometer as an instrument of precision, affording information which it is impossible to acquire by the *tactus eruditus* of the most educated finger. In one of the most evolved forms of the instrument, that of Erlanger, not only are the systolic and diastolic pressures shown but a graphic record is obtained which can be preserved permanently. But while an instrument of such complexity is only available for research in laboratories or in the clinical wards of a hospital the smaller and more portable forms are of great service in ordinary practice and are daily becoming more widely employed. Dr. Oliver's long experience of the method and the use which he has made of it to study the effects of treatment in the cases observed by him render his remarks of special interest and of unusual value, for he has made a special study of the effects of treatment directed to a specific object—the reduction of permanently raised blood pressure,—and shown his results in a form that admits of ready recognition—viz., the effects upon the actual pressure recorded. At the outset Dr. Oliver points out that a rise of blood pressure may be temporary or permanent, in the former case being produced usually through nervous influences, either psychical or reflex, while in the latter it is due to some alteration in chemical composition of the blood plasma or to some organic changes in the circulatory apparatus. Since with our present knowledge the discovery of the ultimate etiological factors in the genesis of high tension may be difficult or impossible, treatment has of necessity to be largely symptomatic—i.e., directed towards lowering the blood pressure by the various measures available where it is not possible adequately to combat the fundamental cause of the rise.

Diet in its relation to cases of super-normal pressure is first considered and since the origin of many cases is intimately associated with errors of diet continued over long periods, this forms a most important part of the treatment. Dr. Oliver enunciates the general principle that "we should reduce as much as possible not only the bulk of each meal but also the proportion of those constituents of the foodstuffs which more particularly stimulate the cardiovascular apparatus, such as various salts, soluble extractives, active principles, and other bodies—e.g., alcohol—which are directly absorbed without change and may be regarded as exogenous hormones between the digestive tract and circulatory apparatus, stimulating the heart on the one hand and the capillary circulation on the other." He recommends a reduction of the ordinary diet as a whole with a diminution in the animal and an increase in the vegetable food material. It is generally admitted that the supply of meats of all kinds should be limited. Dr. Oliver finds in addition that the manner of cooking is of more importance than the kind of meat taken; he recommends boiling instead of roasting or frying and excludes any substances likely to contain extractives, such as meat soups and gravies. With regard to fluids, the quantity taken at meals should be restricted to lessen the bulk of the material taken in, but they may be taken more freely when the stomach is empty, especially in the form of soft non-aerated waters; while it is wise to avoid hard water owing to the calcium which it contains. Tea and coffee in moderation are not banned unless their use is followed by dyspepsia or wakefulness. On the other hand, in the case of alcohol it is recommended that, although in slight cases small amounts may be permitted, yet as a general rule it is better avoided. The relation of sodium chloride to the diet of cases of super-normal pressure is carefully examined in the light of the views of Widal and Javal on "dechloridation"—viz., that in conditions of impaired renal permeability the retention of chlorides may lead to a retention of water with œdema and, albuminuria which can be relieved by dechloridation. Dr. Oliver is not prepared to recommend this procedure except as a temporary or experimental measure, since a saltless diet (which requires more than the mere omission of salt as a condiment) soon becomes distasteful to most patients. Some interesting observations on the effects of tobacco smoking upon arterial pressures are recorded, and since both in normal persons and in those with high arterial tension smoking produces a definite rise of systolic blood pressure it is undesirable for those with persistent high tension to indulge in that habit if they can be persuaded to avoid it. An interesting discussion of rest and exercise is given and the value of rest in the treatment of high-pressure cases is emphasised. It is pointed out that it is the best sedative of increased ventricular action, wherefore periods of absolute rest are enjoined, varying from a day once a week to three or four weeks at a time. On the other hand, moderate exercise, well within the limits of the patient's capacity, is doubtless of value in many cases, but here great care and judgment require to be employed; all violent exercise, all sudden exertion, and effort of any kind shortly after meals are to be avoided. Balneological treatment is regarded as of value but not to be relied upon as the sole means of treatment. Dr. Oliver recommends warm massage douching, such as the Aix-les-Bains douche, followed by the needle bath of alternating temperature and warm pack. He has also observed a beneficial effect with the D'Arsonval current applied for a few minutes daily, and certain French observers have recorded a persistent fall of pressure of as much as 60 millimetres of mercury from this treatment—a result which Dr. Oliver has not been able to confirm. The care of the skin is recommended so as to maintain the cutaneous circulation as effectively as possible, hence warm woollen clothing should be worn and warm climates visited, especially during the winter months, and an occasional Turkish bath with efficient massage may be taken. Venesection, apart from its employment in uræmia and cerebral hæmorrhage, is but little used in these cases and Dr. OLIVER asks whether it may not be used sometimes as a means of rapidly lowering pressure now that the hæmomanometer is able to afford the information enabling the right cases for the procedure to be selected.

Lastly, medicinal treatment is considered. This should be directed, on the one hand, to secure free evacuation and correction of the liver and bowels and to obtain gastro-intestinal antisepsis; and, on the other hand, to produce vascular dilatation and control of the vaso-motor apparatus. Some useful hints in regard to these various measures are given. The methods of giving purgatives are described and the use of various intestinal antiseptics is suggested, including benzo-naphthol, salol, salacetol, and tylmarin. The use of cardiac depressants is strongly and rightly deprecated but drugs varying the calibre of the arteries are recommended. Among such substances, thyroid extract has been found of value but it must be given with care and not as a routine treatment. It is interesting to find that the iodides which are so much used in the treatment of cases with high arterial pressure do not reduce those pressures. Dr. OLIVER has devoted some attention to the salts of the plasma and their relation to high pressure; he recommends the use, among other substances, of alkalies, the nitrate, nitrite, and carbonate of potassium, and also hippurates and benzoates of ammonium. He finds in general that cases vary considerably in their response to treatment and also points out that the high pressure may in certain instances be, in a sense, compensatory and therefore in such a case a necessary evil.

While there is nothing original about the treatment indicated by Dr. OLIVER his paper is a suggestive and useful one, because it sets forth the results of a careful examination of old remedies in the light of recent research, and in so doing it affords a useful guide in the employment of these drugs or measures and serves to emphasise the value of the hæmomanometer not only for purposes of diagnosis but also to gauge the results of treatment.

Meat and Tuberculosis—Some Reflections

THE mental digestion of the English people is generally regarded as being a somewhat slow but relatively sure process and at this moment the public mind is, as it were, ruminating over the last report of the Royal Commission on Tuberculosis, from which it must be inferred that the danger to the human subject from the ingestion of the tubercle bacillus of bovine type is a very real one. In THE LANCET of April 27th we dealt with what may be termed the human side of this great tuberculosis problem. We now propose to turn to other aspects of the question. Generally, the medical officer of health and the public are appreciating the fact that the last word upon the control of tuberculosis is not likely to be uttered while the discussion is limited to sanatoriums and sputum; indeed, there are some indications that possibly the evidence of the near future may suggest that the major danger may obtain in connexion with our milk supplies. Be this as it may, it is refreshing for the moment to turn from the injunction "*Ne crachez pas*" to some relatively new reflections if only because they raise points of very far-reaching influence and magnitude. Situated as we are in a small sea-girt island we are unable to feed our population of some 44,000,000 with home produce alone. Consequently, a very large amount of food which is capable of bringing with it the tubercle bacillus is borne, and will continue to be borne, to us across that silver streak which is at once our safeguard and our peril. From almost all parts of the habitable globe there converge towards our shores supplies of meat, of butter, and of cheese, all of which is, at least theoretically, capable of infecting us with tuberculosis. To cut off these supplies would mean starvation; to control them, in so far as tuberculosis is concerned, may prove difficult, more especially where foreign countries are in question. It is conceivable that in the case of our colonies some system of Imperial control might be devised but here we encroach upon the danger-line of politics and we will leave it to political organisations to paint pictures of a great non-tuberculous federation, fellowship with which shall mean the compulsory application of the tuberculin test to all cattle within its confines and the immediate destruction of all such as react.

Our object in this article is a less ambitious one and we must be content by the light of two reports which have recently been published, the one by Dr. W. COLLINGRIDGE, medical officer of health of the City of London, and the other by Dr. H. E. ARMSTRONG, medical officer of health of Newcastle, to deal with certain issues which are now pressing for serious consideration. Referring to the subject of the meat delivered in the Central Meat Market, Dr. COLLINGRIDGE points out that there is a decrease not only in the home-grown but also in the American meat killed in this country, these two sources of supply comprising some of the best meat. There is, however, so far as the Central Meat Market is concerned, an increase in dead meat from Australia and from North and South America, from which places, we are told, butchers who sell low-priced meats are mainly supplied. Dr. COLLINGRIDGE regards it as probable that this tendency will continue, as he thinks that the growing population of America will more and more absorb the finest produce of that continent. The Canadian supply, "though it can hardly be said that there has been improvement in its quality," is apparently increasing and the report before us expresses the opinion that before long the magnitude of the Canadian supply will render this country independent of the United States. In the meantime we are threatened with carcasses from Roumania and from Mexico and the diminution of home-grown meat passing through the Central Market brings the proportions of British and sea-borne meat as 1 to 4. As regards the quality of the United States beef Dr. COLLINGRIDGE speaks highly but he is evidently far less satisfied with much of the pork which reaches this country in a condition which renders inspection carried out on arrival almost valueless. The importation of Chilian and Argentine beef is greater than ever and any break in the supply disorganises the market. The supply of New Zealand beef is steady and that from Australia shows an increase. Pigs from Australia are, generally speaking, good but many of those from Argentina prove to be tuberculous. Now the meat coming from the Argentine Republic, Belgium, Denmark, Holland, New Zealand, and the United States of America bears labels indicating inspection before exportation and it appears that, owing to efforts made by the City Corporation, the quality of this inspection has recently undergone material improvement.

The question, however, arises as to what is the real value of this foreign inspection as compared with a rigid system in this country of inspection of the cattle both before and after slaughter in properly controlled abattoirs and it is probably with the object of bringing this point into prominence that the corporation has determined to abolish the private slaughter-houses at the markets under its control at Islington and to erect a public abattoir. Dr. COLLINGRIDGE advises that all meat slaughtered there and found to be wholesome shall be so marked as to be recognised and appreciated by the public and he thinks that this procedure would greatly promote the interests of the British agriculturist. Certainly the proposal is one which should meet with support on grounds of public health alone and the economic aspect of the scheme is accentuated by the fact that at the Central Meat Market the proportion of British country killed meat has fallen from 22·7 per cent. in 1903 to 17·2 per cent. in 1906, while that of British town killed has declined from 6·8 per cent. to 3·4 per cent. during the same period. In these circumstances it is obviously unscientific to adopt in regard to home produce severe restrictive measures while allowing foreign produce to obtain entry even although a label be attached indicating what may sometimes be little other than a perfunctory inspection, and Dr. COLLINGRIDGE is taking a wise course in limiting his recommendations to the practicable. But a moderate programme such as this will not, we gather, satisfy Dr. ARMSTRONG who has recently compiled a somewhat remarkable report upon the subject of tuberculosis. In his view bovine tuberculosis should be eliminated from all British cattle by means of the compulsory application of the tuberculin test, all reacting animals to be "forthwith sterilised and destroyed." With the German "Freibank," an institution wherein the carcasses of certain tuberculous cattle are rendered sterile and sold at a low price to the poor, Dr. ARMSTRONG will have nothing to do. The 22,758 tuberculous carcasses found in the abattoirs of Saxony, and 92·5 per cent. of which were passed as fit for food, should have all been destroyed as the "doctrine of tuberculosis at any stage being 'localised' is false and mischievous and should be utterly abolished." Dr. ARMSTRONG does not, however, deal adequately in this very comprehensive scheme of his with the vast supplies of meat which reach us annually from foreign countries and from our colonies but it is this point which should in our view be frankly faced by all those who profess seriously to consider the problem of tuberculosis. The element of practicability must not altogether be lost sight of and the proposal to place our home produce under all sorts of restrictions while admitting freely all foreign dead meat is not one which can be seriously put forward with the view to its adoption at the present time. The compulsory provision of public abattoirs, the increase of competent meat inspectors, and the closing of private slaughter-houses are much more likely to receive the support of the nation.

Annotations.

"Ne quid nimis."

MEDICAL OFFICERS AND THE WORKMEN'S COMPENSATION ACT.

THE Workmen's Compensation Act, which is to come into force on July 1st next, will, whatever else it may do, certainly provide employment for the legal profession. As regards our own more immediate interests we may consider the question of the position of medical officers of health, of medical officers under the Poor-law, and of resident medical officers in a hospital. The Local Government Board has issued a circular to various local authorities stating that "it appears to the Board that local authorities generally will be employers within the meaning of the Act," and that they may properly incur reasonable expenditure in effecting an insurance against their liability. If local authorities are employers what is a "workman"? The circular quotes from the Act as follows:—

> "Workman" does not include any person employed otherwise than by way of manual labour whose remuneration exceeds two hundred and fifty pounds a year, or a person whose employment is of a casual nature and who is employed otherwise than for the purposes of the employer's trade or business, or a member of a police force, or an out-worker, or a member of the employer's family dwelling in his house, but, save as aforesaid, means any person who has entered into or works under a contract of service or apprenticeship with an employer, whether by way of manual labour, clerical work, or otherwise, and whether the contract is expressed or implied, is oral or in writing.

As regards the salary limit it is certain that many members of the three classes to which we have referred come within it and it would therefore seem as if all of them would have the right of compensation under the Act for injuries incurred in the course of their employment; such, for instance, as an infected wound received during the making of a post-mortem examination, injuries inflicted by a lunatic patient, or an accident received while riding, driving, or travelling in or on any form of wheeled vehicle to visit patients. We have raised the point as it is undoubtedly an important one for the medical profession, but the wording of the Act appears to be capable of interpretation in so many different ways that only a judicial decision will be able to settle the many vexed questions which will assuredly arise. And this is the reason why we press upon all our readers the necessity of insuring against the risks of the new legislation. It is certain that an enormous amount of claims will be made under the Act, and those who are insured will be free from all legal responsibility. Many of the claims may not prove to be good ones, but the uninsured medical man must none the less spend money in disputing them. The scheme to which we have promised support, under which the Guardian Assurance Company, Limited, offers exceptionally favourable terms to those insuring through the Medical Insurance Committee, bids fair, we believe, to be a success, and we cannot give our readers better practical advice than that they should make application to the committee, care of the British Medical Association.

THE ADVANCING WAVE OF EDUCATION.

THE increasing interest shown by all classes of society in regard to education will have far-reaching consequences in our social history. The need for a wider knowledge of educational matters is showing itself in many ways, some of which we indicated in a recent leading article dealing with school hygiene, and the intimate connexion of the health of the people with their instruction was further illustrated at the Imperial Conference. Important meetings were held while the Imperial Conference was in session at the City Guildhall and at the Examination Hall of the Conjoint Board of the Royal Colleges, the object of the first being to consider education in relation to the Empire, and of the second to deal with the teaching of hygiene and temperance in the universities and schools of the Empire. Some echo of these proceedings must reach every part of the globe. At the Guildhall meeting Lord Milner emphasised the necessity for our youth to realise the greatness of their privilege in being potential citizens of every community over which the British flag flies, so that in going to, or in coming from, any of the colonies they were not going to or coming from a strange land but merely passing "from home to home." How far Lord Milner's ideal will become an actual fact depends largely upon the developments of medicine in the near future. The word "home" means something more than a place where the individual can live and work: it must for one thing mean a country where health is not at a premium. Unfortunately, there are still many places in our Empire where only the most robust can hope to withstand the unfriendliness of the climate. Medical science has already done much to render inhabitable parts of the world where the white man could not possibly find a home in the real sense of the word, but much more requires to be done in this direction and will be done if medicine receives adequate public support. At the meeting held in the Examination Hall, on the motion of Sir Lauder Brunton, a resolution was adopted to the effect that it was essential that a medical department should be instituted in the Board of Education, and no course could be better devised for bringing home to the mass of the people the debt owed by all to scientific medical service. How this is to be accomplished remains to be settled, but the association of medical science with the machinery of teaching must work for good. When the Second International Congress of School Hygiene has finished its labours in August next, it is to be hoped that the experience of educational authorities garnered from every part of the civilised world will point to the importance of associating medical science with the details of education. A practical outcome may be the result, for the country is expecting some movement along the right lines.

THE CHEMICALISED ROAD.

It has been freely stated that wherever a solution of calcium chloride has been sprinkled on the roads the result invariably has been success, for in spite of a busy motor traffic not only was there no dust raised immediately after application of the fluid but apparently the dust-preventive effect was permanent. This sounds like the consummation everybody must desire and the end of the great and exceedingly serious dust problem. We should like to think that such was really the case, for this nuisance is inflicting hardships on all sides, it is seriously damaging property, and it is a real menace to the health and well-being of the community. Ample proof that many minds are convinced of the efficacy of the calcium chloride treatment is seen in the fact that several of the authorities who are responsible for the good condition of the highways are entering into contracts for the supply of this salt. The time may soon come, therefore, when the roads throughout the country will be systematically and periodically dosed with solution of calcium chloride in order to prevent the colossal dust nuisance created by motor traffic. For one thing calcium chloride is cheap enough and the supply is not likely to run short, since it is a waste product of certain great technical operations. The *rationale* of the method is easy enough to understand; the road material sprinkled with calcium chloride solution is converted more or less into a permanently moist state on account of the hygroscopic property of the salt. It would be rash to assert that such a process is going to stand the test of time. We have yet to learn what effect such treatment is likely to have upon the road surface after weeks, months, or years of application. It will also be important to find out whether calcium chloride proves to be free from corrosive properties. Will it affect the foot of the horse, sheep, or oxen? Will it attack the rubber tyre? Will splashings containing calcium chloride corrode clothes, the skin, woodwork, and so on? Perhaps also some risk may be involved by inhaling a dust impregnated with an irritating salt. As is well known, a solution of calcium chloride practically acts as an acid and readily attacks iron and other metals, so that it is possible that the use of calcium chloride as a dust preventer on the roads may prove to be a remedy worse than the disease. A shower of rain, of course, is calculated to wash out the calcium chloride, so that the moment dry weather succeeds wet the application of the salt would have to be renewed. The idea of applying hygroscopic chemicals to the road is by no means new—it was tried many years ago in the simple shape of sea-water; but we believe that it was abandoned because the road after such treatment showed signs of irregularities and road engineers were strongly of opinion that the practice should be discontinued. Moreover, complaints arose that roads watered with sea water had an injurious action on the horses' feet and on the tyres and fittings of vehicles. It is to be feared that the calcium chloride method of treating roads for the prevention of dust will not turn out to be the simple solution which it seems. We should rejoice with the multitudes if we could feel any justification for taking the opposite view and see any prospect of the abatement of this great modern plague.

MELÆNA NEONATORUM.

In the present issue of THE LANCET Dr. J. Basil Page records a very interesting example of the rare condition known as melæna neonatorum. In this particular case the blood was vomited as well as passed in the motions, but the child ultimately recovered. More commonly the bleeding leads to a fatal issue and the mortality is a very high one, varying from 35 to as much as 50 or 60 per cent. The onset is usually within the first week of life and the child is often found to be jaundiced, as in Dr. Page's case. Numerous theories have been brought forward to account for this interesting condition. It has been attributed to the effect of traumatisms occurring during or after birth, but injuries to the newly-born child are not uncommon, while melæna neonatorum occurs but once or so in 500 or 600 infants. The fact that various forms of septic infection of the fœtus are often accompanied by a tendency to hæmorrhage has been supposed to point to a septic causation of these cases; unfortunately, as Ballantyne points out, the numerous varieties of organisms which have been described as present do not lend much weight to this view. One of the most interesting and ingenious theories is that which regards the cause as due to some disturbance in the normal readjustment of the circulation at birth. The fact that not infrequently ulcers are met with in the duodenum or stomach is regarded as further evidence. It is argued that small emboli are carried from a thrombus in the umbilical vein to some of the small arteries in the stomach or intestinal walls, where they produce local death of the tissues and the consequent formation of small ulcers. This view does not, however, explain the rarity of this form of melæna when we remember the frequency with which such vascular disturbances occur. Still another view is that the disease is due to some factor acting in the antenatal period of fœtal life. May it not possibly be a manifestation of hæmophilia or of purpura, or may it not be one of the many pathological conditions produced by the virus of congenital syphilis?

The multiplicity of theories reveals our real ignorance of this condition and we are therefore not in a position to take any measures to avoid its occurrence. Treatment is hardly possible when the hæmorrhage occurs in a newly-born child; however, the internal administration of one of the preparations of suprarenal extract might be tried or the hypodermic injection of a 2 per cent. solution of gelatine. The injection of 15 centimetres of such a solution, which had been boiled for six hours and allowed to cool to about 100° F., was followed by recovery in five consecutive cases in the hands of one observer.

THE MILK-SUPPLY OF THE CARDIFF INFIRMARY.

The secretary of the Cardiff Infirmary has forwarded us a copy of the tender for milk required from contractors by his committee, the clauses of which are of such praiseworthy severity as to guarantee a pure milk-supply to the infirmary. They deal with the cows, and the storage, transport, and quality of the milk. The cows are to be examined and certified healthy by a veterinary surgeon selected by the infirmary and are to be milked in a clean and dustless place after their udders and the hands of the milkers have been washed with soap and water. The milk is to be strained and cooled to at least 50° F. immediately and delivered at a temperature of not more than 52° in "churns" belonging to the infirmary which are always to be kept locked except for filling, emptying, and cleaning. The milk is to be delivered without delay, is not to contain any "preservative" or colouring matter, and must conform to the chemical standard of the Sale of Food and Drugs Act. The farm is to be open to inspection at any time by the representative of the infirmary and must be within 15 miles of that institution. Before the tender is accepted the sanitary adviser of the infirmary is to certify that the conditions laid down can be met by the contractor's arrangements and any breach of these conditions will at once terminate the contract. We are informed that "the form is in force with satisfactory results," and this excellent example might be with advantage widely followed

EXTENSIVE NERVE INJURY FROM REMOVAL OF CERVICAL GLANDS.

In the *Boston Medical and Surgical Journal* of May 2nd Dr. J. W. Courtney has called attention to a serious accident in removal of cervical glands—extensive nerve injury. In searching for glandular débris behind the sterno-mastoid the spinal accessory or cervical or brachial plexus may easily be injured with disastrous results Three cases are reported by Dr. Courtney. In the first case the patient was a man, aged 52 years, who was seen on Nov. 30th, 1906. On Sept. 1st some enlarged glands were removed from the right side of the neck in a hospital. On recovery from the operation he noticed that the right side of his neck drooped. After three weeks he resumed his occupation as a barman, suffering from pain in the right shoulder and side of the neck and weakness of the arm. On examination the shoulder drooped markedly and the muscles above and below the clavicle were atrophied. Along the inner border of the right sterno-mastoid was a scar three inches long, the result of the operation. The right sterno-mastoid muscle seemed to have disappeared. The right arm could not be raised from the body above an angle of 40°, but the deltoid did not seem particularly atrophied. The right pectoral muscle was markedly wasted. The left grip was 100; the right only 75 (the patient was right-handed). Electrical changes in the affected muscles were only quantitative and were in proportion to the degree of atrophy. Evidently the spinal accessory and cervical plexus were seriously injured and a secondary neuritis had been set up in the brachial plexus. In the second case the patient, a girl, aged 19 years, was seen on April 27th, 1904. Five years before glands were removed from the left side of the neck without untoward result. Eight months before glands were removed from the left side of the neck. On recovering from the anæsthetic she found that the left shoulder was very weak and that she could not raise the left arm at all. There was also considerable pain in the neck which prevented her from turning her head. After two weeks she tried to resume her occupation of stenographer but had to desist as the left hand was useless. Examination showed considerable atrophy of the left shoulder girdle. The scapula was everted and rotated forward. Electrical examination revealed quantitative diminution to faradism in the left trapezius. The other muscles appeared to react normally. The patient was not seen again until Feb. 17th, 1907, when the left side of the neck had lost its fulness and there were marked supra- and infra-clavicular depressions. The cervical border of the left trapezius was markedly thinned. The supra- and infra-spinatus muscles were slightly atrophied and the rhomboids more so, approximation of the scapula to the spine being seriously hampered. The affected muscles showed only quantitative loss to faradism. She had resumed her occupation but the left arm and shoulder soon became tired. In the third case a boy, aged 13 years, was seen on Oct. 24th, 1906. Five years previously glands were removed from the right side of the neck. After the operation his mother thought that he was growing round-shouldered. Examination showed marked shoulder-drop on the right side, supra- and infra-clavicular depressions, thinning of the cervical border of the trapezius, considerable wasting of the pectorals, some atrophy of the supra- and infra-spinatus, and eversion and forward rotation of the scapula. The right arm could be raised fairly to a right angle but beyond that with difficulty. All other movements of the arm and hand were weak. Movements of the head and neck were limited on the right side. The right scapula could not be approximated to the spine. The affected muscles showed varying degrees of quantitative loss to faradism. Four months' treatment by massage and electricity produced little benefit.

THE MEDICAL SERVICE OF THE NILE RESERVOIR WORKS.

Dr. J. Ferguson Lees, the senior medical officer of the great reservoir works which Messrs. John Aird and Co. are carrying out at Isna, has forwarded the report to his company dealing with the medical arrangements of the Isna Barrage. The provisions for employees suffering from accident or disease appear to be in every way worthy of the splendid engineering scheme with which they are connected; in January last, from which month this report is dated, the daily average of men employed on the works was 7843, of which number 88 were Europeans and 7755 were natives. A completely equipped hospital has been erected capable of accommodating 18 Europeans and 16 natives, the blocks for these being separate. The European wards are of three classes, capable of accommodating from one to four patients respectively, and there are two native wards for eight patients in each; an out-patient department with a branch building on the opposite bank of the river is included in the scheme. In various parts of the works tents have been erected as dressing stations, with first-aid appliances, and so complete is the equipment that during the summer months certain of these will be provided with baths and ice-boxes for the immediate treatment of cases of sunstroke. The description of the hospital buildings shows them to be well suited to the local conditions; a complete operating theatre has been provided, for which there is an evident need, as appears in the analysis of the cases treated. Dr. Lees reports that the fellaheen come in for treatment when suffering from accident far more readily than they do for sickness, as in the latter case they still have more confidence in the skill of the native barber than in the methods of European medicine. The subordinate staff of the hospital consists of a native head ward orderly, with five trained native orderlies who do the nursing, two cleaners, a cook, a gardener, and a laundry woman, the whole being under the charge of an English head attendant and storekeeper; when special nursing is required English nurses are obtained from Cairo. The report states that the bulk of the cases is formed by "injuries, ophthalmia, dysentery, and diarrhœa, with catarrhal affections of the respiratory system in the winter, and febrile conditions due to the heat in the summer months." The preventive work has been excellently organised; the best water- and food-supplies obtainable have been installed, the meat is inspected before and after slaughtering, and there is a laboratory for the analysis of other articles of diet. There is a plentiful supply of Berkefeld filters in the hospital. A system of moveable latrines and sewage trenches is under the control of a sanitary inspector and as a result of these careful precautions the medical officer is able to state that "the general health of the camp during the period covered by the report has been good." In the event of an outbreak of infectious disease it is proposed to erect mud shelters for treating cases, which can be destroyed when no longer needed.

THE COÖPERATION OF LOCAL SANITARY AUTHORITIES.

ON May 18th a meeting of representatives of certain county councils and urban sanitary authorities was held at Newcastle under the presidency of Alderman H. W. Newton, chairman of the sanitary committee of the Newcastle corporation. The meeting considered the report of Dr. H. E. Armstrong, medical officer of health to the corporation, on the problem of tuberculosis, and in the course of a valuable address on the urgency of meeting it efficiently the chairman brought forward a motion which embodied these proposals:—

> That in the opinion of this meeting it is desirable that a permanent union of the sanitary authorities of England and Wales be established as a supreme national health authority, with the object of safeguarding and promoting the public health interests of the people at large against tuberculosis and other dangers to the public health.

This motion was unanimously adopted by the meeting which then constituted itself a committee for the furtherance of this object with power to add to its numbers, and the chairman announced that the coöperation of all the sanitary authorities in the country would be invited in the interests of the scheme. We consider that this movement is on the right lines and we welcome its inception; it seems desirable that an organisation of sanitary authorities may be formed with a view to winning statutory recognition and of paving the way to the foundation of such a truly national health service as can alone face such gigantic problems as those presented by tuberculosis.

THE ETIOLOGY OF ACUTE PANCREATITIS.

THE etiology of acute pancreatitis is still a moot subject. Dr. A. Egdahl has contributed to the *Johns Hopkins Bulletin* for April an important paper consisting of an analysis of the reported cases in which the cause of the disease is stated or suggested. These amount to 105. The preponderating cause assigned is gall-stones which are supposed to act by causing obstruction to the flow of bile and its retro-injection into the pancreatic duct. Gall-stones were the assigned cause in 44 cases. The next most common cause was gastro-intestinal obstruction which was recorded in 32 cases. It is noteworthy that in 17 of these cases there was gastro-duodenitis due to alcohol or with a history of alcoholism. In two cases the pancreatitis followed an attack of appendicitis but the nature of the connexion cannot be stated. Two cases were associated with typhoid fever. In one a patient who had recovered from typhoid fever was seized with fatal pancreatitis. In the other case repeated inflammatory disturbances of the pancreas followed recovery from an attack of typhoid fever and typhoid bacilli were demonstrated in the bile. Pancreatitis is a rare but well-recognised metastasis of mumps—one to be expected when the similarity of the pancreas to the salivary glands is remembered. Of 652 cases of mumps treated at the hospital of Val-de-Grâce Simonin has reported that pancreatitis occurred in ten. One case each of pancreatitis has been attributed to boils, malaria, gastric ulcer, duodenal perforation, syphilis, and tuberculosis. Two cases have been attributed to embolism of which one was fatal. Three cases have been ascribed to trauma. The immediate cause of acute pancreatitis appears to be infection of the duct of Wirsung. The bacillus coli and other pyogenic organisms have been found in the pancreas. Mr. A. W. Mayo Robson thinks that in the cases of retro-injection of bile the inflammation is due to organisms carried in that fluid. In cases of injury to the pancreas a condition favourable to bacterial invasion is obviously produced. Infection may also occur through the blood stream.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: THE ORIGINAL NOTES OF JOHN HUNTER'S LECTURES.

THE recent presentation by Dr. Thomas James Walker of Peterborough to the Royal College of Surgeons of England of the *original notes of John Hunter's lectures*, taken by the latter's pupil Mr. Hopkinson, is an interesting addition to the College library. In a letter sent to the College with the volume Dr. Walker explains how the book came into his possession. He says: "A hundred years ago Mr. Hopkinson was carrying on the practice which, with Dr. Kirkwood and my son, I now conduct. Mr. Hopkinson was succeeded by Mr. Whitsed, who in 1819 sold the practice to my father, Thomas Walker. After introducing my father, Mr. Whitsed went to Edinburgh, took his M.D. degree, and for a time settled in London; afterwards he moved to Wisbech, where he practised as a physician and died in the early 'sixties.' After his death the book remained in the hands of his daughter for several years and by her it was given to me." At the commencement of the volume is an original letter from Mr. Clift, the conservator of the College, dated Sept. 16th, 1835, to Mr. Whitsed concerning the volume, and a cutting from the *Englishman* newspaper, dated Nov. 9th, 1836. These additions add greatly to the interest of the gift and are to be retained in the volume at the request of Dr. Walker. The cutting from the *Englishman* is a statement concerning John Hunter's papers and manuscripts and a reputed conversation—"on the road to Kew"—between Sir Everard Home and Mr. Clift regarding the manuscripts. As announced in THE LANCET last week, the presentation was made to the College by Dr. Walker in commemoration of the completion of the fiftieth year of his Membership of the College.

EPIDEMIC CEREBRO-SPINAL FEVER.

IN the districts where epidemic cerebro-spinal fever is prevalent the number of cases have shown no great change during the last seven or eight days. In Scotland during the week ended May 18th there were 23 deaths from this cause registered in Glasgow, 7 in Leith, 5 in Edinburgh, 2 in Dundee, and 2 in Paisley. In Glasgow the weekly report issued on May 17th showed that there were at that time 125 cases under treatment. It is announced that in Edinburgh during the month of April 43 cases were notified and 36 deaths occurred. In Belfast during the week ended

May 18th there were 21 deaths from this cause registered; in this city there has now been a total of 420 cases and 295 deaths, 43 cases remaining under treatment.

THE ESTIMATION OF SUGAR IN URINE BY MEANS OF CAUSTIC ALKALI.

IT is well known that when a solution of glucose is heated with a solution of caustic soda a yellow or brownish yellow colouration develops. Apparently the intensity of the colour is directly proportional to the amount of sugar present. This has suggested to Dr. Wladyslau Swiatecki of Warsaw the employment of caustic soda as a reagent for the estimation of sugar in urine. For this purpose he takes, according to a note which he has sent us, two glass tubes of the same dimensions and places in the one from five to ten cubic centimetres of a 1 per cent. solution of grape sugar in distilled water and in the second the same quantity of urine. To each are then added some drops of concentrated solution of lye (caustic soda) and the mixture then boiled for a few seconds over the flame of a gas or spirit lamp. After cooling, the boiled urine is filtered from the deposited phosphates. To the filtrate, the volume of which is noted, distilled water is added until the colour matches the sugar solution treated in the same way. The comparison is best made in daylight, the tubes being placed on white paper. From the difference between the quantity of urine before and after dilution it is easy to calculate the percentage of sugar. If, for instance, the quantity before dilution was equal to six cubic centimetres and after to 18 cubic centimetres the urine contains $\frac{18}{6} = 3$ per cent. of sugar. If, on the other hand, the urine is not so deep in colour as the standard solution of sugar the latter is diluted and the calculation made accordingly. Dr. Swiatecki admits some inaccuracies in the process, but states that with care the results are trustworthy. As he points out, normal urine is of a yellow colour and as the reaction of sugar with alkali leads to a yellowish colouration this would vitiate the result. He suggests, however, that diabetic urines are for the most part very pale and almost colourless. If that is not the case he takes the precaution of decolourising the urine by passing it through charcoal. Another source of error is that normal urine assumes a dark colour with caustic alkali owing to the occurrence of nucleo-albumins. These should be removed by lead acetate. The results, he states, are more or less accurate and compare favourably with other colorimetric processes or with Fehling's method or that in which the polarimeter is used. The method has the merit of simplicity, while it takes little time to perform.

STERILE PURIFORM MENINGEAL EFFUSION WITH INTACT POLYNUCLEAR CELLS.

AT the meeting of the Académie de Médecine of Paris on April 30th, M. F. Widal and M. A. Philibert pointed out that a puriform effusion is not, as is generally supposed, necessarily septic. In the great majority of cases a puriform appearance is evidence of microbial origin, but sometimes the fluid may remain sterile from its appearance until its absorption. The difference is important, because the prognosis of aseptic pus is much better than that of microbial pus. A cytological difference between these two kinds of pus has been found both in pleural and meningeal effusions. In microbial pus the polynuclear cells, damaged in their struggle against microbes and their toxins, present characteristic changes in their nucleus and protoplasm; in aseptic puriform effusions, on the other hand, the polynuclear cells are intact. In the following case of supposed cerebrospinal meningitis the integrity of the polynuclear cells enabled M. Widal and M. Philibert to pronounce the effusion to be aseptic and to give a good prognosis. A youth, aged 17 years, in good health, suffered from malaise, lassitude, and severe headache on Dec. 28th, 1906 (when influenza was prevalent in Paris). On the following day he was worse and had also sore-throat. On Jan. 3rd, 1907, he was admitted into hospital complaining principally of headache and persistent insomnia. The temperature was 102° F. and the pulse was 76 and regular. Kernig's sign was present and the knee-jerks were slightly exaggerated. On the 4th lumbar puncture was performed. The cerebro-spinal fluid was under high pressure, gushed out in a jet, and was puriform. The headache immediately disappeared. Cultures and inoculation of a white mouse yielded no results. Centrifugalisation showed 68 per cent. of polynuclears, 14 per cent. of large mononuclears, and 18 per cent. of lymphocytes. All the cells were in a remarkable state of preservation; the contour of the nuclei and of the cytoplasm was clear. On the following day the temperature had fallen to normal, Kernig's sign was absent, and the patient felt well. On the 7th lumbar puncture yielded fluid containing principally mononuclears (88 per cent., with 6 per cent. each of lymphocytes and polynuclears). On the 16th the patient left the hospital quite well. At first sight the symptoms and the turbid and puriform appearance of the cerebro-spinal fluid seemed to impose the diagnosis of cerebro-spinal meningitis; but the integrity of the polynuclears showed that the fluid was aseptic. Similar transitory puriform effusions have been found in syphilis of the nervous system. They are also induced when an aseptic solution of cocaine, which is not isotonic with the cerebro-spinal fluid, is injected for the purpose of producing spinal anæsthesia. They have been observed in cases in which a distant focus of infection has acted indirectly on, and by means of toxins produced irritation of, the meninges. In the active period of syphilis meningeal lymphocytosis is frequent, but spirochætæ have never been found in the cerebro-spinal fluid. M. Widal and M. Philibert suggest that in the case related above the meningitis was due to influenza.

THE medical officer of health of the Cape Colony in a bulletin dated April 29th states that a male native living in King William's Town who died suddenly on April 22nd was after post-mortem examination found to have died from plague, and a female native living at the same address, admitted to the Grey Hospital, died from plague on April 27th.

WE deeply regret to announce the death at Falmouth on Tuesday last of Sir Joseph Fayrer, one of the most eminent Anglo-Indians of the Victorian era, and for 20 years President of the Medical Board at the India Office. A full notice of his distinguished scientific and official career will appear in our columns next week.

AT the next meeting of the University College Medical Society on Wednesday, May 29th, Mr. W. Bateson, F.R.S., will read a paper on the Study of Heredity. The chair will be taken at 8.30 P.M. by Sir Victor Horsley, F.R.S.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—On May 30th, at 5.30 P.M., a general meeting of this society will be held at 20, Hanover-square, London, W., to be followed at 6 P.M. by an address to be delivered by Dr. Norman Moore entitled "Air, Water, and Situation." At 7.30 P.M. on the same evening the annual dinner, to be followed by an entertainment, will take place in the Balmoral Rooms, Trocadero Restaurant, Piccadilly, when Dr. Norman Moore and Mr. W. Arbuthnot Lane will be guests of the society. The charge for the dinner is *7s. 6d.*, exclusive of wine, and Fellows of the society intending to dine are requested to inform the honorary secretary, Dr. S. P. Sunderland, 11, Cavendish-place, London, W., as soon as possible.

SANITARY AUTHORITIES AND SANITARY OFFICERS: A CRITICISM OF THE PRESENT MODE OF ADMINISTERING THE PUBLIC HEALTH ACTS IN ENGLAND.

By J. H. GARRETT, M.D. DURH., D.P.H. CANTAB.,
BARRISTER-AT-LAW; MEDICAL OFFICER OF HEALTH OF CHELTENHAM.

THE popular leaning in England has been for long towards a preference for the management of local matters by local councils. The idea of entrusting the local population with the management of its own concerns is tinted with a roseate suggestion of a larger freedom, but appears to be based upon the somewhat fictional supposition that every local population contains in itself the elements for its own proper ruling, and that these ruling elements are always available and sure of recognition and selection by the votes of the local electors. This, however, is by no means the actual case, and a further source of weakness is found in the extreme proneness shown by the members of local councils to prefer their own individual interests, whenever possible, to those of the public, which they are ostensibly elected to serve. The sanitary laws are administered at the present time by these local elective councils—the city and borough councils, the urban district councils, and the rural district councils—and it is convenient to speak of these as the sanitary authorities of the districts which they have been severally elected to govern. Upon these local elective councils some restraining influence, especially as regards expenditure, is exercised by a department of the general Government—namely, the Local Government Board. The county councils have also a few public health powers and the parish councils a few of a minor sort, which last are but very little exercised. There is, however, a growing tendency on the part of rural district councils to shirk the responsibility and trouble of deciding questions as to the provision of sewers, water-supply, housing accommodation, or what not, in the villages of the district, and to refer them for settlement to the councils of the parishes to which they pertain, following the prevalent theory that the local community, however small, is the proper one to judge of its own needs and to decide the desirability, or otherwise, of carrying out such sanitary works as those specified.

The continued division of authority incidental to the decentralising process is in several ways disadvantageous, since it tends to disintegrate interests which are common to large communities. It also leads to a difficulty in raising funds necessary for carrying out such works as may be badly required and in supplying that expert scientific guidance so essential for the appreciation of simple sanitary requirements by uneducated rustics. The narrow minds of rural councillors are always unduly affected by consideration of expense and by that conservative policy of let-be which permits of the fool's paradise in which they are usually so content to dwell. The capacity in individuals of ruling the mass of the populace with good effect is not a common one, and the smaller the district the less likelihood of its containing men capable of becoming effective rulers. Thus we have not to go so far down the scale as to parish councils before the proofs of marked incapacity become all too apparent in the acts and omissions of our local rulers, and, indeed, it seems that there are now more councils than available men endowed with any noticeable capacity for acting the part of councillors. In answer to this allegation it may be urged that it is unfair to take the mental capacity exhibited upon the council as representative of the best in the locality, and it must be at once admitted that the occupation of taking part in the management of local affairs is not ardently sought in any locality by the men of best education and widest intelligence and experience. In the exercise of the local franchise the electors give very slight attention to the suitability or otherwise of the candidate. His character or want of character stands for little. In the towns, whenever there is a contest between candidates, the election is generally run on political party lines, and otherwise is affected by a busy personal canvass accompanied in too many instances by a petty-cash bribery of a certain part of the poorer voters. The result is that many of the most able men in the community hold themselves aloof, declining to undergo the ordeal of such an "election" or to be associated with the men who by such means come on to the council. There is, however, never a plethora of candidates of any sort, and a large proportion of the elections, especially in the rural districts, being uncontested, practically anyone possessed of a little audacity may rise to the honour of becoming a local governor and an administrator of the public health laws.

Contemplation of the fact that expenditures will be followed by increase of rates often creates an opposition to the carrying out of necessary works. The tax may have to be contributed to by many who gain no benefit by the expenditure, for although special rating areas are sometimes permitted to be made for the recovery of the expenses of works which only affect such areas, it is often nevertheless impossible to limit the payment to those who enjoy the advantage. So it happens that the members of councils themselves from being large landowners or land occupiers in country districts, or from having extensive shop or factory premises in towns, will be hit hard in the matter of the increase of rates which must result from the carrying out of works or improvements intended to be of benefit to the health of the general community or some special part of it. Such councillors commonly exhibit a conservatism towards any proposed scheme which will lead to this taxing of themselves, or their reservation of support not infrequently grows into a strong opposition. Appearances may sometimes require to be saved on account of the evident advantage of the proposed work to the greater part of the populace, and the opposition is then apt to become cunning and covert. Powerful outsiders whose interests are affected in a similar way to those of the property-owning councillors often exert influence upon their friends upon the council, and the opposition thus becomes so considerable and continuous as not infrequently to delay for many years the introduction of the required provisions or reforms.

But a greater obstruction than that occasioned by fear of having to pay for works done for other people's advantage arises amongst individuals and classes of individuals when in the course of bringing into operation the several sections of the public health laws, their particular interests become so affected as to result in money loss. It is very common for the provisions which are intended to result in the advantage of the many to prove adverse to the financial interests of the few. Thus, whether it be a matter of preventing the sale of food substances, meat, milk, &c., when in a state dangerous or unfit for consumption, or of dealing in a radical and expensive manner with defects in house properties, or of restricting traders in the nuisances caused by certain offensive businesses, or by interfering in the conditions attending the conduct of labour in workshops, all leading to expense or diminution of profits for the trader, manufacturer, or property owner, the people who are thus adversely affected will oppose themselves to the putting into force of such provisions to as great an extent as they can, and this they often do effectively, either by themselves getting elected upon the councils or by exerting such influence as they are able upon those who are elected. Thus no sooner is it proposed to abolish private slaughter-houses in favour of the use of a public abattoir (a matter which affects the interests of butchers in more ways than one) than a posse of butchers get themselves elected on to the council and when a crusade against some crying abuse connected with small house property or any other property is started the property owner is at once on the alert and comes on to the council probably along with several of his friends and dependents. The ability and powers of comprehension of the general run and ruck of the council are always so extremely mediocre that when an eloquent and determined man comes amongst them he is able to impress them with astonishing facility and when his principles are honest and sound he becomes the central motive force by which the council can be led to good public work. The dominating personality, however, which is thus capable of such strong leading effect is not invariably characterised by soundness of opinion or honest disinterestedness, and this is unfortunate, because it does not cease on that account to have the same leading effect upon inferior minds which seem incapable of making distinction between good and bad, but follow the strong man blindly, or at best with only a confused appreciation of why they follow him. Thus the person who comes on to the council with the intention of guarding private or class interests, if he has sufficient power of self-assertion, including some gift of speech, will invariably be able to occupy the position where his power can be made most effective. He is sure to be placed upon the committee which deals with the business in which he is particularly interested and will very likely become the chairman of that committee. His self-assertion is aided by the muddled state of the understanding of the weaker members of the council rather than by their logical intention. It is quite a common thing for a person whose private interest should cause his rigid exclusion from a committee which regulates that interest for public advantage to be specially invited to join the committee on the ground of his intimate knowledge of the business. The abuses that arise from the overwhelming representation of private interest upon the local council appear inseparable from our present system of managing local affairs, but in sanitary matters they are more often operative than in any other branch of local government.

In view of the fact that public health work is of a highly technical character, and on account of the ignorance in regard to the work which is to be expected on the part of the members of local councils, the law requires every council that is in the position of a sanitary authority to employ a medical officer of health. The medical officer of health is the only officer of a local council who must be of a definite professional standing. The law requires that he shall be a registered medical practitioner invariably, which means that he shall have gone through the ordinary course of medical education and have passed such examinations as qualify him to practise as a medical man in this country. Since the year 1891 a medical officer of health elected to a town or district which has a population of as many as 50,000 must have also an additional diploma in the special subjects embraced in that branch of his profession known as state medicine or public health, or in the alternative have held previous to the year 1892 a post as medical officer of health to a district with a population of not less than 20,000. Besides the medical officer of health the sanitary authority must engage the services of an inspector of nuisances or sanitary inspector, with a sufficient number of assistants. These act more or less under the instructions of the medical officer of health as the local council may direct. As a rule only half the salary of the medical officer of health and of the chief inspector of nuisances is paid by the local council, the other half being paid out of State funds through the county council by order of the Local Government Board, and the Local Government Board retains some right to a demand upon the services of the medical officer of health, directs him to send the Board copies of his chief reports, and sometimes calls upon him directly to make a report upon some subject affecting his locality. The Local Government Board also prescribes the general duties of the medical officer of health as well as those of the inspector of nuisances. Broadly, the duties of a medical officer of health consist in keeping himself fully informed of all the influences affecting the health of his district and in advising his council upon all the things requiring to be done to maintain and improve the public health. This requires him to keep a constant eye upon the conditions existing through inspections made by himself and through such information as he obtains from the reports of the sanitary inspectors. His duties also involve numerous specific executive and other works, whether connected with the management of cases of infectious disease and their treatment in the isolation hospital, the keeping of the vital statistics of the district and taking action in connexion with what he learns from the returns made to him by the registrar of births and deaths, the inspection of the food-supply with intent to seize any article of food unfit for consumption, the superintendence of the water-supply as to its quality and fitness for general use, the health of school children especially as to infectious conditions, the condition of dwelling-houses and the certification of houses unfit for habitation, filthy and unwholesome, infected or overcrowded, and numerous other matters of related nature. He carries out the instructions of his council which arise out of the advice he gives. It is rare for his council to be in a position to give him instructions which do not arise out of his own representations. The medical officer of health, however, only does all these things to their proper and full extent when he is giving his whole time to this special work—when, in fact, he is acting the part of a specialist. This, unfortunately, is not always the case. The districts, urban and rural, that are governed by councils who are sanitary authorities, each of which must employ a medical officer of health, are of varying size and importance. It is open to the councils of the smaller districts which are contiguous to one another to combine and elect a medical officer of health to serve the combination, but not a great many of such combinations have been formed and there are innumerable small separate sanitary districts each employing a local medical man to give whatever time he thinks fit in return for a small salary. He gives little time and little interest and, as a rule, possesses next to none of that expert knowledge possessed by the medical man who gives his life's time to this special work and has every item of it at his fingers' ends. Under these conditions the smaller local councils acting as sanitary authorities are at a great loss. The council is absolutely dependent upon the medical officer of health to advise and to lead it, and without him is helpless in dealing with any important matter affecting public health. In many of the smaller districts this officer rarely attends the meeting even to give its members the benefit of the little knowledge he has, and the reports of the sayings and doings of the council are often quite comic to anyone who understands the import of the business. But, generally speaking, for want of a leader and adviser to bring matters before the council, nothing is done from month to month and year to year. The appointment of inspector of nuisances in these districts is worse than that of medical officer of health, for the latter must be a medical practitioner and as such is bound to be an educated person, but the inspector may be anybody. He may be, and sometimes is, a shoemaker, an auctioneer, or an odd farm hand for whom one of the members of the council wants to find a job. The result is that public health work in many of the rural districts and smallest urban districts is little better than a broad farce and a waste of public money in the maintenance of a pure pretence.

In the larger towns and combined rural districts where the medical officer of health is a sanitary specialist, giving his whole professional time to the duties, and is seconded by a proper staff of trained inspectors and assistants, the vastly improved health conditions which have been effected and are being effected, speak eloquently for the utility of the sanitary officer when he is the real expert he needs to be. The residents of these towns which have an effective public health department located at the municipal offices, to the responsible head of which they can apply at any time as to a friendly expert for counsel upon health matters, or to have their complaints attended to, are beginning to appreciate the value of the convenience and advantage of living in such a town as compared to living in a town which is less well found in these respects.

The position of the public health officer is, however, at the best seldom entirely a pleasant and satisfactory one. It must be remembered that his action on behalf of the public is constantly opposed to the financial interests of one and another. On the council itself, in whose service he is supposed to act, there will often be sitting members against whose property and interests he is bound to take action if he does his duty honestly. The efficient medical officer of health looks over the heads of his council to the public beyond and considers himself to be serving the public rather than the council, and it is necessary for him to take this view.

In return for action by the sanitary officer taken on behalf of the public against private individuals the officer is inevitably treated to considerable personal dislike, and there is always a party scheming to get the active officer turned out of his post. The system which is commonly in force of engaging the medical officer of health and chief sanitary inspector for a limited period, which usually varies from one to three years, at the end of which re-election has to be sought, gives to the opponents of the officer and to those generally against whom he has had to take active measures a fine opportunity for ousting him from his office. It is a very rare thing for a medical officer of health to be directly discharged, because this cannot be done without a definite reason, but not to re-appoint a man requires no other reason than that there is another candidate for the post. This insecurity of tenure of office of the chief public health officers has a very baneful influence upon the assiduity with which they may be expected to carry out their duties. There is a tendency on the part of the officer to order his conduct so as not to offend the councillors or their friends and thus to avoid being turned out of his post. Independent action on the part of a medical officer of health can only be expected from a man who has been appointed without stated term, and who consequently has no fear of suffering personal injury by being turned out of his post without sufficient reason or by being superseded when only appointed for a term. The very mean treatment that is often dealt out by a council to its energetic public health officers is also a cause of slackening of effort on their part. Thus, as may well be supposed, the council, a portion of whose members are smarting under some action directed against their individual interests or the interests of their friends and relations, is not likely to view with unanimous favour an application for increase of staff or increase of salary on the part of the officer, and the shabby treatment to which the officer is often otherwise exposed at the hands of the council must have a depressing effect upon his activity and determination for good work in the public interest. Public health work depends upon the ability and will of the officers, but the behaviour of councils towards their public health officials often goes far towards destroying the goodwill and public spirit that are so essential, and it is to be feared that some of the weaker men have grown tired of the constant battle which is required of them and have quitted the arena of hard knocks for the ease and greater personal profit of subservient complaisance. Complaints often arise of the ineffectiveness for sanitary work of the local council; the foregoing remarks should in some part explain the cause of the deficiency. It is of very slight advantage for new laws to be passed or new sanitary by-laws to be forced upon local councils for their acceptance, whether in relation to that much-talked of question, "the housing of the working classes," or any other public health subject, whilst such causes of weakness remain in the local administration—at least, this is true of a very large proportion of the country where the provisions of both laws and by-laws are exclusively limited to those printed pages which lie in the proud possession of the local clerk upon some high and dusty shelf, a subject for study and understanding for no one, and with no likelihood of ever being put into active operation.

There remains to consider briefly what alterations the foregoing remarks suggest both in regard to the status of the sanitary authority and that of the sanitary officer. The strong report of the Select Committee on the Housing of the Working Classes Acts Amendment Bill, presided over by Sir John Dickson Poynder, which report was presented to the House of Commons and ordered to be printed in December last, must be considered to have brought to a head an important matter that has for long been the subject of desultory and indeterminate action. This committee sitting to inquire into the housing question appears soon to have discovered the hopelessness of any effective administration of a Housing Act by the existing rural district councils and the officers whom, in the capacity of sanitary authorities, they have appointed to serve them. Evidence was given before the committee, and any amount more of similar evidence could have been obtained, which utterly condemns the present sanitary administration in rural districts. The committee seems to have limited its inquiry to rural district councils, which amounts to an omission, as an inquiry into the mode of working of many urban councils would have resulted in a similar condemnation, and the question of rural housing is not unconnected, at least, with the smaller urban districts. The committee sums up the results of its labours in 13 recommendations, those that are more radical and more nearly connected with the subject of this paper being as follows: To transfer the administration of the Public Health and Housing of the Working Classes Acts from the rural district councils to the county councils. To impose upon county councils as a statutory duty the appointment of a medical officer of health, or medical officers of health, and a sufficient number of sanitary inspectors for the purpose of carrying the public health statutes into execution. Proper qualifications for these officers to be prescribed by the Local Government Board and insisted upon. Officers to devote their whole time to the duties of their office and to hold their appointments during good behaviour. The instructions of the Local Government Board to the medical officers of health as to their duties to be of a more specific character. Simplification and codification of the sanitary laws. Statutory right of complaint direct to the Local Government Board to be given to a local council, or any four householders, in case of default by the county council, and the Local Government Board to be given power to enforce its requirements by mandamus. Appointment by Local Government Board of a special housing and public health department with a staff of travelling sanitary and housing in- pervise the administration of the public health and housing laws by the county councils and their executive officers.

In considering in the light of an intimate knowledge of the matter these recommendations of the Select Committee a doubt arises in the mind as to the advisability of making the county council the local sanitary authority. Inasmuch as many of the same men who constitute the rural and smaller urban councils sit upon the county councils, and as one has experience of the county council having been worked in a similar way to the more local council for the benefit of private interests, it would appear as if the self-same disability attaches to the larger local council as to the smaller. In connexion with the public health powers which they already possess, it cannot be said that the county councils as a whole have in the least distinguished themselves during the period of their existence. The county council is often to a great extent dominated by one person and he not always of a character free from prejudices inimical to sanitary progress. The Select Committee seems partly to appreciate these facts, as evidenced by its recommendation for a statutory power of complaint over the head of the county council to the Local Government Board. Nor does the county council appeal to one as representing that distributive equality which is required. The counties vary immensely in size, population, and importance, and it would not be appropriate nor lead to equal and regular working to have the country divided into such extremely unequal sanitary divisions as is represented by the counties. If the recommendations of the Special Committee become law, unless specific provisions in the Act were made for dividing up and managing each county, great irregularities would be certain to result and England would be as far from a properly systematised sanitary administration as it is at the present time. It is not to the councils at this juncture that special attention needs to be directed so much as to the officers. The council may to some extent control and check the officer, but dependence has to be placed entirely upon the officer to bring in information and advice as to what is required, to show how required work can be carried out, and to see that it is carried out properly. The medical officer of health must be prepared to accept the responsibility of being an expert leader and he must be acknowledged as such. The local council is secondary. It can be organised at pleasure, so long as there is a superior and independent authority to whom the officers can appeal in all cases of delayed and doubtful conduct on the part of the local council. This superior authority must have power to get its own ruling carried out without delay.

The Select Committee's recommendation is too intricate. There are to be officers of the Local Government Board and officers of the county council responsible for the same work. This will lead to continual differences and quarrels. The local officer will consider himself in the best position to form an opinion, and indeed so he generally must be, and it is not likely that he will brook interference by a Local Government Board inspector whose qualifications are no higher than his own. The proposition to make the ruling of the Local Government Board effective by a mandamus obtained from the High Court of Justice is not sufficient, if the mandamus is to be in the usual form of an order to the local council to carry out the work required to be done. A county council can snap its fingers in the faces of the entire judiciary, for to commit to prison a whole county council for contempt, let the deed or neglect be what it may, is impracticable. The superior authority must itself have power to carry out the work if need be and to charge it to the source of revenue upon which it would ordinarily fall. The better plan would seem to be to divide the country up into sanitary districts of such convenient size and population as to permit of facility in their administration and to place over these districts local sanitary committees. Such committees might be formed from the existing district councils by combining where necessary a sufficient number of them together and allowing them to elect a representative sanitary committee. This system is so far already in operation in those cases where the present legal option to unite into a combination for appointing a medical officer of health has been taken advantage of by adjacent local councils, although these existing combinations cannot be taken as patterns of what is required because the component councils do not transfer their powers and responsibilities to the representative committee which is consequently of little use, and, as a matter of fact, rarely meets. But here comes the essential innovation; the local chief sanitary officers must be appointed by the Local Government Board and must report directly to the Local Government Board as well as to the local sanitary committee, which will now be the local sanitary authority. The only possible alternative is that the sanitary laws shall be administered—at all events, for the rural and smaller urban districts—by the Central Government Department itself. In either case the Central Department will require powers to carry out in local districts the works upon which they determine in some such manner as that above indicated. If this central department be the Local Government Board a great deal of extra work will be brought to an office that is already supercharged, and no doubt a subdepartment will require to be formed and to be well officered in accordance with the recommendation of Sir John Dickson Poynder's Select Committee, but the national importance of health matters would seem to indicate that ultimately a special Government department, perhaps bearing the title of the Department of Public Health, will require to be formed.

MEDICINE AND THE LAW.

Potters' Asthma.

AT Stoke recently a meeting was held of employers in the pottery industry to consider the effect which the recent Workmen's Compensation Act will have upon their trade should "potters' asthma" be included in the "accidents" for which the master is to be liable to compensate the workman. A proposition on the subject was carried unanimously that—

> The disability caused by the inhalation of clay dust among pottery workers has been steadily diminishing for many years, owing to improved workshop conditions and the provisions of the Factory Acts regulating the age at which work may be commenced, and it can no longer be regarded as a serious risk to the worker.

It was pointed out in support of this motion that the effect of the inclusion of the disease in the schedule of the Act would be to compel the employers to discharge all workmen whose physical condition might render them more likely than their stronger fellows to contract it, and it was in consequence of arguments such as these that the motion was carried and that the meeting declared itself in favour of the enforcement of preventive measures rather than of compensation. There is a good deal to be said in support of such a contention. The compelling of the employer to take all the precautions that science can reasonably suggest in order to make safe a manufacture in which thousands are employed is, on the face of it, more just than ordering him to pay what may be looked on as a heavy fine inflicted not on account of any default on his part but because a workman has neglected to protect himself, or has been allowed to work when he might more prudently have been discharged. The insurance companies will no doubt insist upon all workmen being got rid of who may be thought to be in any way liable to "accidents" for which compensation must be paid.

The Edalji Case.

The report of the committee appointed to consider the extraordinary case of Mr. Edalji (the epithet is the committee's own) has now been made public, together with the letter from the Home Secretary to Sir Arthur Wilson, the chairman of the committee, which sets out his decision based upon the committee's report and upon reasons which he gives in it. Neither can be described as an illuminating document, so far as the perpetration of the outrages of which Mr. Edalji was convicted are concerned. The identity of their author and his methods remain enveloped in mystery and we only know that after careful investigation the three gentlemen appointed to inquire as to the complicity of Edalji are of the opinion that "the conviction was unsatisfactory" and that "after a most careful consideration of all the facts and printed evidence" placed before them they "cannot agree with the verdict of the jury" so far as it found the prisoner guilty of the crime for which he was indicted. On the other hand, they cannot bring themselves to disagree with the finding at the point where they have to assume it to imply the jury's belief that Mr. Edalji wrote certain letters. The members of the committee are not prepared to say that these were not the work of the accused, but they consider that assuming him to have written them too much weight was attached to them as evidence of his guilt with regard to the crime of maiming animals. According to established practice there must be proof of innocence before there can be a Royal pardon, but the Home Secretary has decided to break through the customary restrictions in what he describes as a "very exceptional case, and to advise His Majesty, as an act of Royal clemency, to grant a free pardon," without, however, recc mending any compensation in respect of a conviction which it is considered that letters attributable to hims may have been responsible. If we pass from the questi of the letters to the other points dealt with in t report we find that to a large extent the conviction the late prisoner was based upon evidence of a scienti character, and equally that a great deal of the sympat with him and much of the distrust with regard to t accuracy of the jury's verdict have been due to medic opinions as to the bearing of certain defects in his eyesig upon his probable power to commit the acts alleged again him. With regard to the first of these matters the police Staffordshire, and with them those of other counties, hav we hope, received useful lessons in the course of the pr longed agitation which has followed this case and from th report of the committee. There was a jacket upon which medical witness found stains of mammalian blood and als hairs, which, it was suggested, were those of an anima which had been mutilated. There was also an allegation o hairs upon a razor. The presence of the hairs at the tim when the coat and razor were first taken possession of by th police was emphatically denied by witnesses for the prisone who had then seen them in the hands of the officers. It was therefore essential to establish that these *pièces de conviction* reached the scientific witnesses in precisely the condition in which they were discovered at the house of the accused. Clearly the proper course for the police on all such occasions when it is possible to do so, must be to inclose the objects taken in clean paper or other wrapping material, in the presence, if possible, of the accused or of his friends, to tie the parcel securely with string, and to seal the string. The analogy between such a proceeding and the taking of samples of food stuffs need hardly be dwelt upon. In such cases as that under discussion the expert witness would himself cut the string and would produce it in court with the seals intact should any question arise, such as those which were raised by the relatives of Mr. Edalji. This course would prevent accidental interference with the objects kept for examination and would render deliberate tampering with them difficult and improbable. With regard to the question of Mr. Edalji's eyesight, which has already been referred to in THE LANCET,[1] from the point of view of those who consider that his physical infirmity alone was demonstrative of his innocence, the committee's report is as follows:—

> In some of the communications addressed to the Home Office on Edalji's behalf much stress has been laid upon the condition of his eyesight, which, it has been said, was such as to make it impossible that he could have traversed the route suggested on a dark night. Whether the question of eyesight was brought before the jury at the trial we do not positively know, but we can find no indication that it was. If the prisoner's advisers had attached importance to it, it certainly would have been relied upon. We have carefully considered the report of the eminent expert who examined Edalji in prison and the opinions of oculists that have been laid before us, and the materials now collected appear to us entirely insufficient to establish the alleged impossibility.

We may therefore congratulate Mr. Edalji on the formal removal of the stigma of conviction with its attendant disqualifications for success in civil life and those associated with him in the effort to establish his innocence so far as their efforts have been rewarded with success. His case, however, can hardly be said to have been cleared up in a manner completely satisfactory and the authorship and mode of perpetration of the cruel deeds for which he has suffered penal servitude will have to remain, for the present at all events, among the unsolved mysteries of modern crime.

---

[1] THE LANCET, Jan. 19th, 1907, p. 169.

WIMBLEDON COTTAGE HOSPITAL.—The thirty-seventh annual report of the Wimbledon Cottage Hospital shows a satisfactory financial condition for the past year, during which 182 patients were treated in the hospital at an average daily cost of 3*s.* 9*d.* per head. The report is largely concerned with the proposal to replace this and the South Wimbledon and Merton Cottage Hospital by one larger central building. Although this scheme has the support of the Metropolitan Sunday and Saturday Hospital Funds it appears that local opinion in Wimbledon is by no means unanimous in its favour and the hospital committee has appointed a subcommittee to report on this matter; until it is settled the disposition of a fund raised to commemorate the long and valuable services of the late Mr. Robert T. Poole Collyns as medical officer to the hospital must necessarily remain in abeyance.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Sanitary Circumstances and Administration of the Trowbridge Urban District, with special reference to the appointment of an Inspector of Nuisances, by Dr. R. J. REECE.[1]—The urban district of Trowbridge in Wiltshire has a population of about 12,000. Trowbridge is an important milk-distributing centre and a market town, and various industries are carried on there, the chief being pig-killing, bacon-curing, and cloth-weaving. Much of the town is old and closely built over, and Dr. Reece, in describing the housing conditions and the sanitary circumstances of the dwellings, points to many matters which require attention from the local authority; in particular there are mentioned the dilapidation of much of the poorer house property, the want of paving in backyards, and the dampness of walls. Closet accommodation is often insufficient and flushing tanks are rarely provided. Yard-gullies are frequently broken and have defective settings. The properties in question in most instances belong to small owners who cannot afford to do the necessary repairs or to non-resident landlords whose property is managed by agents. As the better class of the population move away to new houses in the suburbs the older dwellings, many of which are scarcely fit for human habitation, become occupied by a lower class of persons who are careless of their surroundings and ignorant of the rudiments of sanitation. In pointing out these and other insanitary conditions of Trowbridge Dr. Reece gives credit to the local authority and its officers for having carried out recent works of improvement in the town, notably the reconstruction of the sewerage system, and he mentions considerable advances which have been made during the past two or three years in dealing with insanitary property, supervising cowsheds and slaughter-houses, enforcing by-laws, and giving attention to food inspection. These advances have been made under the advice of the medical officer of health, Dr. J. Pearse, who was appointed five years ago, and were greatly facilitated by the appointment in 1904 of an energetic inspector of nuisances, who was required to give his whole time to the duties of the office. In June, 1906, however, the district council dismissed this inspector or, more strictly, declined to renew his yearly appointment on the ground that the work of inspector of nuisances could be sufficiently discharged by the assistant surveyor. Dr. Reece has no difficulty in showing that this is a retrograde step and that in Trowbridge the sanitary interests of the district require the whole time of an active and competent inspector. He adds that it is unfortunately necessary to consider the inspector's dismissal in the light of definite allegations which were made by the latter to the Local Government Board, these being to the effect that in the performance of his duties he had come into conflict with the private interests of several members of the council and had been interfered with by individual councillors in carrying out his duties. On reviewing the circumstances Dr. Reece concludes that the anticipation of saving expenditure has not been the sole factor instrumental in deciding that the inspector should be dispossessed of his office. It may be hoped that the inspector concerned, if he is still out of employment, will yet be able to derive some comfort from Dr. Reece's account of his work in Trowbridge.

On the General Sanitary Circumstances and Administration of the St. Neots and Eaton Socon Rural Districts, by Dr. R. DEANE SWEETING.[2]—In this report Dr. Sweeting gives a useful review of the sanitary circumstances of two large agricultural districts in Huntingdonshire. Special attention is paid to the condition of cottage property, local water-supplies and pollution of streams, and to the need for the supervision of slaughter-houses, cowsheds, and of new buildings generally. From the administrative side, perhaps the most notable part of the report is its reference to the arrangements made for carrying out the work of the medical officer of health. The position of a medical officer of health who has to be reappointed year by year is seldom satisfactory, and the drawbacks of such an arrangement are specially conspicuous where the medical officer gives his services under these conditions to several authorities and depends on his official work for a livelihood. In the present instance there has been for many years a single medical officer of health of the rural districts of St. Neots, Eaton Socon, Caxton, and Arrington, and of the St. Neots urban district. The council of each district renews the appointment every year and could at any time appoint a new officer without reference to the central authority. The contributions of the several districts together amount to £272 a year, of course without any provision for pension. The medical officer of health, who is not in practice, has no allowance for travelling over the wide area for which he is responsible. All the circumstances, in short, conspire to put difficulties in the way of any action by the medical officer of health which would conflict with the interests of members of his authorities or would necessitate frequent visits to portions of the districts which are far away from his home. These difficulties naturally do not diminish as the officer advances in years or with failure of his health. Dr. Sweeting has been careful to set out these considerations in criticising the sanitary administration of the districts which he has inspected. The report gives one more illustration of the need for legislation to enable satisfactory conditions of appointment and tenure of medical officers of health to be secured.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8671 births and 4630 deaths were registered during the week ending May 18th. The annual rate of mortality, which had continuously declined from 17·9 to 15·7 per 1000 in the six preceding weeks, further fell last week to 15·1 per 1000. During the first seven weeks of the current quarter the death-rate in these towns averaged 16·3 per 1000, the rate during the same period in London being 16·0. The lowest rates in the 76 towns last week were 8·4 in East Ham and in Leicester, 8·7 in Norwich, and 9·0 in Leyton; the rates in the other towns ranged upwards to 23·4 in Bolton, 23·6 in Gateshead, 23·7 in Rochdale, 24·0 in Merthyr Tydfil, and 24·1 in Middlesbrough. The 4630 deaths in the 76 towns showed a further decline of 186 from the numbers in recent weeks, and included 507 which were referred to the principal epidemic diseases, against 530 and 493 in the two previous weeks; of these, 212 resulted from measles, 144 from whooping-cough, 51 from diarrhœa, 41 from scarlet fever, 41 from diphtheria, 17 from "fever" (principally enteric), and one from small-pox. No death from any of these epidemic diseases was registered last week in Brighton, Norwich, Halifax, Stockport, Northampton, or in eight other smaller towns; the annual rate from these diseases, however, ranged upwards in the other towns to 3·6 in Rochdale, 4·3 in Sunderland, 6·3 in Bolton, and 7·8 in Hanley. The fatal cases of measles in the 76 towns, which had been 197 and 186 in the two preceding weeks, rose again last week to 212, the highest annual rates being 3·0 in Nottingham, 3·1 in Middlesbrough, 6·0 in Bolton, and 7·0 in Hanley. The 144 deaths from whooping-cough were 19 fewer than the number in the previous week; the greatest proportional mortality from this disease was recorded in Manchester, West Ham, Wigan, and Rochdale. "Fever" was proportionally most fatal in Rochdale, and diarrhœa in Sunderland, in Swansea, and in Wolverhampton; the deaths from scarlet fever and from diphtheria were not excessive in any of the 76 towns. There was one fatal case of small-pox in Southampton, but none in any other of the large towns; and no small-pox patients remained under treatment at the end of last week in the Metropolitan Asylums Hospitals. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 2672 and 2658 at the end of the two preceding weeks, had risen again to 2678 at the end of last week; 363 new cases were admitted during the week, against 346 and 349 in the two previous weeks. The deaths referred to pneumonia and other diseases of the respiratory organs in London, which had declined from 412 to 262 in the six preceding weeks, further fell to 235 in the week under notice, but were 14 in excess of the corrected average number in the corresponding week of the five years 1902–06. The causes of 42, or 0·9 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Manchester, Leeds, West Ham, Bradford, Newcastle-on-Tyne, and in 49 other of the 76 towns; the proportion of uncertified deaths, however, again showed considerable excess in Liverpool, Birmingham, Sunderland, Gateshead, Stockton-on-Tees, and Merthyr Tydfil.

[2] Ibid. No. 253. Price 4d.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 20·6, 19·9, and 19·3 per 1000 in the three previous weeks, rose again to 19·7 per 1000 in the week ending May 18th, and exceeded by 4·6 per 1000 the mean rate during the same week in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·0 in Perth and 16·3 in Edinburgh to 21·2 in Leith and 21·8 in Glasgow. The 685 deaths in the eight towns were 14 in excess of the number in the preceding week, and included 112 which were referred to the principal epidemic diseases, against 106 and 110 in the two previous weeks. These 112 deaths were equal to an annual rate of 3·2 per 1000, which exceeded by 1·5 per 1000 the rate from the principal epidemic diseases in the 76 English towns; they included 52 from whooping-cough, 41 from "fever," eight from measles, seven from diarrhœa, three from scarlet fever, and one from diphtheria, but not any from small-pox. The fatal cases of whooping-cough, which had been 52, 44, and 40 in the three preceding weeks, rose again last week to 52, of which 40 occurred in Glasgow, five in Edinburgh, three in Dundee, two in Aberdeen, and two in Paisley. The 41 deaths referred to "fever" exceeded by five the number in the previous week, and included 25 in Glasgow, seven in Leith, five in Edinburgh, two in Dundee, and two in Paisley; all these deaths, except two in Glasgow, were certified as from cerebro-spinal meningitis. The fatal cases of measles, which had been six and 12 in the two preceding weeks, declined again last week to eight, of which three occurred in Edinburgh, three in Leith, and two in Glasgow. Of the seven deaths from diarrhœa, two were registered in Glasgow, two in Edinburgh, and two in Dundee. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 127 and 107 in the two preceding weeks, were again 107 in the week under notice, and were 24 fewer than the number in the corresponding week of last year. The causes of 21, or 3·1 per cent., of the deaths registered in the eight towns during the week were not certified; in the 76 English towns the proportion of uncertified deaths did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 33·5, 26·4, and 24·0 per 1000 in the three preceding weeks, rose again to 26·7 in the week ending May 18th. During the first seven weeks of the current quarter the death-rate has averaged 27·5 per 1000; the rates during the same period did not exceed 16·0 in London and 17·9 in Edinburgh. The 200 deaths of Dublin residents registered during the week under notice exceeded by 20 the number in the previous week, and included seven which were referred to the principal epidemic diseases, against 29, 14, and 17 in the three preceding weeks; of these, four resulted from whooping-cough and one each from measles, diphtheria, and diarrhœa, but not any from small-pox, from scarlet fever, or from "fever." These seven deaths were equal to an annual rate of 0·9 per 1000, the rates during the same week from the principal epidemic diseases being 1·7 in London and 2·4 in Edinburgh. The fatal cases of whooping-cough, which had been 15, 10, and eight in the three preceding weeks, further declined to four in the week under notice. The 200 deaths from all causes included 30 of children under one year of age and 58 of persons aged upwards of 60 years; the deaths of infants showed a decline from the number in the preceding week, while those of elderly persons were in excess. One inquest case and two deaths from violence were registered; and 66, or 33 per cent., of the deaths occurred in public institutions. The causes of nine, or 4·5 per cent., of the deaths in Dublin last week were not certified; only one uncertified death was registered in London during the week, while in Edinburgh the percentage of such deaths was 4·6. The 158 deaths registered in Belfast during the week under notice included 21 which were referred to cerebro-spinal fever or cerebro-spinal meningitis.

VITAL STATISTICS OF LONDON DURING APRIL, 1907.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·9 per 1000 of the population, estimated at 4,758,218 persons in the middle of the year; the rates in the three preceding months were 6·8, 6·8, and 6·6 per 1000 respectively. The lowest rates last month were recorded in Kensington, Chelsea, the City of Westminster, St. Marylebone, Holborn, and Lambeth; and the highest rates in Shoreditch, Bethnal Green, Bermondsey, Battersea, and Woolwich. Three cases of small-pox, belonging respectively to St. Marylebone, Hampstead, and the City of London, were notified last month; and one small-pox patient was under treatment in a hospital of the Metropolitan Asylums Board at the end of the month. The prevalence of scarlet fever showed a considerable excess over that recorded in other recent months; this disease was proportionally most prevalent in Shoreditch, Stepney, Southwark, Battersea, Deptford, Greenwich, and Woolwich. The Metropolitan Asylums hospitals contained 2586 scarlet fever patients at the end of April, against 3116, 2829, and 2614 at the end of the three preceding months; the weekly admissions averaged 332, against 299, 323, and 312 in the three preceding months. Diphtheria was rather less prevalent in April than in the three preceding months; the greatest proportional prevalence of this disease occurred in Fulham, the City of London, Poplar, Bermondsey, Wandsworth, Deptford, and Woolwich. There were 946 diphtheria patients in the Metropolitan Asylums hospitals at the end of last month, against 921, 916, and 1012 at the end of the three preceding months; the weekly admissions averaged 119, against 124, 126, and 136 in the three preceding months. The prevalence of enteric fever showed but little variation last month; among the various metropolitan boroughs this disease was proportionally most prevalent in Hammersmith, the City of Westminster, Stoke Newington, Finsbury, the City of London, and Woolwich. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 100, 103, and 93 at the end of the three preceding months, had further declined to 66 at the end of last month; the weekly admissions averaged 12, against 14, 16, and 13 in the three preceding months. The 16 cases of puerperal fever notified during the month included two belonging to Hackney, two to Lambeth, and two to Wandsworth. Of the 16 cases notified as cerebro-spinal fever two belonged to Shoreditch, two to Bethnal Green, two to Poplar, two to Lambeth, and one each to St. Marylebone, St. Pancras, Islington, Holborn, Stepney, Southwark, Bermondsey, and Battersea.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided. During the four weeks ending April 27th the deaths of 5768 persons belonging to London were registered, equal to an annual rate of 15·8 per 1000; in the three preceding months the rates had been 19·9, 18·4, and 16·9 per 1000. The death-rates last month ranged from 10·6 in Woolwich, 12·3 in Hampstead, 12·6 in Lewisham, 12·8 in Wandsworth, 12·9 in the City of Westminster, and 13·1 in Stoke Newington to 19·9 in the City of London, 20·3 in Finsbury, 20·6 in Bermondsey, 20·8 in Bethnal Green, 22·2 in Holborn, and 24·7 in Shoreditch. The 5768 deaths from all causes in London last month included 594 that were attributed to the principal infectious diseases; of these, 194 resulted from measles, 39 from scarlet fever, 52 from diphtheria, 239 from whooping-cough, 16 from enteric fever, and 54 from diarrhœa. In addition to these 594 deaths one fatal case of cerebro-spinal fever belonging to Poplar was registered during the month. The lowest death-rates from the principal infectious diseases were recorded in the City of Westminster, Hampstead, Stoke Newington, Battersea, Lewisham, and Woolwich; and the highest rates in Chelsea, Holborn, Finsbury, Shoreditch,

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING APRIL, 1907.

(Specially compiled for THE LANCET.*)*

Cities and Boroughs.	Estimated population in the middle of 1907.	Notified Cases of Infectious Disease.											Deaths from Principal Infectious Diseases.											Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cerebro-spinal fever.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhoea.	Total.	Annual rate per 1000 persons living.

* Including membranous croup.

Bethnal Green, Bermondsey, and Greenwich. The 194 deaths from measles were 70 fewer than the corrected average number in the corresponding periods of the five preceding years; among the various boroughs this disease was proportionally most fatal in Hammersmith, Chelsea, Shoreditch, Poplar, Deptford, and Greenwich. The 39 fatal cases of scarlet fever were slightly in excess of the corrected average number; the greatest proportional mortality from this disease occurred in Paddington, Holborn, Bethnal Green, Shoreditch, Bermondsey, and Deptford. The 52 deaths from diphtheria were 10 below the average for the corresponding weeks of the five preceding years; this disease was proportionally most fatal in Shoreditch, Stepney, Battersea, Wandsworth, and Greenwich. The 239 fatal cases of whooping-cough were 64 in excess of the corrected average number; the greatest proportional mortality from this disease was recorded in Kensington, Holborn, Finsbury, Shoreditch, and Southwark. The 16 deaths from enteric fever were slightly below the average; four of these deaths belonged to Stepney and two each to Hammersmith, Southwark, and Bermondsey. The 54 fatal cases of diarrhœa were eight fewer than the average; the highest death-rates from this disease were in Paddington, Finsbury, Bethnal Green, and Stepney. In conclusion, it may be stated that the aggregate mortality from the principal infectious diseases in London last month was nearly 11 per cent. below the average.

Infant mortality, measured by the proportion of deaths under one year of age to registered births, was equal to 109 per 1000. The lowest rates were recorded in St. Marylebone, Hampstead, Stoke Newington, Holborn, Greenwich, Lewisham, and Woolwich; and the highest rates in Paddington, Hammersmith, Fulham, Shoreditch, Bethnal Green, Southwark, and Bermondsey.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 23rd, 1829.

CASE OF ANEURISM BY ANASTOMOSIS, TREATED BY VACCINATION.

By THOMAS F. DOWNING, M.D.

March 6. John Reardon, eleven months old, afflicted with a large nævus maternus, situated over the mastoid process of the temporal bone, extending upwards and inwards, including a portion of the integuments covering the back part of the ear. The mother states, it presented at birth a red discolouration of the skin, that it gradually enlarged, changed to a purple hue, became elevated, discharged blood, and, for the last month, increased with wonderful rapidity, owing, as she supposed, to the applications of poultices and fomentations.

It was first my intention to have extirpated the tumour by ligature, but recollecting that the attention of the profession was drawn by Mr. Earle, of Bartholomew's, to its treatment by vaccination, and as no surgeon (at least to my knowledge) in this country, had adopted the remedy, and as this was a case favourable for experiment, I was determined to try its effects. I accordingly inserted vaccine matter in several points on the surface of the nævus. At my visit on the eighth day, I found the tumour had become circumscribed, surrounded by a red halo, and bearing all the distinct characters of a true vaccine pustule. On the fourteenth day the scab was thrown off, leaving the base of the tumour nearly destroyed; for some days much suppuration followed, but in the course of three weeks from the commencement of the suppurative process, healthy granulations took place, and a perfect cure was effected.

The advantages of introducing cow-pox into the system, at the same time that disease is eradicated from it, are the important effects resulting from this mode of practice; and it must be duly estimated, when put into contrast with the means which have hitherto been employed. When the profuse hæmorrhage which generally follows excision by the knife, the destruction of parts when caustic is attempted, the almost invariable want of success, when the vessels leading to the tumour have been tied, and the irritation and convulsions which frequently follow the use of the ligature, are all taken into consideration, it is to be hoped that the curative means employed by vaccination, will be entitled to favourable notice, and that its efficacy will ultimately supersede the necessity of having recourse to the above painful remedies.

Fermoy, County Cork, April 27, 1829.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: F. W. Parker to the *Commonwealth*, on recommissioning; and H. J. Hadden to the *Sapphire*, additional for the *Sapphire II.* Staff Surgeons: R. H. Mornement to the *Commonwealth*, on recommissioning; H. Spicer to the *London;* and H. J. Chater to the *Forte*, on recommissioning. Surgeons: A. McCloy to the *Mutine*, on commissioning; and W. F. Archibald to the *Goliath*.

The undermentioned Surgeons have been promoted to the rank of Staff Surgeon in His Majesty's Fleet (dated May 15th), viz.:—Samuel Henry Woods, Percy Temple Sutcliffe, John Percival Handel Greenhalgh, Llewelyn Arnold Baiss, Charles Rowley Nicholson, Edward Theodore Burton, Robert Hughes, George Maurice Oswald Richards, Nelson Joseph Roche, John Henry Jones, Augustus John Laurie, and Penry Garnons Williams.

ARMY MEDICAL RESERVE.

The undermentioned to be Lieutenants on probation (dated May 1st, 1907): Charles Vere Nicoll, John Findon Murphy, Samuel Kilpatrick Adams, and Murray Ross Taylor.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Alexander MacKenzie to be Surgeon-Captain (dated Sept. 21st, 1906).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Banff: William Manson Fergusson to be Surgeon-Lieutenant (dated April 15th, 1907). 1st East Riding of Yorkshire: William Edwyn Falkingbridge Tinley to be Surgeon-Lieutenant (dated April 1st, 1907).

Rifle: 4th Volunteer Battalion the Queen's Own (Royal West Kent Regiment): Surgeon-Lieutenant F. B. Jefferiss to be Surgeon-Captain (dated Jan. 11th, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Scottish Command (Glasgow Companies): Lieutenant W. A. Burns to be Captain (dated May 1st, 1907).

DEATHS IN THE SERVICES.

Sir Joseph Fayrer, Bart., K.C.S.I., honorary physician and physician extraordinary to the King, on May 21st at his residence at Falmouth in his eighty-third year. He entered the Bengal Medical Service in 1850 and served in the Burmese War and throughout the Indian Mutiny and Defence of Lucknow. He was professor of the Medical College at Calcutta and subsequently President of the Medical Board at the India Office.

THE WHITSUN CAMPS AND MANŒUVRES AT SALISBURY PLAIN.

There has been a great muster of military forces this Whitsuntide on and about Salisbury Plain where the Volunteer corps, notably the Manchester Volunteer Infantry Brigade, have encamped in great force. The consolidated medical contingent from Manchester, some 550 strong, is composed of surgeons, compounders, and ambulance men. These manœuvres afford an opportunity also for the practical trial of new methods and appliances connected with the sanitary and medical services. With the establishment of the territorial army under Mr. Haldane's new scheme another organisation and order of things will soon be coming into operation. That Salisbury Plain has quite unusual advantages for military manœuvres and forms an ideal area as a big training ground for troops will be almost universally recognised. The troops under canvas have recently had a somewhat rough experience as far as weather conditions are concerned, what with the prevalence of a keen, cold wind and occasional showers of rain and hail, accompanied at night or early morning by slight frost. The camps have been inspected by many persons interested in all that concerns the army and army training—by Lord Roberts, who is staying with Sir Ian Hamilton, for example.

THE NAVY AND ARMY MALE NURSING COÖPERATION.

On June 3rd at 3.15 P.M. a meeting will be held at 10, Hill-street, Mayfair, the residence of Sir Richard and Lady Biddulph Martin, with the object of inaugurating a Navy and Army Male Nursing Association. The speakers will include Inspector-General Herbert M. Ellis, Director-General of the Royal Navy Medical Service; Surgeon-General Sir Alfred Keogh, Director-General of the Army Medical Service; Sir Richard Douglas Powell, Bart., President of the Royal College of Physicians of London; Mr. Henry Morris, President of the Royal College of Surgeons of England; and Sir Frederick Treves, Bart. The chief object of the association will be to enable first-class orderlies to find employment in civil nursing on leaving the Services; and, in addition, to provide a trustworthy nursing reserve for the country in time of war. Under a scheme which has been drawn up by Miss Ethel McCaul a sum of about £500 will be necessary to start the organisation which in 12 months would probably be self-supporting. Dr. C. M. H. Howell, 53, Queen Anne-street, W., is the honorary secretary.

INDIAN MEDICAL SERVICE AND CIVIL EMPLOYMENT.

Under instructions from the Secretary of State for India the Governor-General has issued an order to the effect that in future officers admitted to the Indian Medical Service will not be permitted to exercise choice of area for the purpose of civil employment but will be posted upon a consideration of all the circumstances, including, so far as possible, their own wishes, to one of the following civil areas: To Madras, including Madras and Burmah; to Bombay, including Bombay and Aden; to the Upper Provinces, including the United Provinces, Central Provinces, and the Punjab; to the Lower Provinces, including Bengal and Eastern Bengal and Assam. Though ordinarily employed within one of the above areas they will remain liable to employment elsewhere.

THE MANAGEMENT OF HOME MILITARY HOSPITALS IN TIME OF WAR.

After inspecting the St. John Ambulance Brigade camp at Stoneleigh Park, Warwickshire, on May 21st, Inspector-General Belgrave Ninnis, R.N., announced that the War Office had recently asked the St. John Ambulance Association whether in case of war that body could take charge of the military hospitals of the United Kingdom and Channel Islands. The association had expressed its willingness to undertake such duties. This arrangement would, of course, render the Royal Army Medical Corps free for service abroad.

ST. MARY'S HOSPITAL.—On May 18th the retirement of Dr. David B. Lees, the senior physician of St. Mary's Hospital, whose time-limit of service has recently expired, was made the occasion of an interesting little demonstration, in accordance with a custom which is now well-established. Dr. Lees was accompanied on his farewell round by a large number of St. Mary's men, including members of the staff and many of his former house physicians and clerks, as well as present students of the hospital. Dr. Lees taught on the cases in his beds with his accustomed lucidity and thoroughness and it happened that the material enabled him to recapitulate nearly all the points to which he has devoted much of his clinical energies both at St. Mary's Hospital and the Hospital for Sick Children, Great Ormond-street. The importance of accurately determining the size of the right heart, the value of leeching in treatment when it is enlarged, the importance of using very large doses of salicylates in acute rheumatism, and their control of its cardiac manifestations, the value of ice-bags in acute visceral inflammations, and the treatment of pulmonary tuberculosis by volatile antiseptic inhalations, all came under review. In a very happily expressed little speech at the end of the round in which he thanked his audience for their attendance he insisted on the importance of vigorous treatment founded on accurate diagnosis, and pointed out that the general practice of medicine is largely concerned in fighting the tubercle bacillus, the pneumococcus, and (he ventured to say) the rheumatococcus, and that these active diseases must be met by active measures. Dr. Lees then took farewell of his many friends present and was heartily cheered on leaving the hospital.

Correspondence.

"Audi alteram partem."

THE TEACHING OF COOKERY.

To the Editors of THE LANCET.

SIRS,—I am probably one of the oldest subscribers to THE LANCET and I have rarely been more interested in any of your articles than in reading the one on the teaching of cookery which appeared on April 20th. Although the teaching is very perfect in some towns and villages, and, as your article points out, very imperfect in others, a great advance has been made in obtaining a universal recognition of the importance of the subject. Nearly 47 years ago (October, 1860) in a report which I presented to the governors of the Preston Dispensary, after spending two years in visiting the houses of the poor, I asked the question could not a knowledge of cookery and housewifery be imparted at the school where the girl receives instruction in reading, writing, and arithmetic, and I hope that you will allow me to repeat the words in which I expressed my views.

> It is a very melancholy reflection that a great deal of the sickness and mortality which comes under our notice is owing to causes which might be removed. Anyone who has lived long in Preston cannot fail to be struck on taking a walk through the back parts of the town with the great improvements which have been made in the paving and draining of the streets, but on entering the dwellings of the poor his amazement will be still greater that, notwithstanding so much progress outside the houses, so little advancement has been made within them. The habitations of the bulk of our labouring poor and the nurseries of their children consist of dirty, ill-ventilated, and overcrowded rooms. As a class, too, the poor are quite ignorant of housewifery and cookery, and our wonder at this is diminished when we consider the way in which the wife of the working-man, who is the housekeeper and cook of the family, is brought up. At the age of eight years she begins to spend part of her day in the factory and the other part in a school. At 13 the whole of the day is occupied in the factory. At an early age she is married and in time has to undertake the cares and responsibilities of a family without having previously acquired any knowledge of housekeeping or cookery. Could not this knowledge upon which the comfort and welfare of so many depend be imparted at the school where the girl receives her instruction in reading, writing, and arithmetic? In the present day the education of the people is continually being insisted on and a net is spread to catch all classes. Why, then, should this most important branch of knowledge which has for its object the preservation of health and the prolongation of life be entirely neglected? The condition of the houses of the poor is also, I believe, one of the chief causes of intemperance, and what is a more prolific cause of disease than this? The poor workman returning home from his day's toil finds the atmosphere of his dwelling so polluted and his food so badly prepared that he hastens to the public-house, where everything is made attractive, to arouse himself by stimulants from the depression which domestic discomforts have produced in him. If the advocates of teetotalism would devote to the improvement of the houses of the poor more of the energy which they expend in preaching total abstinence their labours would probably be attended with even more satisfactory results than they at present accomplish. They seem to forget that the poor are constantly imbibing through their lungs and skin poisons almost as deadly as the alcohol which they so much cry down. By making the rules of health a part of the education of the working-classes the object in view might with a little perseverance be accomplished without having recourse to the invasion of the sanctity of private dwelling houses by inspectors of domestic nuisances. The late Sir Thomas Watson, in his admirable lectures on the "Principles and Practice of Physic," says: "On the outbreak of an epidemic of cholera the most stringent measures for the removal of acknowledged causes of disease would not be considered superfluous; why then should we wait for such a visitation before we commence our great work of sanitary reform? The cholera only makes its onslaught periodically, but the causes which have been alluded to are in daily and hourly operation, sowing the seeds of death, misery, and destruction all around us. Since the benefits to be derived from this reform are for the good of our common humanity, the work is one in which all parties may join; indeed, combination is absolutely necessary, for the removable causes of disease are only susceptible of extinction by the united efforts of the community."

I have no doubt that what I have said about the condition of the houses in the poorer parts of Preston is applicable to many other places. Your remarks on the value of food which is often thrown away recall an experience which I had a short time ago. I observed that at a moderately sized hotel a considerable quantity of bread, chicken, meat, and other food was left on the table and plates by visitors who evidently were unable to eat all that was placed before them. When I asked what became of this I was told that it was all thrown into a swill tub for pigs. I fortunately obtained permission to have it for a mission home for the children of depraved parents and I find that the bread is sufficient to feed 24 children during the latter half of the day without cutting into a loaf of fresh bread. There can be no doubt that the difficulty of feeding poor children would be materially lessened if the scraps of food which in many houses are thrown away as useless and worthless were utilised. I repeatedly mentioned to school inspectors and others the desirability of having female children instructed in housewifery and cookery, but it is only within the last few years that an earnest attempt has been made to give a systematic and practical training in these subjects. The full benefit of the teaching will not be realised until the Board of Education can see its way to make it compulsory for every female attending the elementary schools on reaching the age of 11 to receive efficient instruction in cookery and laundry work and at 12 in housewifery. I am afraid that the recent publication of the report of the alleged and inefficient teaching of domestic science will have a very deterrent effect on the minds of education committees who otherwise might be disposed to encourage and develop this instruction in the areas which they control. In conclusion, I cannot help expressing my regret that the report contains chiefly destructive criticism—a few glaring instances of inefficiency being quoted as types of the general work undertaken in this subject in certain districts, while very little or no commendation is given to the really good work which is most certainly attempted and accomplished in many parts of the country.

THE STATUS LYMPHATICUS.

To the Editors of THE LANCET.

SIRS,—Dr. L. Vintras in your issue of May 11th revives the old doctrine of states, temperaments, or diatheses. No doubt the recognition of different types of constitution with tendencies to special diseases is helpful. Three at least of Galen's nine temperaments besides his *εὐκρασία* or balanced health held their place in the text-books at any rate until a generation ago. I think it was Sir William Gull who remarked that the subjects of particular diseases had a family likeness; certainly many observers have been able to guess a man's disorder from his aspect and manner. But the comparative neglect of temperament in later British medicine to which Dr. Vintras alludes is capable of some explanation. Is it not due in large part to improved pathology, which has shown the true nature of many disorders, and so removed them from the class of uncertain constitutional states? and, secondly, to an unwillingness to generalise on conditions of which the causes are unknown? It is felt that in attempting to define temperaments and diatheses we are apt to stray into the land of obscurity and of assumptions. What one generation describes as a temperament consistent with health is found by another to have a definite pathology. Yet this neglect may be carried too far.

With regard to the status lymphaticus it may be questioned whether various disorders and tendencies to disorder are not included under this heading. Dr. Vintras quotes Trousseau's use of the term "lymphatic diathesis" in his ninety-first lecture. But surely this is in another sense. He is dealing with the etiology of adenia (lymphadenoma), and uses the expression "lymphatic diathesis" to represent the unknown cause of the disease, not to connote a state or temperament. Moreover, he lays stress on generalised enlargement of the lymphatic glands, a feature which finds no place in Dr. Vintras's clinical picture of the status lymphaticus. This clinical picture, although not without distinction, seems to include a diversity of conditions sometimes amounting to paradox. Its subjects combine slowness of habit with high intelligence; they are shy, yet genial; listless, yet greatly interested; their pulses are slow, yet apt to remain above 100 for days and even weeks. Dr. Vintras does not mention blood pressure. There is a more restricted class of persons, with deficient capillary fulness, with unstable blood pressure most often lower than the average, with excitable hearts, with weak muscles, and with proneness to effusions in the skin and serous cavities. Such persons are pale and have often been subjected to the strain of rapid bodily growth. The lymphatic circulation is sluggish. Albuminuria occurring in a cyclic form is often present. Strong reasons have been advanced for ascribing the albuminuria to a blood condition, of which the outstanding feature is deficiency in the coagulating power of that fluid, and this kind of albuminuria has been called "hæmatogenous."[1] Deficient coagulability of the blood has also been found in other individuals of the class described in whom albuminuria was not present. I would suggest that blood conditions, which are taking an ever larger part in pathology, will be found at the root of the so-called lymphatic diathesis. Some experience, which I hope to record later, in testing the coagulation by Wright's method impresses me with the *fluid* character of the blood in lymphatic subjects.

Weymouth-street, W., May 14th, 1907. R. HINGSTON FOX.

PHARYNGO-KERATOSIS TREATED BY APPLICATIONS OF SALICYLIC ACID IN SULPHO-RICINATE OF SODA.

To the Editors of THE LANCET.

SIRS,—I am sorry to trespass again on the hospitality of your columns, but Dr. W. Jobson Horne's letter in THE LANCET of May 11th, p. 1316, obliges me to make this further intrusion. The facts of the case are extremely simple and the correctness of my deduction must be obvious to any unbiased reader. At a stage when the condition of the two tonsils was identical (previous interrupted treatment having proved so far unavailing) a solution of salicylic acid in sulpho-ricinate of soda was applied daily by the patient to the right one, with the result of producing a marked diminution in the size and consistency of the keratotic points on it, the other tonsil remaining as before, and acting therefore as what is known in physiological experiments as a "control." The logical deduction from the fact is that the application was the cause of the improvement, the requirements of an experiment having been fully met. Dr. Jobson Horne is one of the secretaries of the London Laryngological Society and it is he who is responsible for the omission of the clear statement of this all-important fact in the report of my case, sent by him in his official capacity to the medical papers, thereby depriving it of its main interest. For this omission on his part I have received from the President of the Society a letter expressing the regret of the council for the injustice done, doubtless without intention, to my unpretentious communication. I am, Sirs, yours faithfully,

May 18th, 1907. DUNDAS GRANT.

PS.—I may mention that the improvement was steady, although slow, and for some months there has been scarcely anything visible which could be recognised as pharyngo-keratosis, while now there is none at all.

A NEW METHOD OF PERCUSSION.

To the Editors of THE LANCET.

SIRS,—In the notes from Budapest in your issue of May 18th mention is made of "A New Method of Percussion." For several years I occasionally used this method of percussion and have demonstrated it in classes on physical examination and in the wards. I very rarely employ this method now for the reason that, in chest work especially, it does not so well afford that appreciation of resistance which is so valuable a part of the information to be obtained by the ordinary method of percussion. It is, however, a useful variation when it is desired to localise exactly a small area of deficient resonance, and Dr. Janos Plesch deserves credit for drawing the attention of the profession to a useful addition to the ordinary methods of physical examination.

I am, Sirs, yours faithfully,
Harley-street, W., May 20th, 1907. J. EDWARD SQUIRE.

THE COLONIAL OFFICE AND THE PAYMENT OF MEDICAL EVIDENCE AT CORONERS' INQUESTS.

To the Editors of THE LANCET.

SIRS,—I beg to forward you the inclosed which appears to convey the situation. I was desired to attend an inquest and denied a fee. After practising a great many years it is a fresh experience to be examined as I was and not paid

---

The man was not even one of crew or passenger, but stevedore's man.—I am, Sirs, yours faithfully,

JAMES WAGHORN.

Singapore, April 24th, 1907.

[Copy.]

Colonial Secretary's Office,
Singapore, 8th January, 1907.

Sir,—I am directed to acknowledge the receipt of your letter of the 25th ultimo applying for a fee for your attendance at an inquest held by the coroner at Section 1, Tanjong Pagar Dock, on that date.

The coroner states that no formal inquest was held but that the proceedings consisted merely of an investigation on board the steamer, and the Government is advised that in the circumstances you are not entitled to the fee which is usually allowed in the case of medical practitioners who are called to give evidence at coroners' inquests.

I have the honour to be, Sir, your obedient servant,
E. L. Brockman,
For Colonial Secretary, Straits Settlements.

Dr. J. Waghorn, s.s. *Kut Sang*,
care of Messrs. Jardine, Matheson, and Co., Hong-Kong.

THE TREATMENT OF THE ROYAL NAVY MEDICAL SERVICE.

To the Editors of The Lancet.
